PROYECTO NUEVO PUERTO MANZANILLO
MUESTREO DE FLORA
SITIOS EN EL AREA DEL PROYECTO

CENTROIDE DE SITIOS DE 500 M2 PARA SELVA BAJA CADUCIFOLIA
CENTROIDE DE SITIOS DE 100 M2 PARA MANGLAR

SITIO	X	Y	VEGETACION
1	577912	2105544	Selva baja caducifolia

51	Arbóreo	51	*Luehea candida*	Algodoncillo	SBC
52	Arbóreo	52	*Lysiloma microphyllum*	Tepemezquite	SBC
53	Arbóreo	53	*Manihot aesculifolia*	Manitas	SBC
54	Arbóreo	54	*Margaritaria nobilis*	Vidrillo	SBC
55	Arbóreo	55	*Muntingia calabura*	Juanito	SBC
56	Arbóreo	56	*Myroxylon horridum*	Huizcoron	SBC
57	Arbóreo	57	*Nectandra salicifolia*	Aguacatillo	SBC
58	Arbóreo	58	*Phyllanthus mocinianus*	Oreja de raton	SBC
59	Arbóreo	59	*Piptadenia flava*	Sierrilla arborea	SBC
60	Arbóreo	60	*Pithecellobium dulce*	Guamuchil	SBC
61	Arbóreo	61	*Pithecellobium lanceolatum*	Timuchil	SBC
62	Arbóreo	62	*Platymiscium lasiocarpum*	Granadillo	SBC
63	Arbóreo	63	*Plumeria rubra*	Sacaloxochil	SBC
64	Arbóreo	64	*Psidium sartorianum*	Guayabillo	SBC
65	Arbóreo	65	*Recchia mexicana*	Manzanito	SBC
66	Arbóreo	66	*Roseodendron donnell-smithii*	Primavera	SBC
67	Arbóreo	67	*Sapindus saponaria*	Bolitario	SBC
68	Arbóreo	68	*Sapium macrocarpum*	Higuerilla brava	SBC
69	Arbóreo	69	*Sideroxylon capiri*	Capire	SBC
70	Arbóreo	70	*Sideroxylon persimile*	Huizilacate negro	SBC
71	Arbóreo	71	*Spondia purpurea*	Ciruelo	SBC
72	Arbóreo	72	*Stemmadenia tomentosa*	San antonio	SBC
73	Arbóreo	73	*Styrax ramirezii*	Azajar	SBC
74	Arbóreo	74	*Tabebuia chrysantha*	Mapilla	SBC
75	Arbóreo	75	*Thouinia serrata*	Huesillo de cerro	SBC
76	Arbóreo	76	*Trichilia americana*	Cola de zorra	SBC
77	Arbóreo	77	*Trophis racemosa*	Falso ramon	SBC
78	Arbóreo	78	*Zanthoxylum arborescens*	Zorrillo	SBC
79	Arbustivo	1	*Acacia farnesiana*	Huizache	SBC
80	Arbustivo	2	*Acacia tenuifolia*	Aguilillo	SBC
81	Arbustivo	3	*Aphelandra scabra*	Cola de gallo	SBC
82	Arbustivo	4	*Ayenia aculeata*	Sierrilla cuadrada	SBC
83	Arbustivo	5	*Bauhinia divaricata*	Pata de cabra	SBC
84	Arbustivo	6	*Bonellia macrocarpa*	Pica pendejos	SBC
85	Arbustivo	7	*Caesalpinia pulcherrima*	Tabachincillo	SBC
86	Arbustivo	8	*Celtis iguanaea*	Granjeno	SBC
87	Arbustivo	9	*Cnidoscolus multilobus*	Quemadora palmaeda	SBC
88	Arbustivo	10	*Crotalaria micans*	Sonajilla lanceolada	SBC
89	Arbustivo	11	*Croton suberosus*	Mata corchosa	SBC

90	Arbustivo	12	*Eupatorium glabratum*	Arbusto de la paloma	SBC
91	Arbustivo	13	*Guardiola tulocarpus*	Vara prieta	SBC
92	Arbustivo	14	*Guettarda elliptica*	Limoncillo tronco de guayabo	SBC
93	Arbustivo	15	*Hyperbaena ilicifolia*	Gorda dura	SBC
94	Arbustivo	16	*Indigofera suffruticosa*	Senna arbustiva añil	SBC
95	Arbustivo	17	*Lasiacis divaricata*	Otatillo	SBC
96	Arbustivo	18	*Lasianthaea fruticosa*	Vara san josé	SBC
97	Arbustivo	19	*Malvaviscus arboreus*	Obelisco de cerro	SBC
98	Arbustivo	20	*Manihot chlorosticta*	Manihot	SBC
99	Arbustivo	21	*Piper hispidum*	Piper lanceolado	SBC
100	Arbustivo	22	*Pisonia aculeata*	Chorumo colmillo de puerco	SBC
101	Arbustivo	23	*Randia armata*	Crucillo	SBC
102	Arbustivo	24	*Rauvolfia tetraphylla*	Sarna de perro	SBC
103	Arbustivo	25	*Rhipidocladum racemiflorum*	Carricillo otatillo de cerro	SBC
104	Arbustivo	26	*Roldana chapalensis*	Rondala	SBC
105	Arbustivo	27	*Urera caracasana*	Quemadora carascana	SBC
106	Arbustivo	28	*Verbesina oligantha*	Vara blanca	SBC
107	Herbaceo	1	*Abutilon trisulcatum*	Acapan	SBC
108	Herbaceo	2	*Acalypha mexicana*	Cancerina	SBC
109	Herbaceo	3	*Ambrosia psilostachya*	Hierba amargosilla	SBC
110	Herbaceo	4	*Antigonon flavescens*	Zarzal morado	SBC
111	Herbaceo	5	*Aphelandra lineariloba*	Afelandras	SBC
112	Herbaceo	6	*Calathea atropurpurea*	Tacuachin	SBC
113	Herbaceo	7	*Commelina diffusa*	Tripa de Pollo	SBC
114	Herbaceo	8	*Costus pulverulentus*	Caña de indio	SBC
115	Herbaceo	9	*Crinum erubescens*	Lirio del valle	SBC
116	Herbaceo	10	*Cucurbita moschata*	Calabacilla	SBC
117	Herbaceo	11	*Dicliptera resupinata*	Maleza de las lomas	SBC
118	Herbaceo	13	*Elytraria imbricata*	Cordoncillo	SBC
119	Herbaceo	14	*Gronovia scandens*	Arroz de leche	SBC
120	Herbaceo	15	*Hyptis suaveolens*	Chan	SBC
121	Herbaceo	16	*Indigofera densiflora*	Frijolillo vaina	SBC
122	Herbaceo	17	*Ipomoea carnea*	Amapola rosa	SBC
123	Herbaceo	18	*Ipomoea purpurea*	Campanilla morada	SBC
124	Herbaceo	19	*Lasiacis nigra*	Pasto bolita	SBC
125	Herbaceo	20	*Lasiacis procerrima*	Carricillo	SBC
126	Herbaceo	21	*Lygodium venustum*	Helecho enredadera	SBC
127	Herbaceo	22	*Macroptilium atropurpureum*	Frijolillo	SBC
128	Herbaceo	23	*Mimosa pudica*	Sierrilla	SBC
129	Herbaceo	24	*Momordica charantia*	Pepinillo amarillo	SBC
130	Herbaceo	25	*Mucuna pruriens*	Pica pica	SBC
131	Herbaceo	26	*Oplismenus compositus*	Pasto huevero	SBC
132	Herbaceo	27	*Panicum maximum*	Pasto tanzania	SBC
133	Herbaceo	28	*Portulaca oleracea*	Verdolaga	SBC
134	Herbaceo	29	*Sicyos barbatus*	Chayotillo tronador	SBC
135	Herbaceo	30	*Sida glabra*	Guinar escobero	SBC

136	Herbaceo	31	*Sporobolus virginicus*	Pasto amarillo	SBC
137	Herbaceo	32	*Tribulus cistoides*	Abrojo pegajoso	SBC
138	Otras especies	1	*Acanthocereus tetragonus*	Tazajo	SBC
139	Otras especies	2	*Adenopodia gymnantha*	Bejuco sierrilla	SBC
140	Otras especies	3	*Ampelocissus acapulcensis*	Uva cimarrona	SBC
141	Otras especies	4	*Amphilophium crucigerum*	Bejuco corona	SBC
142	Otras especies	5	*Aristolochia taliscana*	Bejuco corchozo	SBC
143	Otras especies	6	*Cissus verticillata*	Bejuco tripa de vaca	SBC
144	Otras especies	7	*Cocos nucifera*	Palma de coco	SBC
145	Otras especies	8	*Combretum fruticosum*	Bejuco peineta	SBC
146	Otras especies	9	*Combretum fruticosum*	Bejuco corona	SBC
147	Otras especies	10	*Dioscorea mexicana*	Camote de cerro	SBC
148	Otras especies	11	*Mimosa albida*	Sierrilla	SBC
149	Otras especies	12	*Pachycereus pecten-aboriginum*	Cactus organo pitayo	SBC
150	Otras especies	13	*Paullinia sessiliflora*	Bejuco Costillon	SBC
151	Otras especies	14	*Pilosocereus purpusii*	Pitayo serpetinum	SBC
152	Otras especies	15	*Scaevola plumieri*	Bejuco costero	SBC
153	Otras especies	16	*Serjania brachycarpa*	Bejuco serjania	SBC
154	Otras especies	17	*Smilax spinosa*	Bejuco alambre	SBC
155	Otras especies	18	*Stegnosperma cubense*	Bejuco de arena	SBC
156	Otras especies	19	*Tillandsia intermedia*	Tillandicia	SBC

LISTADO DE ESPECIES IDENTIFICADAS EN EL MUESTREO EN EL SAR

No.	Nombre Cientifico	Nombre Común	Estrato	SBC	SMS	BQ	M	VHH	DC	Tipos	Categoría	CITES
1	*Abutilon trisulcatum*	Acapan	Herbaceo	1						1		
2	*Acacia cochliacantha*	Espino blanco	Arbóreo	1						1		
3	*Acacia farnesiana*	Huizache	Arbustivo	1						1		
4	*Acacia glomerosa*	Espino monte	Arbóreo	1						1		
5	*Acacia hindsii*	Huizcolote	Arbóreo	1						1		
6	*Acacia macilenta*	Chacalcahuil	Arbóreo	1						1		
7	*Acacia tenuifolia*	Aguilillo	Arbustivo	1						1		
8	*Acalypha mexicana*	Cancerina	Herbaceo	1					1	2		
9	*Acanthocereus tetragonus*	Tazajo	Otras especies	1	1					2		Apendice II
10	*Adenopodia gymnantha*	Bejuco sierrilla	Otras especies	1	1					2		
11	*Adiantum concinnum*	Helecho bipinado	Herbaceo		1					1		
12	*Adiantum tricholepis*	Helecho dentado	Herbaceo		1	1				2		
13	*Aechmea bracteata*	Bromelia aserrada	Otras especies			1				1		
14	*Agonandra racemosa*	Chilcahuite	Arbóreo		1					1		
15	*Albizia occidentalis*	Parotilla china	Arbóreo	1	1					2	Amenazada (A)	
16	*Albizia tomentosa*	Parotilla Morada	Arbóreo	1						1		
17	*Alstonia longifolia*	Frijolillo doble	Arbóreo	1						1		
18	*Ambrosia psilostachya*	Hierba amargosilla	Herbaceo	1	1	1				3		
19	*Ampelocissus acapulcensis*	Uva cimarrona	Otras especies	1						1		
20	*Amphilophium crucigerum*	Bejuco corona	Otras especies	1	1					2		
21	*Amphipterygium adstringens*	Cuachalalate	Arbóreo	1						1		
22	*Andira inermis*	Almendro de río	Arbóreo		1					1		
23	*Annona purpurea*	Cabeza de negro	Arbóreo		1					1		
24	*Antigonon flavescens*	Zarzal morado	Herbaceo	1	1					2		
25	*Aphananthe monoica*	Chiillo / Palo barranco	Arbóreo	1	1					2		
26	*Aphelandra linearíloba*	Afelandras	Herbaceo	1						1		
27	*Aphelandra scabra*	Cola de gallo	Arbustivo	1	1					2		
28	*Apoplanesia paniculata*	Llora sangre de cerro	Arbóreo	1						1		
29	*Ardisia compressa*	Chico corriozo	Arbustivo		1					1		
30	*Aristolochia taliscana*	Bejuco corchozo	Otras especies	1	1					2		
31	*Astraea lobata*	Manzanita	herbáceo						1	1		
32	*Astronium graveolens*	Culebro	Arbóreo	1	1					2	Amenazada (A)	
33	*Attalea cohune*	Palma de cayaco	Otras especies		1					1	Protección especial	
34	*Avicennia germinans*	Mangle prieto	Arbóreo				1			1	Amenazada (A)	
35	*Ayenia aculeata*	Sierrilla cuadrada	Arbustivo	1						1		
36	*Batis maritima*	Saladilla	Herbaceo					1		1		
37	*Bauhinia divaricata*	Pata de cabra	Arbustivo	1						1		
38	*Blechum pyramidatum*	Cancerillo	Herbaceo			1				1		
39	*Bonellia macrocarpa*	Pica pendejos	Arbustivo	1						1		
40	*Bravaisia integerrima*	Mangle de cerro	Arbóreo	1						1	Amenazada (A)	
41	*Brosimum alicastrum*	Mojo	Arbóreo	1	1					2		
42	*Bursera copallifera*	Copal	Arbóreo	1		1				2		
43	*Bursera grandifolia*	Papelillo Verde	Arbóreo	1	1					2		
44	*Bursera sarcopoda*	Tecomaca	Arbóreo	1						1		
45	*Bursera simaruba*	Papelillo rojo	Arbóreo	1	1					2		
46	*Caesalpinia pulcherrima*	Tabachincillo	Arbustivo	1						1		
47	*Calathea atropurpurea*	Tacuachin	Herbaceo	1						1		
48	*Calliandra caeciliae*	Vara de angel	Arbustivo			1				1		
49	*Calophyllum brasiliense*	Palo maría	Arbóreo		1					1	Amenazada (A)	
50	*Canavalia rosea*	*Canavalia*	herbáceo						1	1		
51	*Cascabela ovata*	Ayoyote	Arbóreo	1						1		
52	*Casearia nitida*	Chamizo	Arbóreo	1	1					2		
53	*Casimiroa edulis*	Zapotillo	Arbóreo	1						1		
54	*Cecropia obtusifolia*	Trompetero	Arbóreo		1					1		
55	*Cedrela odorata*	Cedro rojo	Arbóreo		1	1				2	Protección especial (Pr)	Apendice II
56	*Ceiba aesculifolia*	Pochote	Arbóreo	1						1		
57	*Celtis iguanaea*	Granjeno	Arbustivo	1						1		
58	*Cenostigma eriostachys*	Iguanero de la costa	Arbóreo	1	1					2		
59	*Chloroleucon mangense*	Guayabillo borcelano	Arbóreo	1	1					2		
60	*Cissus microcarpa*	Bejuco tripa de vaca	Otras especies	1						1		
61	*Cissus verticillata*	Bejuco tripa de vaca	Otras especies	1		1				2		
62	*Clethra hartwegii*	Cucharo	Arbóreo		1					1		
63	*Cnidoscolus multilobus*	Quemadora palmaeda	Arbustivo	1						1		
64	*Cochlospermum vitifolium*	Panicua	Arbóreo	1		1				2		
65	*Cocos nucifera*	Palma de coco	Otras especies	1						1		
66	*Combretum fruticosum*	Bejuco corona	Otras especies	1						1		
67	*Commelina diffusa*	Tripa de Pollo	Herbaceo	1		1				2		
68	*Commicarpus scandens*	Bellesa del pacifico pegajosila	Arbustivo		1					1		
69	*Comocladia engleriana*	Hincha huevos	Arbóreo	1						1		
70	*Conium maculatum*	Cilantrillo	Herbaceo			1				1		
71	*Conocarpus erectus*	Mangle botoncillo	Arbóreo				1			1	Amenazada (A)	
72	*Cordia alliodora*	Botoncillo	Arbóreo	1	1					2		
73	*Cordia dentata*	Tamborcillo	Arbóreo	1						1		
74	*Cordia elaeagnoides*	Barcino	Arbóreo	1	1					2		
75	*Cordia gerascanthus*	Nance ogelato	Arbóreo	1						1		
76	*Costus pulverulentus*	Caña de indio	Herbaceo	1						1		
77	*Coulteria platyloba*	Coral	Arbóreo	1						1		
78	*Crataeva tapia*	Bulillo	Arbóreo	1						1		
79	*Crinum erubescens*	Lirio del valle	Herbaceo	1						1		
80	*Crotalaria micans*	Sonajilla lanceolada	Arbustivo	1						1		
81	*Croton suberosus*	Mata corchosa	Arbustivo	1						1		
82	*Cryosophila nana*	Palma escobera	Otras especies			1				1	Amenazada (A)	
83	*Cucurbita moschata*	Calabacilla	Herbaceo	1						1		
84	*Cupania dentata*	Palo acanalado	Arbóreo		1					1		
85	*Dendropanax arboreus*	Macarmina	Arbóreo		1					1		
86	*Desmodium Incanum*	Frijolillo arbustivo	Arbustivo			1				1		
87	*Dicliptera resupinata*	Maleza de las lomas	Herbaceo	1	1					2		
88	*Dioscorea mexicana*	Camote de cerro	Herbaceo	1						1		
89	*Diphysa americana*	Hormiguillo	Arbóreo	1						1		
90	*Elytraria imbricata*	Cordoncillo	Herbaceo	1	1	1				3		
91	*Enterolobium cyclocarpum*	Parota	Arbóreo	1	1	1				3		

92	*Erythrina americana*	Colorin	Arbóreo	1						1		
93	*Eupatorium glabratum*	Arbusto de la paloma	Arbustivo	1						1		
94	*Ficus cotinifolia*	Tescalama	Arbóreo		1					1		
95	*Ficus maxima*	Higuera blanca	Arbóreo		1					1		
96	*Ficus velutina*	Zalate	Arbóreo	1						1		
97	*Forchhammeria pallida*	Olivillo	Arbóreo	1	1					2		
98	*Galinsoga parviflora*	Manzanilla silvestre	Herbaceo		1	1				2		
99	*Gliricidia sepium*	Cacanahual	Arbóreo	1						1		
100	*Gronovia scandens*	Arroz de leche	Herbaceo	1						1		
101	*Guardiola tulocarpus*	Vara prieta	Arbustivo	1						1		
102	*Guazuma ulmifolia*	Guasima	Arbóreo	1	1					2		
103	*Guettarda elliptica*	Limoncillo tronco de guayabo	Arbustivo	1	1					2		
104	*Gyrocarpus jatrophifolius*	Rebelero	Arbóreo	1	1					2		
105	*Heliocarpus terebinthinaceus*	Majahua	Arbóreo	1	1	1				3		
106	*Hintonia latiflora*	Trepa chuy	Arbóreo	1						1		
107	*Hura polyandra*	Habillo	Arbóreo	1	1					2		
108	*Hyperbaena ilicifolia*	Gorda dura	Arbustivo	1						1		
109	*Hyptis suaveolens*	Chan	Herbaceo	1		1				2		
110	*Indigofera densiflora*	Frijolillo vaina	Herbaceo	1						1		
111	*Indigofera suffruticosa*	Senna arbustiva añil	Arbustivo	1						1		
112	*Inga eriocarpa*	Cuil	Arbóreo		1					1		
113	*Ipomoea carnea*	Amapola rosa	Herbaceo	1						1		
114	*Ipomoea murucoides*	Osote	Arbóreo	1						1		
115	*Ipomoea purpurea*	Campanilla morada	Herbaceo	1						1		
116	*Jacaratia mexicana*	Bonete	Arbóreo	1	1					2		
117	*Jatropha curcas*	Piñoncillo	Arbóreo	1						1		
118	*Laguncularia racemosa*	Mangle blanco	Arbóreo				1			1	Amenazada (A)	
119	*Lasiacis divaricata*	Otatillo	Arbustivo	1						1		
120	*Lasiacis nigra*	Pasto bolita	Herbaceo	1						1		
121	*Lasiacis procerrima*	Carricillo	Herbaceo	1						1		
122	*Lasianthaea fruticosa*	Vara san josé	Arbustivo	1						1		
123	*Leucaena microcarpa*	Guajillo	Arbóreo	1						1		
124	*Licania arborea*	Cuirindo	Arbóreo		1					1	Amenazada (A)	
125	*Lonchocarpus constrictus*	Garrapato	Arbóreo	1	1					2		
126	*Lonchocarpus eriocarinalis*	Cuero de indio	Arbóreo	1	1					2		
127	*Lonchocarpus sericeus*	Cuero de vaca	Arbóreo	1	1					2		
128	*Luehea candida*	Algodoncillo	Arbóreo	1						1		
129	*Lygodium venustum*	Helecho enredadera	Herbaceo	1						1		
130	*Lysiloma acapulcensis*	Tepehuaje	Arbóreo		1	1				2		
131	*Lysiloma divaricatum*	Tepemezquite	Arbóreo		1					1		
132	*Lysiloma microphyllum*	Tepemezquite	Arbóreo	1						1		
133	*Macroptilium atropurpureum*	Frijolillo	Herbaceo	1						1		
134	*Malvaviscus arboreus*	Obelisco de cerro	Arbustivo	1	1					2		
135	*Manihot aesculifolia*	Manitas	Arbóreo	1						1		
136	*Manihot chlorosticta*	Manihot	Arbustivo	1						1		
137	*Margaritaria nobilis*	Vidrillo	Arbóreo	1	1					2		
138	*Meliosma dentata*	Aguacatillo	Arbóreo		1					1		
139	*Miconia xalapensis*	Mora	Arbustivo		1	1				2		
140	*Mimosa albida*	Sierrilla	Otras especies	1						1		
141	*Mimosa pudica*	Sierrilla	Herbaceo	1						1		
142	*Momordica charantia*	Pepinillo amarillo	Herbaceo	1						1		
143	*Mucuna pruriens*	Pica pica	Herbaceo	1						1		
144	*Muntingia calabura*	Juanito	Arbóreo	1						1		
145	*Myroxylon horridum*	Huizcoron	Arbóreo	1						1		
146	*Nectandra salicifolia*	Aguacatillo	Arbóreo	1						1		
147	*Neltuma juliflora*	Mezquite	Arboreo						1	1		
148	*Oplismenus compositus*	Pasto huevero	Herbaceo	1	1	1				3		
149	*Pachycereus pecten-aboriginum*	Cactus organo pitayo	Otras especies	1						1		Apendice II
150	*Panicum maximum*	Pasto tanzania	Herbaceo	1		1				2		
151	*Paullinia clavigera*	Bejuco Costillon	Otras especies		1					1		
152	*Paullinia sessiliflora*	Bejuco Costillon	Otras especies	1						1		
153	*Pectis multiflosculosa*	Verdolaga	herbáceo						1	1		
154	*Petiveria alliacea*	Arriscale patras	Herbaceo		1					1		
155	*Philodendron hederaceum*	Colomo trepador	Herbaceo		1					1		
156	*Phyllanthus elsiae*	Carne de gallina	Arbóreo				1			1		
157	*Phyllanthus mocinianus*	Oreja de raton	Arbóreo	1						1		
158	*Pilosocereus purpusii*	Pitayo serpetinum	Otras especies	1						1		Apendice II
159	*Piper hispidum*	Piper lanceolado	Arbustivo	1	1	1				3		
160	*Piper peltatum*	Piper acorazonado	Arbustivo		1	1				2		
161	*Piptadenia flava*	Sierrilla arborea	Arbóreo	1						1		
162	*Pisonia aculeata*	Chorumo colmillo de puerco	Arbustivo	1	1					2		
163	*Pithecellobium dulce*	Guamuchil	Arbóreo	1						1		
164	*Pithecellobium lanceolatum*	Timuchil	Arbóreo	1			1			2		
165	*Platymiscium lasiocarpum*	Granadillo	Arbóreo	1	1					2	Peligro de extinsion (P)	
166	*Plumeria rubra*	Sacaloxochil	Arbóreo	1						1		
167	*Portulaca oleracea*	Verdolaga	Herbaceo	1						1		
168	*Psidium sartorianum*	Guayabillo	Arbóreo	1						1		
169	*Quercus acutifolia*	Encino rojo	Arboreo			1				1		
170	*Quercus magnoliifolia*	Encino Amarillo	Arboreo			1				1		
171	*Quercus obtusata*	Encino blanco	Arboreo			1				1		
172	*Randia armata*	Crucillo	Arbustivo	1	1	1				3		
173	*Rauvolfia tetraphylla*	Sarna de perro	Arbustivo	1						1		
174	*Recchia mexicana*	Manzanito	Arbóreo	1						1		
175	*Rhipidocladum racemiflorum*	Carricillo otatillo de cerro	Arbustivo	1	1	1				3		
176	*Rhizophora mangle*	Mangle rojo	Arbóreo				1			1	Amenazada (A)	
177	*Rhynchosia precatoria*	Frijolillo	Herbaceo			1				1		
178	*Roldana chapalensis*	Rondala	Arbustivo	1						1		
179	*Roseodendron donnell-smithii*	Primavera	Arbóreo	1	1					2		
180	*Sapindus saponaria*	Bolitario	Arbóreo	1						1		
181	*Sapium macrocarpum*	Higuerilla brava	Arbóreo	1	1	1				3	Amenazada (A)	
182	*Scaevola plumieri*	Bejuco costero	Otras especies	1						1		
183	*Senna atomaria*	Vainillo	Arbóreo		1					1		
184	*Senna obtusifolia*	Retama	Arbustivo		1	1				2		
185	*Serjania brachycarpa*	Bejuco serjania	Otras especies	1	1	1				3		

186	*Sesuvium portulacastrum*	Verdolaga de playa	Herbaceo					1		1		
187	*Sicyos barbatus*	Chayotillo tronador	Herbaceo	1						1		
188	*Sida glabra*	Guinar escobero	Herbaceo	1	1	1				3		
189	*Sideroxylon capiri*	Capire	Arbóreo	1						1	Amenazada (A)	
190	*Sideroxylon persimile*	Huizilacate negro	Arbóreo	1						1		
191	*Smilax spinosa*	Bejuco alambre	Otras especies	1	1					2		
192	*Spondia purpurea*	Ciruelo	Arbóreo	1	1					2		
193	*Sporobolus pyramidatus*	Pasto salado	herbáceo						1	1		
194	*Sporobolus virginicus*	Pasto amarillo	Herbaceo	1				1		2		
195	*Stegnosperma cubense*	Bejuco de arena	Otras especies						1	1		
196	*Stemmadenia tomentosa*	San antonio	Arbóreo	1	1					2		
197	*Struthanthus interruptus*	Mal ojo	Otras especies						1	1		
198	*Styrax argenteus var. ramirezii*	Azajar	Arbóreo	1	1					2		
199	*Tabebuia chrysantha*	Mapilla	Arbóreo	1						1	Amenazada (A)	Apendice II
200	*Tabebuia rosea*	Rosa morada	Arbóreo		1	1				2		
201	*Thouinia serrata*	Huesillo de cerro	Arbóreo	1	1					2		
202	*Tillandsia intermedia*	Tillandicia	Otras especies	1						1		
203	*Tournefortia mutabilis*	Huele de noche	Arbustivo			1				1		
204	*Tribulus cistoides*	Abrojo pegajoso	Herbaceo	1	1					2		
205	*Trichilia americana*	Cola de zorra	Arbóreo	1	1	1				3		
206	*Triumfetta semitriloba*	Abrojo	Arbustivo			1				1		
207	*Trophis racemosa*	Falso ramon	Arbóreo	1						1		
208	*Urera caracasana*	Quemadora carascana	Arbustivo	1	1					2		
209	*Verbesina oligantha*	Vara blanca	Arbustivo	1	1	1				3		
210	*Zamia paucijuga*	samia de colima	Otras especies			1				1	Protección especial (Pr)	Apendice II
211	*Zanthoxylum arborescens*	Zorrillo	Arbóreo	1						1

Listado de especies ícticas de la Laguna de Cuyutlán de 2024 a 2026, de acuerdo con la modificación del anexo normativo III de la NOM-059-SEMARNAT-2010.

Familia	Género	Especie	Categoría intraespecífica	Nombre intraespecífico	Autor	Sinonimia	Nombres comunes	Distribución	Categoría de riesgo
Achiridae	*Achirus*	*klunzingeri*			Steindachner, 1879.		Lenguado, suela plomiza, lenguado redondo plomizo, suela guardaboya	La parte central de México a Ecuador; las Islas Galápagos.	N/A
Carangidae	*Caranx*	*caninus*			Günther, 1867		Jurel toro	El Sur de California al Golfo de California a Perú y la Islas de Revillagigedo, las Galápagos, del Coco y Malpelo.	N/A
	Caranx	*caballus*			Günther, 1868.		Cocinero, jurel bonito, jurel cojinua	Sur de California a Chile, y todas las islas oceánicas; ocasionalmente registrado en abundancia en Hawái, pero no establecido allá.	N/A
	Caranx	*vinctus*			Jordan & Gilbert, 1882.		Chocho, jurel rayado, jurel platanito.	Del sur de California a los 2/3 inferiores del Golfo de California	N/A

								central y Perú y Malpelo.	
	Choroscombrus	*orqueta*			Jordan & Gilbert, 1883		Catalina, horqueta del pacifico, orqueta, jurel pardo, jurel citarina	Es un género tropical restringido al Pacífico Oriental (una especie endémica) y al Atlántico (una especie endémica).	N/A
	Selar	crumenophthalmus			Blonch, 1793		Ojotón, chícharro, jiguagua, sábalo de ojo grande	Mares tropicales y subtropicales; la parte central de la Baja y el Golfo de California a Ecuador y las Islas Oceánicas.	N/A
Centropomidae	*Centropomus*	*robalito*			Jordan & Gilbert, 1882		Constantino, robalo aletas amarillas, robalito	La parte sur del Golfo de California a Ecuador.	N/A
Centropomidae	*Centropomus*	*viridis*			Lockington, 1877		Róbalo plateado, róbalo blanco	Baja California Sur y el Golfo de California Central	N/A

								al sur de Ecuador y las Galápagos.	
Chaenidae	*Chanos*	*chanos*			Forsskål, 1775		Sábalo, sabalote, chano.	Una especie del Indo-Pacífico; el sur de California al Golfo de California a Perú.	N/A
Dorosomatidae	*Ophistonema*	*bulleri*			Regan, 1904		Sardina crinuda azul, machuelo hebra fina, sadrina gallera fina.	El Golfo de California al norte de Perú.	N/A
	Ophistonema	*libertate*			Günther, 1867		Sardina crinuda, sardina gallera común, sardina gallera pecosa, machuelo hebra del Pacífico, arenque de hebra común.	El sur de California a Chile.	N/A
Elopidae	*Elops*	*affinis*			Regan, 1909		Chile, machete del Pacífio, pez torpedo	Sur de California al norte de Perú.	N/A
Engraulidae	*Anchovia*	*macrolepidota*			Kner, 1863.		Huesuda, anchoveta escamuda, anchoa escamas grandes.	El Golfo de California al norte de Perú.	N/A

Gerreidae	*Diapterus*	*brevirostris*			Sauvage, 1879		Malacapa, mojarra aletas amarillas, palmito aleta amarilla	El sur de Baja y los 2/3 inferiores del Golfo de California a Perú, las Galápagos e Islas de Revillagigedo.	N/A
	Gerres	*simillumus*			Gill, 1862		Mojarra rayada, mojarra amarilla, palmito rayado del Pacífico, palmito blanco del Pacífico	El sur de Baja California y los 2/3 inferiores del Golfo de California a Perú y las Galápagos.	N/A
Haemullidae	*Haemulopsis*	*elongatus*			Steindachner, 1879.		Ronco alargado, ronco trompudo.	El sur de Baja y los ¾ inferiores del Golfo de California a Panamá.	N/A
Lutjanidae	*Lutjanus*	*argentiventris*			Peters, 1869		Alazán, pargo amarillo.	El sur de California al Golfo de California y a Perú, incluyendo todas las islas oceánicas menos Clipperton.	N/A
Mugilidae	*Mugil*	*cephalus*			Linnaeus, 1758		Lisa cabezuda, Lisa común, lisa pardete, lisa rayada	Sur de California al Golfo de	N/A

								California a Perú y las Galápagos.	
	Mugil	*setosus*			Gilbert, 1892		Lisa liseta	Baja California y el Golfo de California hasta Perú, las Islas Revillagigedo, Isla del Coco y las Galápagos.	N/A
Scianidae	*Larimus*	*acclivis*			Jordan & Bristol, 1898.		Boquinete, corvina ñata rayada	Baja California Sur y el este del Golfo de California al norte de Perú.	N/A
Scombridae	*Euthynnus*	*lineatus*			Kishinouye, 1920		Barrilete negro	California a la mitad inferior del Golfo de California a Perú, incluyendo todas las islas oceánicas; especímenes aislados en las Islas Hawaianas.	N/A
Portunidae	*Callinectes*	*arcuatus*			Ordway, 1863		Jaiba azul del Pacífico, jaiba cuata	Se encuentra por todo el Pacífico	N/A

								mexicano, desde Baja California hasta Chiapas.	

LISTADO DE ESPECIES IDENTIFICADAS EN EL MUESTREO EN EL SAR

No.	Nombre Cientifico	Nombre Común	Estrato	SBC	SMS	BQ	M	VHH	DC	Tipos	Categoría	CITES
1	*Abutilon trisulcatum*	Acapan	Herbaceo	1						1		
2	*Acacia cochliacantha*	Espino blanco	Arbóreo	1						1		
3	*Acacia farnesiana*	Huizache	Arbustivo	1						1		
4	*Acacia glomerosa*	Espino monte	Arbóreo	1						1		
5	*Acacia hindsii*	Huizcolote	Arbóreo	1						1		
6	*Acacia macilenta*	Chacalcahuil	Arbóreo	1						1		
7	*Acacia tenuifolia*	Aguilillo	Arbustivo	1						1		
8	*Acalypha mexicana*	Cancerina	Herbaceo	1					1	2		
9	*Acanthocereus tetragonus*	Tazajo	Otras especies	1	1					2		Apendice II
10	*Adenopodia gymnantha*	Bejuco sierrilla	Otras especies	1	1					2		
11	*Adiantum concinnum*	Helecho bipinado	Herbaceo		1					1		
12	*Adiantum tricholepis*	Helecho dentado	Herbaceo		1	1				2		
13	*Aechmea bracteata*	Bromelia aserrada	Otras especies			1				1		
14	*Agonandra racemosa*	Chilcahuite	Arbóreo		1					1		
15	*Albizia occidentalis*	Parotilla china	Arbóreo	1	1					2	Amenazada (A)	
16	*Albizia tomentosa*	Parotilla Morada	Arbóreo	1						1		
17	*Alstonia longifolia*	Frijolillo doble	Arbóreo	1						1		
18	*Ambrosia psilostachya*	Hierba amargosilla	Herbaceo	1	1	1				3		
19	*Ampelocissus acapulcensis*	Uva cimarrona	Otras especies	1						1		
20	*Amphilophium crucigerum*	Bejuco corona	Otras especies	1	1					2		
21	*Amphipterygium adstringens*	Cuachalalate	Arbóreo	1						1		
22	*Andira inermis*	Almendro de río	Arbóreo		1					1		
23	*Annona purpurea*	Cabeza de negro	Arbóreo		1					1		
24	*Antigonon flavescens*	Zarzal morado	Herbaceo	1	1					2		
25	*Aphananthe monoica*	Chiillo / Palo barranco	Arbóreo	1	1					2		
26	*Aphelandra linearíloba*	Afelandras	Herbaceo	1						1		
27	*Aphelandra scabra*	Cola de gallo	Arbustivo	1	1					2		
28	*Apoplanesia paniculata*	Llora sangre de cerro	Arbóreo	1						1		
29	*Ardisia compressa*	Chico corriozo	Arbustivo		1					1		
30	*Aristolochia taliscana*	Bejuco corchozo	Otras especies	1	1					2		
31	*Astraea lobata*	Manzanita	herbáceo						1	1		
32	*Astronium graveolens*	Culebro	Arbóreo	1	1					2	Amenazada (A)	
33	*Attalea cohune*	Palma de cayaco	Otras especies		1					1	Protección especial	
34	*Avicennia germinans*	Mangle prieto	Arbóreo				1			1	Amenazada (A)	
35	*Ayenia aculeata*	Sierrilla cuadrada	Arbustivo	1						1		
36	*Batis maritima*	Saladilla	Herbaceo					1		1		
37	*Bauhinia divaricata*	Pata de cabra	Arbustivo	1						1		
38	*Blechum pyramidatum*	Cancerillo	Herbaceo			1				1		
39	*Bonellia macrocarpa*	Pica pendejos	Arbustivo	1						1		
40	*Bravaisia integerrima*	Mangle de cerro	Arbóreo	1						1	Amenazada (A)	
41	*Brosimum alicastrum*	Mojo	Arbóreo	1	1					2		
42	*Bursera copallifera*	Copal	Arbóreo	1		1				2		
43	*Bursera grandifolia*	Papelillo Verde	Arbóreo	1	1					2		
44	*Bursera sarcopoda*	Tecomaca	Arbóreo	1						1		
45	*Bursera simaruba*	Papelillo rojo	Arbóreo	1	1					2		
46	*Caesalpinia pulcherrima*	Tabachincillo	Arbustivo	1						1		
47	*Calathea atropurpurea*	Tacuachin	Herbaceo	1						1		
48	*Calliandra caeciliae*	Vara de angel	Arbustivo			1				1		
49	*Calophyllum brasiliense*	Palo maría	Arbóreo		1					1	Amenazada (A)	
50	*Canavalia rosea*	*Canavalia*	herbáceo						1	1		
51	*Cascabela ovata*	Ayoyote	Arbóreo	1						1		
52	*Casearia nitida*	Chamizo	Arbóreo	1	1					2		
53	*Casimiroa edulis*	Zapotillo	Arbóreo	1						1		
54	*Cecropia obtusifolia*	Trompetero	Arbóreo		1					1		
55	*Cedrela odorata*	Cedro rojo	Arbóreo		1	1				2	Protección especial (Pr)	Apendice II
56	*Ceiba aesculifolia*	Pochote	Arbóreo	1						1		
57	*Celtis iguanaea*	Granjeno	Arbustivo	1						1		
58	*Cenostigma eriostachys*	Iguanero de la costa	Arbóreo	1	1					2		
59	*Chloroleucon mangense*	Guayabillo borcelano	Arbóreo	1	1					2		
60	*Cissus microcarpa*	Bejuco tripa de vaca	Otras especies	1						1		
61	*Cissus verticillata*	Bejuco tripa de vaca	Otras especies	1		1				2		
62	*Clethra hartwegii*	Cucharo	Arbóreo		1					1		
63	*Cnidoscolus multilobus*	Quemadora palmaeda	Arbustivo	1						1		
64	*Cochlospermum vitifolium*	Panicua	Arbóreo	1		1				2		
65	*Cocos nucifera*	Palma de coco	Otras especies	1						1		
66	*Combretum fruticosum*	Bejuco corona	Otras especies	1						1		
67	*Commelina diffusa*	Tripa de Pollo	Herbaceo	1		1				2		
68	*Commicarpus scandens*	Bellesa del pacifico pegajosila	Arbustivo		1					1		
69	*Comocladia engleriana*	Hincha huevos	Arbóreo	1						1		
70	*Conium maculatum*	Cilantrillo	Herbaceo			1				1		
71	*Conocarpus erectus*	Mangle botoncillo	Arbóreo				1			1	Amenazada (A)	
72	*Cordia alliodora*	Botoncillo	Arbóreo	1	1					2		
73	*Cordia dentata*	Tamborcillo	Arbóreo	1						1		
74	*Cordia elaeagnoides*	Barcino	Arbóreo	1	1					2		
75	*Cordia gerascanthus*	Nance ogelato	Arbóreo	1						1		
76	*Costus pulverulentus*	Caña de indio	Herbaceo	1						1		
77	*Coulteria platyloba*	Coral	Arbóreo	1						1		
78	*Crataeva tapia*	Bulillo	Arbóreo	1						1		
79	*Crinum erubescens*	Lirio del valle	Herbaceo	1						1		
80	*Crotalaria micans*	Sonajilla lanceolada	Arbustivo	1						1		
81	*Croton suberosus*	Mata corchosa	Arbustivo	1						1		
82	*Cryosophila nana*	Palma escobera	Otras especies			1				1	Amenazada (A)	
83	*Cucurbita moschata*	Calabacilla	Herbaceo	1						1		
84	*Cupania dentata*	Palo acanalado	Arbóreo		1					1		
85	*Dendropanax arboreus*	Macarmina	Arbóreo		1					1		
86	*Desmodium Incanum*	Frijolillo arbustivo	Arbustivo			1				1		
87	*Dicliptera resupinata*	Maleza de las lomas	Herbaceo	1	1					2		
88	*Dioscorea mexicana*	Camote de cerro	Herbaceo	1						1		
89	*Diphysa americana*	Hormiguillo	Arbóreo	1						1		
90	*Elytraria imbricata*	Cordoncillo	Herbaceo	1	1	1				3		
91	*Enterolobium cyclocarpum*	Parota	Arbóreo	1	1	1				3		

92	*Erythrina americana*	Colorin	Arbóreo	1						1		
93	*Eupatorium glabratum*	Arbusto de la paloma	Arbustivo	1						1		
94	*Ficus cotinifolia*	Tescalama	Arbóreo		1					1		
95	*Ficus maxima*	Higuera blanca	Arbóreo		1					1		
96	*Ficus velutina*	Zalate	Arbóreo	1						1		
97	*Forchhammeria pallida*	Olivillo	Arbóreo	1	1					2		
98	*Galinsoga parviflora*	Manzanilla silvestre	Herbaceo		1	1				2		
99	*Gliricidia sepium*	Cacanahual	Arbóreo	1						1		
100	*Gronovia scandens*	Arroz de leche	Herbaceo	1						1		
101	*Guardiola tulocarpus*	Vara prieta	Arbustivo	1						1		
102	*Guazuma ulmifolia*	Guasima	Arbóreo	1	1					2		
103	*Guettarda elliptica*	Limoncillo tronco de guayabo	Arbustivo	1	1					2		
104	*Gyrocarpus jatrophifolius*	Rebelero	Arbóreo	1	1					2		
105	*Heliocarpus terebinthinaceus*	Majahua	Arbóreo	1	1	1				3		
106	*Hintonia latiflora*	Trepa chuy	Arbóreo	1						1		
107	*Hura polyandra*	Habillo	Arbóreo	1	1					2		
108	*Hyperbaena ilicifolia*	Gorda dura	Arbustivo	1						1		
109	*Hyptis suaveolens*	Chan	Herbaceo	1		1				2		
110	*Indigofera densiflora*	Frijolillo vaina	Herbaceo	1						1		
111	*Indigofera suffruticosa*	Senna arbustiva añil	Arbustivo	1						1		
112	*Inga eriocarpa*	Cuil	Arbóreo		1					1		
113	*Ipomoea carnea*	Amapola rosa	Herbaceo	1						1		
114	*Ipomoea murucoides*	Osote	Arbóreo	1						1		
115	*Ipomoea purpurea*	Campanilla morada	Herbaceo	1						1		
116	*Jacaratia mexicana*	Bonete	Arbóreo	1	1					2		
117	*Jatropha curcas*	Piñoncillo	Arbóreo	1						1		
118	*Laguncularia racemosa*	Mangle blanco	Arbóreo				1			1	Amenazada (A)	
119	*Lasiacis divaricata*	Otatillo	Arbustivo	1						1		
120	*Lasiacis nigra*	Pasto bolita	Herbaceo	1						1		
121	*Lasiacis procerrima*	Carricillo	Herbaceo	1						1		
122	*Lasianthaea fruticosa*	Vara san josé	Arbustivo	1						1		
123	*Leucaena microcarpa*	Guajillo	Arbóreo	1						1		
124	*Licania arborea*	Cuirindo	Arbóreo		1					1	Amenazada (A)	
125	*Lonchocarpus constrictus*	Garrapato	Arbóreo	1	1					2		
126	*Lonchocarpus eriocarinalis*	Cuero de indio	Arbóreo	1	1					2		
127	*Lonchocarpus sericeus*	Cuero de vaca	Arbóreo	1	1					2		
128	*Luehea candida*	Algodoncillo	Arbóreo	1						1		
129	*Lygodium venustum*	Helecho enredadera	Herbaceo	1						1		
130	*Lysiloma acapulcensis*	Tepehuaje	Arbóreo		1	1				2		
131	*Lysiloma divaricatum*	Tepemezquite	Arbóreo		1					1		
132	*Lysiloma microphyllum*	Tepemezquite	Arbóreo	1						1		
133	*Macroptilium atropurpureum*	Frijolillo	Herbaceo	1						1		
134	*Malvaviscus arboreus*	Obelisco de cerro	Arbustivo	1	1					2		
135	*Manihot aesculifolia*	Manitas	Arbóreo	1						1		
136	*Manihot chlorosticta*	Manihot	Arbustivo	1						1		
137	*Margaritaria nobilis*	Vidrillo	Arbóreo	1	1					2		
138	*Meliosma dentata*	Aguacatillo	Arbóreo		1					1		
139	*Miconia xalapensis*	Mora	Arbustivo		1	1				2		
140	*Mimosa albida*	Sierrilla	Otras especies	1						1		
141	*Mimosa pudica*	Sierrilla	Herbaceo	1						1		
142	*Momordica charantia*	Pepinillo amarillo	Herbaceo	1						1		
143	*Mucuna pruriens*	Pica pica	Herbaceo	1						1		
144	*Muntingia calabura*	Juanito	Arbóreo	1						1		
145	*Myroxylon horridum*	Huizcoron	Arbóreo	1						1		
146	*Nectandra salicifolia*	Aguacatillo	Arbóreo	1						1		
147	*Neltuma juliflora*	Mezquite	Arboreo						1	1		
148	*Oplismenus compositus*	Pasto huevero	Herbaceo	1	1	1				3		
149	*Pachycereus pecten-aboriginum*	Cactus organo pitayo	Otras especies	1						1		Apendice II
150	*Panicum maximum*	Pasto tanzania	Herbaceo	1		1				2		
151	*Paullinia clavigera*	Bejuco Costillon	Otras especies		1					1		
152	*Paullinia sessiliflora*	Bejuco Costillon	Otras especies	1						1		
153	*Pectis multiflosculosa*	Verdolaga	herbáceo						1	1		
154	*Petiveria alliacea*	Arriscale patras	Herbaceo		1					1		
155	*Philodendron hederaceum*	Colomo trepador	Herbaceo		1					1		
156	*Phyllanthus elsiae*	Carne de gallina	Arbóreo				1			1		
157	*Phyllanthus mocinianus*	Oreja de raton	Arbóreo	1						1		
158	*Pilosocereus purpusii*	Pitayo serpetinum	Otras especies	1						1		Apendice II
159	*Piper hispidum*	Piper lanceolado	Arbustivo	1	1	1				3		
160	*Piper peltatum*	Piper acorazonado	Arbustivo		1	1				2		
161	*Piptadenia flava*	Sierrilla arborea	Arbóreo	1						1		
162	*Pisonia aculeata*	Chorumo colmillo de puerco	Arbustivo	1	1					2		
163	*Pithecellobium dulce*	Guamuchil	Arbóreo	1						1		
164	*Pithecellobium lanceolatum*	Timuchil	Arbóreo	1			1			2		
165	*Platymiscium lasiocarpum*	Granadillo	Arbóreo	1	1					2	Peligro de extinsion (P)	
166	*Plumeria rubra*	Sacaloxochil	Arbóreo	1						1		
167	*Portulaca oleracea*	Verdolaga	Herbaceo	1						1		
168	*Psidium sartorianum*	Guayabillo	Arbóreo	1						1		
169	*Quercus acutifolia*	Encino rojo	Arboreo			1				1		
170	*Quercus magnoliifolia*	Encino Amarillo	Arboreo			1				1		
171	*Quercus obtusata*	Encino blanco	Arboreo			1				1		
172	*Randia armata*	Crucillo	Arbustivo	1	1	1				3		
173	*Rauvolfia tetraphylla*	Sarna de perro	Arbustivo	1						1		
174	*Recchia mexicana*	Manzanito	Arbóreo	1						1		
175	*Rhipidocladum racemiflorum*	Carricillo otatillo de cerro	Arbustivo	1	1	1				3		
176	*Rhizophora mangle*	Mangle rojo	Arbóreo				1			1	Amenazada (A)	
177	*Rhynchosia precatoria*	Frijolillo	Herbaceo			1				1		
178	*Roldana chapalensis*	Rondala	Arbustivo	1						1		
179	*Roseodendron donnell-smithii*	Primavera	Arbóreo	1	1					2		
180	*Sapindus saponaria*	Bolitario	Arbóreo	1						1		
181	*Sapium macrocarpum*	Higuerilla brava	Arbóreo	1	1	1				3	Amenazada (A)	
182	*Scaevola plumieri*	Bejuco costero	Otras especies	1						1		
183	*Senna atomaria*	Vainillo	Arbóreo		1					1		
184	*Senna obtusifolia*	Retama	Arbustivo		1	1				2		
185	*Serjania brachycarpa*	Bejuco serjania	Otras especies	1	1	1				3		

186	*Sesuvium portulacastrum*	Verdolaga de playa	Herbaceo					1		1		
187	*Sicyos barbatus*	Chayotillo tronador	Herbaceo	1						1		
188	*Sida glabra*	Guinar escobero	Herbaceo	1	1	1				3		
189	*Sideroxylon capiri*	Capire	Arbóreo	1						1	Amenazada (A)	
190	*Sideroxylon persimile*	Huizilacate negro	Arbóreo	1						1		
191	*Smilax spinosa*	Bejuco alambre	Otras especies	1	1					2		
192	*Spondia purpurea*	Ciruelo	Arbóreo	1	1					2		
193	*Sporobolus pyramidatus*	Pasto salado	herbáceo						1	1		
194	*Sporobolus virginicus*	Pasto amarillo	Herbaceo	1				1		2		
195	*Stegnosperma cubense*	Bejuco de arena	Otras especies						1	1		
196	*Stemmadenia tomentosa*	San antonio	Arbóreo	1	1					2		
197	*Struthanthus interruptus*	Mal ojo	Otras especies						1	1		
198	*Styrax argenteus var. ramirezii*	Azajar	Arbóreo	1	1					2		
199	*Tabebuia chrysantha*	Mapilla	Arbóreo	1						1	Amenazada (A)	Apendice II
200	*Tabebuia rosea*	Rosa morada	Arbóreo		1	1				2		
201	*Thouinia serrata*	Huesillo de cerro	Arbóreo	1	1					2		
202	*Tillandsia intermedia*	Tillandicia	Otras especies	1						1		
203	*Tournefortia mutabilis*	Huele de noche	Arbustivo			1				1		
204	*Tribulus cistoides*	Abrojo pegajoso	Herbaceo	1	1					2		
205	*Trichilia americana*	Cola de zorra	Arbóreo	1	1	1				3		
206	*Triumfetta semitriloba*	Abrojo	Arbustivo			1				1		
207	*Trophis racemosa*	Falso ramon	Arbóreo	1						1		
208	*Urera caracasana*	Quemadora carascana	Arbustivo	1	1					2		
209	*Verbesina oligantha*	Vara blanca	Arbustivo	1	1	1				3		
210	*Zamia paucijuga*	samia de colima	Otras especies			1				1	Protección especial (Pr)	Apendice II
211	*Zanthoxylum arborescens*	Zorrillo	Arbóreo	1						1

DIRECTRICES REVISADAS PARA REDUCIR EL RUIDO SUBMARINO RADIADO DEBIDO AL TRANSPORTE MARÍTIMO CON EL FIN DE ABORDAR SUS EFECTOS ADVERSOS EN LA FAUNA MARINA

1 El Comité de Protección del Medio Marino, en su 66º periodo de sesiones (31 de marzo a 4 de abril de 2014), con objeto de facilitar orientaciones sobre la reducción del ruido submarino debido al transporte marítimo comercial, y siguiendo la recomendación formulada por el Subcomité de Proyecto y Equipo del Buque (Subcomité DE) en su 57º periodo de sesiones, aprobó las "Directrices para reducir el ruido submarino debido al transporte marítimo comercial y sus efectos adversos en la fauna marina" (las Directrices).

2 El Comité de Protección del Medio Marino, en su 80º periodo de sesiones (3 a 7 de julio de 2023), tras una revisión amplia de las Directrices realizada por el Subcomité de Proyecto y Construcción del Buque (Subcomité SDC) en su 9º periodo de sesiones (23 a 27 de enero de 2023), con miras a aumentar la concienciación, la asimilación y la implantación, aprobó las "Directrices revisadas adjuntas para reducir el ruido submarino radiado debido al transporte marítimo con el fin de abordar sus efectos adversos en la fauna marina" (Directrices revisadas).

3 Se invita a los Estados Miembros a que utilicen las directrices revisadas adjuntas con el fin de reducir el ruido submarino radiado procedente de los buques y las pongan en conocimiento de todas las partes interesadas, en particular los proyectistas de buques y equipos, los constructores, propietarios y armadores de buques, las sociedades de clasificación, los proveedores, los fabricantes y otras partes interesadas.

4 Se invita también a los Estados Miembros y a las organizaciones internacionales a que presenten al Comité de Protección del Medio Marino, en relación con el punto del orden del día titulado "Otros asuntos", información, observaciones y recomendaciones basadas en la experiencia práctica adquirida mediante la aplicación de las Directrices revisadas.

5 Las presentes directrices revisadas entrarán en vigor el 1 de octubre de 2023.

6 Esta circular revoca la circular MEPC.1/Circ.833.

***

ANEXO

DIRECTRICES REVISADAS PARA REDUCIR EL RUIDO SUBMARINO RADIADO DEBIDO AL TRANSPORTE MARÍTIMO CON EL FIN DE ABORDAR SUS EFECTOS ADVERSOS EN LA FAUNA MARINA

1 PREÁMBULO

1.1 El transporte marítimo comercial es una de las fuentes principales del ruido submarino radiado, con sus consiguientes efectos adversos en funciones críticas para la vida de una amplia gama de especies de la fauna marina, incluidos mamíferos marinos, peces e invertebrados, de los que un gran número de comunidades indígenas costeras dependen para su alimentación, sustento y cultura.

1.2 La mitigación eficaz de las repercusiones del ruido submarino radiado causado por los buques en la fauna marina requiere la colaboración internacional y la adopción de medidas a varios niveles, con la participación de diversas partes interesadas, entre las que se encuentran la gente de mar, los proyectistas, los constructores, propietarios y armadores de buques, las autoridades marítimas, los proveedores, los fabricantes y las sociedades de clasificación. Los Estados Miembros desempeñan también un papel importante a la hora de fijar expectativas en cuanto a los objetivos de reducción del ruido y establecer mecanismos y programas a través de los cuales puedan llevarse a cabo los esfuerzos de reducción del ruido.

1.3 El sonido es el principal mecanismo sensorial utilizado por la fauna acuática para interaccionar socialmente, reproducirse, desplazarse en el agua y detectar obstáculos, presas, depredadores y otros peligros. Las fuentes de ruido principales de los buques se solapan con las gamas de audición y el uso del sonido de distintas especies. En función de la especie, las repercusiones documentadas del ruido submarino radiado en los mamíferos marinos, los peces y los invertebrados incluyen alteraciones del desarrollo, malestar corporal, aumento de la depredación, disminución de la supervivencia de las crías, peor alimentación, fragmentación del ADN, cambios de comportamiento, problemas de enmascaramiento y respuestas fisiológicas. Aunque las repercusiones del ruido del transporte marítimo se han evaluado teniendo en cuenta las características ambientales de las distintas regiones y la sensibilidad al ruido de las diferentes especies a partir de observaciones sobre el terreno, experimentos de laboratorio, enfoques de modelización y conocimientos indígenas, la obtención de más datos sobre las repercusiones del ruido en especies de interés ecológico y comercial clave ayudará a informar a las partes interesadas.

1.4 Es importante que se reconozca que, tanto para los buques nuevos como para los existentes, la viabilidad técnica y la rentabilidad de las medidas de reducción del ruido submarino radiado, consideradas individualmente o en conjunto, dependerán en gran medida del proyecto, los parámetros operacionales y las prescripciones pertinentes para un buque determinado. Una estrategia eficaz para reducir el ruido submarino radiado debería ser un proceso que incluya, en la medida de lo posible, la fase de proyecto, la determinación de referencias para las mediciones del ruido submarino radiado (previstas o reales), la elaboración de objetivos relativos al ruido submarino radiado y la implantación, la vigilancia y la evaluación de las medidas técnicas y operacionales para alcanzar dichos objetivos. Deberían examinarse detenidamente las interacciones entre la implantación de las medidas de reducción del ruido submarino radiado y otros objetivos, por ejemplo, la eficiencia energética, la reducción de incrustaciones biológicas y la seguridad de los buques, así como las contribuciones resultantes.

2 ÁMBITO DE APLICACIÓN

2.1 Las presentes directrices pueden aplicarse a cualquier buque, teniendo en cuenta su proyecto, construcción, modificaciones y funcionamiento.

2.2 Las presentes directrices no tratan de la introducción de ruido debido a buques de guerra y buques auxiliares de la armada ni de la introducción deliberada de ruido para otros fines, como el sónar o el estudio de la actividad sísmica.

3 FINALIDAD

3.1 Las presentes directrices tienen por finalidad:

.1 ofrecer una visión general de los enfoques aplicables a los proyectistas, constructores y armadores de buques para reducir el ruido submarino radiado de un buque determinado; y

.2 ayudar a las partes interesadas pertinentes a establecer mecanismos y programas que permitan reducir el ruido.

3.2 Dadas las complejidades asociadas con el proyecto y la construcción de buques, y los diversos enfoques para reducir el ruido submarino radiado generado por aquellos, las presentes directrices se centran en la determinación de los factores que más contribuyen al ruido submarino radiado generado por los buques y en un enfoque general que puedan adoptar los proyectistas, constructores, propietarios y armadores de buques. Dichos factores se asocian con las hélices, la forma del casco, las máquinas de a bordo, el flujo de la estela y los aspectos operacionales y de mantenimiento.

3.3 Las presentes directrices describen la planificación de la gestión de la reducción del ruido submarino radiado como una herramienta que puede aplicarse al funcionamiento, el proyecto, la construcción y la modificación de los buques, en la medida en que sea razonable y práctico.

3.4 Se alienta a los proyectistas de buques y equipos, los constructores, propietarios y armadores de buques, las autoridades marítimas, las sociedades de clasificación, los proveedores, los fabricantes y otras partes interesadas a que introduzcan y apliquen las presentes directrices a sus actividades específicas y a que sopesen cualquier otra tecnología y medida operacional no incluida en estas directrices que pueda ser más apropiada para aplicaciones específicas y haya demostrado su eficacia para reducir aún más el ruido submarino radiado.

3.5 La elaboración de soluciones tecnológicas para reducir el ruido submarino radiado y los conocimientos científicos en torno a las repercusiones de dicho ruido en la fauna marina seguirán evolucionando. Las presentes directrices se examinarán y actualizarán periódicamente para garantizar que las partes pertinentes dispongan de la mejor información posible para fundamentar los esfuerzos de reducción del ruido submarino radiado y tener en cuenta los vínculos con las medidas de cumplimiento de la eficiencia energética. Se alienta a los Estados Miembros y observadores a que transmitan la experiencia y la información recibida de, entre otros, los proyectistas de buques y equipos, los constructores y operadores de buques, las organizaciones científicas, la sociedad civil y las personas con conocimientos indígenas, a fin de mejorar y actualizar las presentes directrices.

4 DEFINICIONES

A efectos de las presentes directrices, se aplican las definiciones siguientes:

Ruido submarino radiado (URN) de referencia: nivel de la fuente del buque (y la profundidad de la fuente conexa) para condiciones operacionales típicas, que se desprende de las predicciones y ensayos iniciales o, preferiblemente, de mediciones normalizadas.

Cavitación: reducción de la presión ambiental por un medio estático o dinámico que puede deberse a la hélice u otros dispositivos y que causa la formación de burbujas en el líquido. La formación se refiere tanto a la creación de una nueva cavidad como a la expansión de una existente. Cuando estas burbujas se desplazan a regiones de mayor presión ambiental, se rompen y se convierten en la fuente principal de ruido de los buques con propulsión.

Velocidad de inicio de la cavitación: velocidad del buque a la que puede detectarse la cavitación (visual o acústicamente).

Buque existente: buque que no es un buque nuevo.

Gama auditiva: gama de frecuencias que puede detectar el oído o cualquier otro órgano sensorial de un animal.

Conocimientos indígenas: forma sistemática de pensamiento que se aplica a los fenómenos de los sistemas biológicos, físicos, culturales y espirituales. Incluye percepciones basadas en pruebas y adquiridas a través de experiencias directas y a largo plazo y de observaciones, lecciones y habilidades amplias y multigeneracionales. Se ha desarrollado a lo largo de milenios y sigue haciéndolo como parte de un proceso vivo que incluye los conocimientos que se adquieren en la actualidad y los que se adquirirán en el futuro, y se transmite de generación en generación. En virtud de esta definición, los conocimientos indígenas van más allá de las observaciones y los conocimientos ecológicos, y ofrecen una "forma del saber" singular.

Enmascaramiento: cuando el ruido interfiere en la detección y la percepción de otros sonidos importantes para la fauna marina. El enmascaramiento puede causar, entre otras cosas, una reducción o una pérdida de la capacidad de comunicación de las especies marinas.

Buque nuevo: buque cuyo contrato de construcción se adjudique, o, en ausencia de un contrato de construcción, cuya quilla se coloque, o cuya construcción se encuentre en una fase equivalente, en la fecha de entrada en vigor de las presentes directrices, o posteriormente.

Ruido de la hélice: aquel causado por fenómenos de flujo en la hélice cuando funciona en el campo de estela del casco del buque. El ruido de la hélice se compone del ruido de la hélice sin cavitación y del ruido de cavitación. Si se produce la cavitación, suele ser la fuente de ruido dominante.

Nivel de ruido radiado (RNL): se expresa como el nivel de presión acústica en decibelios. El nivel de ruido radiado es un nivel de fuente del buque suponiendo que este es una fuente acústica puntual. Se calcula multiplicando la distancia desde un punto de referencia del buque, D, por la presión acústica media cuadrática de campo lejano, PRMS(D), a esa distancia para un valor de referencia especificado.

Matemáticamente,

$$RNL = 20 \cdot log_{10}\left(\frac{P_{RMS}}{P_{REF}}\right) + 20 \cdot log_{10}\left(\frac{D}{D_{REF}}\right) dB$$

El valor de referencia para la presión (PREF) es igual a 1 micro-Pa. El valor de referencia para la distancia (DREF) es igual a 1 metro. En la norma ISO 17208-1:2016: *Underwater acoustics - Quantities and procedures for description and measurement of underwater sound from ships - Part 1: Requirements for precision measurements in deep water used for comparison purposes* figura una definición técnica completa.

Nivel de presión acústica: para el ruido submarino, 10 veces el logaritmo en base diez del cuadrado del cociente de la presión acústica submarina media cuadrática (P) entre la presión acústica de referencia de 1 micropascal, $SPL = 10 \cdot \log_{10}(P/P_{REF})^2$; donde PREF = 1 micropascal.

Ruido estructural: es la vibración en la estructura del buque que generará ruido cuando una superficie vibrante excite el medio circundante, es decir, cimientos, tuberías, otras máquinas acopladas o equipos auxiliares conectados. El ruido estructural suele medirse y cuantificarse midiendo las vibraciones.

Nivel de la fuente: para los niveles de fuente submarinos, véase la norma ISO 18405:2017 *(Underwater acoustics – Terminology).* En general, el nivel de la fuente se utiliza para cuantificar cuánto sonido (o vibración) genera un dispositivo (máquina u otra entidad, por ejemplo, un buque) a una distancia de referencia (convencionalmente a 1 m para la acústica submarina).

Nivel de ruido submarino radiado (URN): a efectos de las presentes directrices, el ruido causado por cualquier buque. El nivel de ruido submarino radiado se indicará en decibelios como nivel de presión acústica.

Soportes antivibratorios: elementos vibroelásticos (muelles de acero, caucho u otros sistemas) utilizados para aislar las vibraciones de las máquinas de la estructura del buque reduciendo la amplitud de la energía de vibración. También pueden utilizarse soportes antivibratorios para proteger el equipo de vibraciones perjudiciales procedentes del exterior del buque (por ejemplo, los impactos experimentados en condiciones meteorológicas adversas).

5 PLANIFICACIÓN DE LA GESTIÓN DEL RUIDO SUBMARINO RADIADO (URN)

5.1 La planificación de la gestión del ruido submarino radiado es un enfoque generalizado aplicable a los buques de conformidad con la sección 2 que incluye posibles estrategias para la reducción de dicho ruido en las fases de proyecto, construcción, funcionamiento y/o modificación.

5.2 Dadas las complejidades asociadas con el proyecto y la construcción de buques y los diversos enfoques para reducir el ruido submarino radiado, los propietarios y los proyectistas de buques deberían emprender la planificación de la gestión del ruido submarino radiado en las primeras fases de proyecto. Del mismo modo, la planificación de la gestión del ruido submarino radiado puede llevarse a cabo para los buques existentes en la medida en que sea razonable y factible.

5.3 La planificación de la gestión del ruido submarino radiado está destinada a ser una herramienta flexible que permita un enfoque personalizado, y puede incluir el establecimiento de una referencia (prevista o real) del ruido submarino radiado de un buque, la determinación de objetivos relativos a dicho ruido que deberían ser específicos y, cuando sea posible, cuantitativos, y la evaluación, por separado o en combinación, de diversos enfoques tecnológicos, operacionales y de mantenimiento para reducir el ruido submarino radiado. En el apéndice 3 figuran dos modelos de formulario con diversos niveles de detalle para guiar a los propietarios/proyectistas de los buques en este proceso.

5.4 A fin de apoyar una planificación eficaz de la gestión del ruido submarino radiado, diversas partes cuentan con las oportunidades siguientes:

.1 Propietarios de buques: elaborar y aplicar el plan de gestión del ruido submarino radiado, incluir las prescripciones sobre dicho ruido en las especificaciones de proyecto de los buques y mantener los buques conforme a dichas especificaciones.

.2 Proyectistas: proyectar los buques según lo definido en el plan operacional de sus propietarios para cumplir las prescripciones sobre el ruido submarino radiado.

.3 Constructores de buques: construir un buque que cumpla las especificaciones sobre el ruido submarino radiado.

.4 Operadores de buques: explotar el buque para cumplir los objetivos relativos al ruido submarino radiado y cualquier prescripción regional adicional a la que estén sujetos.

.5 Autoridades marítimas: adoptar medidas de apoyo que permitan la planificación de la gestión del ruido submarino radiado y la hagan avanzar, por ejemplo, apoyando el despliegue de herramientas para medir los niveles de ruido de los buques, respaldar la innovación y la adopción de tecnologías de reducción del ruido y comunicar información sobre el ruido submarino radiado.

.6 Sociedades de clasificación: ayudar a los propietarios/constructores de buques mediante predicciones, ensayos, anotaciones pertinentes sobre el ruido submarino radiado, certificación, etc., en la medida de lo razonable y factible.

.7 Proveedores y fabricantes: proporcionar equipos a los constructores y propietarios de buques que ayuden a que el buque cumpla las especificaciones sobre el ruido submarino radiado.

6 ENFOQUES PARA LA REDUCCIÓN DEL RUIDO SUBMARINO RADIADO

6.1 Las hélices, la forma del casco, las máquinas de a bordo, el flujo de la estela y los aspectos operacionales y de mantenimiento se consideran las fuentes principales del ruido submarino radiado generado por los buques. A velocidades de funcionamiento típicas, o cercanas a la velocidad de proyecto del buque, la mayor parte de ruido submarino radiado se debe a la cavitación de la hélice, pero las máquinas de a bordo y los aspectos operacionales también son pertinentes, especialmente por debajo de la velocidad de inicio de la cavitación. El propio ruido de la hélice puede ser un factor preponderante del ruido submarino radiado general. En la estrategia óptima de mitigación del ruido submarino radiado para cualquier

buque deberían tenerse en cuenta al menos todas las fuentes de ruido y estrategias de mitigación pertinentes, incluidas las que no se contemplan en las presentes directrices, que pueden ser más apropiadas para aplicaciones específicas.

Enfoques técnicos y de proyecto para la reducción del ruido

6.2 Las mayores oportunidades para reducir el ruido submarino radiado se presentarán durante las etapas iniciales de proyecto y construcción del buque. Para los buques existentes, probablemente no resultará práctico igualar el nivel de ruido submarino radiado que puede alcanzarse con los proyectos nuevos, con la excepción de la posible modificación de las hélices en algunos casos. Por consiguiente, las consideraciones relativas al proyecto que figuran a continuación están destinadas primordialmente a los buques nuevos. Sin embargo, se puede prestar atención a la modificación de los buques existentes, si esto resulta razonable y práctico. En el cuadro 1 se resumen los enfoques de proyecto y de reducción técnica del ruido aplicables a los buques nuevos y/o existentes.

Proyecto y modificación del casco

6.3 El flujo alrededor del casco puede tener un efecto en el ruido submarino radiado, dado que la forma del casco influye en el flujo entrante de agua en la hélice. Se sabe que los campos de estela irregulares o no homogéneos aumentan la cavitación de la hélice. Por tanto, la forma del casco del buque con sus apéndices debería proyectarse de manera que el campo de estela sea lo más homogéneo posible para reducir la cavitación. Además, no debería despreciarse la excitación de la estructura del buque inducida por la hélice.

6.4 Para reducir el ruido submarino radiado del casco debería tenerse en cuenta el ruido estructural. Algunas medidas de mitigación podrían ser la optimización del escantillonado, la aplicación de un revestimiento de desacoplamiento y la amortiguación estructural.

Proyecto y modificación de la hélice

6.5 Las hélices deberían proyectarse y seleccionarse para reducir al mínimo la cavitación al tiempo que se consideran y optimizan los efectos sobre la eficiencia energética. La cavitación puede ser la fuente predominante de ruido submarino radiado y puede incrementarlo considerablemente. A velocidades de funcionamiento típicas, la cavitación puede reducirse en condiciones de funcionamiento normales mediante un buen proyecto, como la optimización de la carga de la hélice, el mantenimiento de un flujo de agua uniforme hacia las hélices (en lo que influye el proyecto del casco), y la selección meticulosa de las características de la hélice tales como el diámetro, el número de palas, la superficie de las palas, el paso, la inclinación, la caída y las secciones. El análisis y el estudio de la interacción entre el casco y la hélice pueden optimizar simultáneamente el proyecto de la hélice, el casco, el timón y el funcionamiento del buque.

6.6 Para muchas aplicaciones se dispone de opciones de proyecto de la hélice para la reducción del ruido, que deberían tenerse en cuenta. No obstante, se entiende que no siempre se puede utilizar la hélice óptima en cuanto a la reducción del ruido submarino radiado a causa de limitaciones técnicas o geométricas (por ejemplo, el reforzamiento para el hielo de la hélice, la masa). Asimismo, se reconoce que algunos principios de proyecto para la reducción de la cavitación pueden causar una disminución de la eficiencia. Se han elaborado algunos proyectos y conceptos de hélices nuevos y modernos, como las hélices de gran inclinación, de inclinación hacia delante y contrarrotatorias.

6.7 Se dispone de algunas tecnologías emergentes para reducir la potencia de propulsión necesaria, como la propulsión asistida por el viento o la lubricación del casco

mediante inyección de aire. Pueden tenerse en cuenta esas tecnologías para reducir posiblemente la carga de la hélice y el ruido de cavitación. Debería prestarse atención a que la reducción de la carga de propulsión no tenga efectos adversos en el ruido submarino radiado, por ejemplo, generando cavitación en el lado de aspiración con el mismo nivel de carga de potencia. La inyección de burbujas de aire en la popa y la hélice también se utiliza para reducir el ruido submarino radiado.

Mejora del flujo de la estela

6.8 La mejora del rendimiento hidrodinámico mediante la optimización del proyecto de la forma del casco y de los apéndices del casco y la hélice (por ejemplo, mediante la adopción de un dispositivo de mejora de la propulsión/dispositivo de ahorro de energía o un proyecto asimétrico de la popa) puede aumentar el rendimiento y el flujo de entrada a la hélice y reducir el ruido submarino radiado.

6.9 Para mejorar el flujo de entrada de la hélice de un buque pueden utilizarse muchos dispositivos, pero estos pueden provocar cavitación, por lo que deberían proyectarse cuidadosamente, tanto para buques nuevos como para aquellos existentes. El rendimiento en cuanto a cavitación de tales dispositivos podría evaluarse, y el modelo y la hélice podrían someterse a prueba en una instalación de pruebas de cavitación de la siguiente manera:

.1 Instalación de dispositivos de acondicionamiento de la estela y optimización del proyecto del timón.

.2 Estator preturbulencia: algunos estatores antes de la hélice que pueden disminuir el ruido de la frecuencia de paso de la pala y aumentar la eficacia de la hélice.

.3 Álabes precubiertos: álabes y algunos estatores antes de la hélice que pueden mejorar el rendimiento de cavitación de esta y aumentar su eficacia.

.4 Un tapacubos con aletas puede ser útil para mejorar la estela de la hélice de un buque. Puede recuperar energía de la estela de la hélice y aumentar su eficacia. Un tapacubos con aletas también puede contribuir a que se evite la cavitación del vórtice del núcleo.

Proyecto y modificación de las máquinas

6.10 Debería examinarse la selección del sistema de propulsión y las máquinas de a bordo junto con las medidas adecuadas de control del ruido estructural, la ubicación adecuada del equipo en el casco y la optimización de las estructuras de sustentación que pueden contribuir a reducir el ruido submarino radiado y el ruido a bordo que afecta a los pasajeros y la tripulación. La alineación de las máquinas/equipos del buque debería optimizarse cuando sea necesario tener un perfil de ruido reducido. La reducción del ruido submarino radiado puede lograrse asegurando el equipo que posiblemente no sea necesario en todo momento o incluso durante determinadas partes de un tránsito. Además, en función de la configuración de la instalación de propulsión del buque, se puede conseguir una mayor reducción del ruido submarino radiado mediante el funcionamiento selectivo de motores y grupos electrógenos. Por ejemplo, los motores montados a bordo pueden producir un ruido submarino radiado menor que los motores montados fuera borda. Se puede elaborar un "perfil de buque silencioso" midiendo el ruido submarino radiado de varios equipos para comprender la contribución de cada unidad al ruido general del buque.

6.11 El ruido aéreo puede excitar el ruido estructural que se transmite al agua. Los proyectistas y los propietarios y constructores de buques deberían solicitar a los fabricantes de los motores/máquinas información sobre la vibración y los niveles de ruido en el aire que generan sus máquinas para permitir el análisis mediante los métodos descritos en el apéndice 2 y recomendar métodos de instalación que puedan contribuir a que se reduzca el ruido submarino radiado.

6.12 Debería considerarse la posibilidad de utilizar soportes antivibratorios y de mejorar el equilibrio dinámico para máquinas alternativas y rotatorias, como instalaciones frigoríficas, compresores de aire y bombas. El aislamiento de las vibraciones de otros elementos del equipo, tales como el sistema hidráulico, las bombas eléctricas, las tuberías, los ventiladores grandes y los conductos del aire acondicionado, puede resultar beneficioso para algunas aplicaciones, en particular como medida de atenuación en casos en que no sean adecuadas unas técnicas más directas para la aplicación específica objeto de examen. También puede considerarse el control activo del ruido para amortiguar las vibraciones estructurales generadas por estas fuentes.

6.13 Los soportes antivibratorios pueden reducir la vibración desde las máquinas a la estructura de sustentación y el ruido estructural. Por la disposición de la propulsión y la transferencia del empuje pueden considerarse soportes elásticos para motores, principalmente para los de cuatro tiempos con transmisión sin deslizamiento, aunque no para los motores de dos tiempos con transmisión directa. Los motores de dos tiempos no pueden utilizar soportes elásticos, ya que el motor transfiere el empuje de la hélice directamente a la estructura del buque por la gran superficie de asiento del motor. El acoplamiento flexible entre el motor y la caja de cambios puede reducir las vibraciones en una transmisión sin deslizamiento y reducir aún más el ruido estructural. El aislamiento de las vibraciones se utiliza más corrientemente para montar los generadores de diésel en sus sujeciones, a fin de reducir el ruido estructural. En algunos casos, debería considerarse la adopción de un sistema diésel-eléctrico, ya que puede facilitar el aislamiento eficaz de la vibración de los generadores diésel, lo cual normalmente no es posible con las configuraciones grandes de transmisión directa.

6.14 Los sistemas alternativos de alimentación y propulsión pueden ayudar a reducir el ruido submarino radiado. La propulsión eléctrica (por ejemplo, diésel-eléctrica, pila de combustible y totalmente eléctrica o mediante batería, propulsiones en cápsulas o propulsores azimutales) se identifica como una opción de configuración prometedora para reducir el ruido submarino. Es probable que el uso de instalaciones y motores eléctricos de alta calidad contribuya a que se reduzca la vibración inducida en el casco por el motor eléctrico.

Enfoques de mantenimiento y operacionales

6.15 Si bien los componentes principales del ruido submarino radiado dependen del proyecto del buque (es decir, la forma del casco, la hélice, la interacción entre el casco y la hélice y la configuración de las máquinas), debería considerarse la posibilidad de introducir modificaciones operacionales y medidas de mantenimiento para reducir el ruido tanto en los buques nuevos como en los existentes. Los enfoques operacionales podrían resultar especialmente importantes para los buques carentes de características de proyecto o de tecnologías necesarias para reducir el ruido, o para todos los buques que operen en zonas protegidas designadas de carácter nacional o internacional en las que sea necesario adoptar medidas adicionales para reducir los efectos adversos del ruido producido por el tráfico marítimo en la fauna marina. En el cuadro 1 se resumen los enfoques operacionales y de mantenimiento aplicables a los buques nuevos y/o existentes.

Enfoques de mantenimiento

6.16 El mantenimiento de la calidad y el acabado de la superficie de las hélices, por ejemplo mediante una pulimentación correcta, eliminan las incrustaciones biológicas marinas y reducen enormemente la rugosidad de la superficie, con lo cual disminuye la cavitación de la hélice.

6.17 La reducción de la rugosidad del casco y el mantenimiento de una superficie lisa del casco bajo el agua, mediante la utilización de revestimientos adecuados, la limpieza y el mantenimiento proactivo del casco en el agua[1] también pueden mejorar la eficiencia energética de un buque al reducir su resistencia y la carga de la hélice. Sin embargo, hay que tener en cuenta que los sistemas antiincrustantes ultrasónicos emiten energía acústica de alta frecuencia en gamas de frecuencia y a amplitudes que pueden ser perjudiciales para las especies acuáticas. El uso de estos sistemas debería evitarse en la medida de lo posible en las zonas protegidas designadas de carácter nacional e internacional.

6.18 Las vibraciones de las máquinas causan ruido estructural. El mantenimiento adecuado de las piezas móviles y las máquinas, así como los soportes antivibratorios, ayudan a mantener las vibraciones y el ruido a un nivel bajo y evitan que aumente el ruido debido al funcionamiento de dichas máquinas.

Enfoques operacionales

6.19 La optimización del asiento y el calado del buque puede reducir la potencia necesaria y, por tanto, el ruido de cavitación de la hélice.

6.20 Los operadores pueden ajustar y optimizar la ruta del buque, la velocidad y el tiempo de navegación para reducir el tiempo que esté fondeado y el ruido submarino radiado en puerto y zonas costeras. La planificación del viaje puede facilitar el uso de rutas alternativas para evitar las zonas protegidas designadas de carácter nacional e internacional y reducir la velocidad en ellas, cuando pueda hacerse sin peligro, durante las épocas críticas del año para disminuir los efectos del ruido submarino radiado en la fauna marina y las comunidades que dependen de ellas. Las oficinas hidrográficas y las administraciones marítimas deberían considerar la posibilidad de marcar y actualizar las zonas protegidas designadas de carácter nacional e internacional en las cartas para permitir a los marinos y a los usuarios de los puertos planificar los viajes de forma que se reduzcan al mínimo los efectos del ruido submarino radiado de sus buques en la fauna marina.

6.21 Las mejores prácticas incluyen el examen de la información sobre las zonas protegidas designadas de carácter nacional e internacional para determinar si los buques transitan por dichas áreas o realizan operaciones en ellas. Dichas zonas pueden ser, entre otras, regiones cubiertas de hielo marino, e incluyen Inuit Nunaat, puertos y vías de navegación muy transitados que se solapan con hábitats importantes o críticos para especies en peligro, amenazadas o protegidas, zonas importantes para los mamíferos marinos, zonas marinas protegidas según el Convenio sobre la Diversidad Biológica y otras zonas nacionales/regionales protegidas.

6.22 En Inuit Nunaat, algunas características de la región y las actividades que se registran en ella podrían agravar los efectos del ruido submarino radiado. Esto incluye la posibilidad de que se rompa hielo, la presencia de especies sensibles al ruido y la posible interferencia con los derechos de caza de los indígenas. Es aconsejable que los buques que operan en estas

[1] Swain, G., Erdogan, C., Foy, L., Gardner, H., Harper, M., Hearin, J., Hunsucker, K.Z., Hunsucker, J.T., Lieberman, K., Nanney, M. and Ralston, E., 2022. *Proactive In-Water Ship Hull Grooming as a Method to Reduce the Environmental Footprint of Ships*. Frontiers in Marine Science, p.2017.

zonas realicen esfuerzos adicionales para reducir los efectos en la fauna marina, prestando especial atención a la reducción del impacto acústico de la rotura del hielo y a la aplicación de enfoques operacionales y de vigilancia.

Velocidad del buque

6.23 En general, para los buques equipados con hélices de paso fijo, reducir la velocidad del buque, las RPM en el eje y/o la potencia del motor pueden ser medidas operacionales muy eficaces para reducir el ruido submarino, principalmente debido a la reducción de la cavitación. Esto es especialmente cierto cuando las velocidades son inferiores a la velocidad de inicio de la cavitación, pero incluso pequeñas reducciones de potencia pueden causar un descenso considerable de la cavitación. Por lo tanto, se prevé que la limitación de la potencia en el eje o la limitación de la potencia del motor anulables (como las que pueden adoptarse para cumplir las prescripciones sobre el EEXI de la OMI) reducirán el ruido submarino radiado cuando estos límites sean inferiores a la potencia de funcionamiento habitual del buque.

6.24 Se recomienda medir y comprender la velocidad de inicio de la cavitación (CIS) del buque y se operará a una velocidad inferior en las zonas protegidas designadas de carácter nacional e internacional cuando sea factible. En el caso de los buques provistos de hélices de paso variable, es posible que la reducción de la velocidad no produzca una reducción del ruido. Por consiguiente, deberían estudiarse las combinaciones óptimas de la velocidad en el eje y el paso de la hélice.

6.25 No obstante, puede que existan otros motivos de mayor importancia para que se mantenga una velocidad determinada, tales como la seguridad, el funcionamiento y la eficiencia energética. En general, debería examinarse toda velocidad crítica de un buque determinado en relación con la cavitación y los aumentos resultantes del ruido submarino radiado.

Cuadro 1: Resumen de los enfoques de proyecto, técnicos, operacionales y de mantenimiento para la reducción del ruido submarino radiado aplicables a los buques nuevos y/o existentes en la medida de lo posible. Esta lista no es exhaustiva y no debería restringir otras opciones de proyecto que el propietario de un buque pueda considerar como solución. Para más información, consúltense el informe técnico y la matriz de ruido submarino radiado del buque

Enfoques para la reducción del ruido submarino radiado	Buque nuevo	Buque existente
Optimizar el proyecto de la forma del casco del buque (y sus apéndices) para obtener un funcionamiento hidrodinámico y un campo de estela homogéneo que reduzca la cavitación	X	X
Optimizar el proyecto de la hélice para reducir la cavitación, optimizar la carga, garantizar un flujo uniforme del agua y la interacción entre el casco y la hélice, y la selección cuidadosa de las características de la hélice, como el diámetro, el número de palas, la superficie de las palas, el paso, la inclinación, la caída, las secciones y el material innovador	X	X
Tecnologías emergentes como las asistidas por el viento para reducir la carga de las hélices y el ruido de cavitación	X	X
Inyección de aire a la hélice	X	X
Mejora del flujo de la estela	X	X
Selección cuidadosa de las máquinas de a bordo e instalación con medidas adecuadas de control de los niveles de ruido estructural, ubicación adecuada del equipo en el casco y optimización de las estructuras de sustentación	X	
Instalación y aislamiento de las máquinas, por ejemplo, soportes elásticos y acoplamiento flexible en motores de cuatro tiempos con un engranaje reductor, soportes antivibratorios y mejora del equilibrio dinámico para maquinaria alternativa	X	X

Optimizar el asiento del buque para reducir la potencia necesaria y, por tanto, el ruido de cavitación de la hélice	**X**	**X**
Mejorar la planificación de los viajes (por ejemplo, ruta óptima, coordinada entre flotas, zonas protegidas designadas de carácter nacional e internacional/región cubierta de hielo marino, incluidos los hábitats conocidos o las rutas migratorias)	**X**	**X**
Disminuir las RPM de la hélice mediante la reducción de las RPM en el eje y/o de la potencia del motor para los buques equipados con hélices de paso fijo[2]	**X**	**X**
Medidas de organización del tráfico marítimo[3] para evitar las zonas protegidas designadas de carácter nacional e internacional, incluidos los hábitats conocidos o las rutas migratorias	**X**	**X**
Mantenimiento (y limpieza/revestimiento) de la hélice	**X**	**X**
Mantenimiento del casco (revestimiento y mantenimiento y limpieza del casco en el agua, excepto sistemas antiincrustantes acústicos cuando sea posible en zonas protegidas designadas de carácter nacional e internacional)	**X**	**X**

7 EFICIENCIA ENERGÉTICA Y REDUCCIÓN DEL RUIDO SUBMARINO RADIADO

7.1 Debería prestarse atención especial a las interrelaciones entre la eficiencia energética, los GEI y la reducción del ruido submarino radiado, al tiempo que se cumplen las obligaciones reglamentarias y se garantiza que el nivel de ruido submarino radiado cumplirá los objetivos establecidos en el plan de gestión de dicho ruido. Muchas de las opciones de mejora de la eficiencia energética para cumplir las reglas sobre eficiencia energética (EEDI, EEXI y CII) pueden dar lugar a una mejora del rendimiento en cuanto al ruido submarino radiado y podrían traducirse en sinergias positivas con las políticas climáticas. Cuando las medidas de reducción del ruido submarino radiado no favorezcan la eficiencia energética, deberán prevalecer las obligaciones reglamentarias relativas a la eficiencia energética y las emisiones. Las medidas relativas al ruido submarino radiado no deberían ir en detrimento de las prescripciones de la OMI sobre reducción de los GEI y eficiencia energética ni de otras prescripciones de la Organización que afecten a la seguridad de los buques, por ejemplo, la maniobrabilidad.

7.2 Los proyectistas, constructores, propietarios y operadores de buques deberían investigar y tener en cuenta el riesgo de que el ruido submarino radiado aumente con arreglo al proyecto del buque cuando se trate de alcanzar unos valores del EEDI, el EEXI y/o el CII más bajos.

7.3 Debería prestarse especial atención al proyecto del casco y la hélice como unidad, de manera que se cree un campo de estela uniforme para reducir la cavitación de la hélice, ya que de este modo también aumentará la eficiencia energética y se reducirán las emisiones.

7.4 Reducir la cavitación de la hélice es una manera eficaz de reducir el ruido submarino radiado. Las medidas destinadas a reducir la potencia de propulsión aplicada o instalada y la carga del empuje de la hélice, con las restricciones de seguridad apropiadas,[4] son opciones para mejorar la eficiencia energética y reducir las emisiones, y, por lo general, se traducen en una reducción del ruido submarino radiado; por ejemplo, la asistencia eólica, el proyecto optimizado del casco y la limpieza y el mantenimiento periódicos del casco para evitar las

[2] Es vital mantener la velocidad y la potencia suficientes para una navegación segura. Véase la circular MEPC.1/Circ.850/Rev.3: "Directrices para determinar la potencia de propulsión mínima que permita mantener la maniobrabilidad del buque en condiciones desfavorables".

[3] Por "medidas de organización del tráfico marítimo" se entiende el proceso de alejar las vías de navegación existentes y reconocidas de las zonas protegidas nacionales o internacionales que puedan incluir rutas migratorias o hábitats importantes para los mamíferos marinos. Se sabe que la organización del tráfico marítimo es una medida eficaz para reducir la exposición al ruido de los buques en el medio marino.

[4] Véase la circular MEPC.1/Circ.850/Rev.3.

incrustaciones y reducir la resistencia del casco son medidas eficaces para reducir las emisiones y el ruido submarino radiado.

7.5 Los métodos de cálculo del ruido submarino radiado deberían integrar métodos de optimización para incluir los parámetros que afectan a la eficiencia energética y a otras emisiones al mismo tiempo que al ruido submarino. Esto permitirá optimizar el ruido submarino radiado, otras emisiones y la eficiencia/rendimiento.

8 EVALUACIÓN Y VIGILANCIA

8.1 La evaluación y la vigilancia continua del ruido submarino radiado es un paso esencial para evaluar la eficacia de los esfuerzos por reducir el ruido en los océanos. Esto puede hacerse mediante la medición real del ruido submarino radiado del buque, o mediante su modelización, a partir de las características del buque y los parámetros de proyecto, así como de las condiciones ambientales.

8.2 La modelización del ruido submarino radiado debe tener en cuenta la pérdida de propagación del sonido, ya que esta se ve influida por varios parámetros ambientales (por ejemplo, el estado del mar, el hielo marino, el perfil de velocidad del sonido, la temperatura del agua del mar, la absorción del sonido, las corrientes, la batimetría o las propiedades del fondo marino). Existe una gran variedad de modelos de propagación del sonido bajo el agua para abordar los objetivos de la aplicación específica.

8.3 Debería hacerse lo posible por comprender mejor la situación y los cambios en cuanto al ruido submarino radiado. La capacidad de vigilancia desarrollada en colaboración con los puertos interesados debería fomentarse a lo largo de las vías de navegación y utilizarse en programas de incentivos para complementar otros programas de vigilancia del ruido submarino radiado, siempre que sea posible.

8.4 Habría que apoyar los esfuerzos comunitarios para comprender el ruido subacuático del transporte marítimo y sus repercusiones en las especies marinas y las comunidades costeras.

8.5 Los Estados Miembros y otras partes interesadas, incluidas las sociedades de clasificación, los proyectistas, los constructores, propietarios y operadores de buques, los proveedores y los fabricantes pueden aportar datos, en la medida de lo posible, para la comprensión general de las emisiones de ruido de los buques, incluso a través de programas establecidos de vigilancia de los niveles de las fuentes de los buques y/o del ruido ambiental.

8.6 Una vez se hayan recopilado los datos sobre el ruido submarino radiado, los resultados de las medidas aplicadas podrán compartirse presentando al Comité de Protección del Medio Marino, dentro del punto "Otros asuntos", información, observaciones, sugerencias y recomendaciones basadas en la experiencia práctica adquirida mediante la aplicación de estas directrices. Los datos podrán facilitarse anónimamente a fin de apoyar la planificación y la elaboración de medidas relacionadas con el ruido submarino radiado por parte de los Estados Miembros y otras partes interesadas.

9 INCENTIVACIÓN

9.1 Se alienta a las autoridades marítimas, las instituciones financieras y de seguros y a otras entidades a que promuevan el establecimiento de sistemas de incentivos para apoyar la implantación de programas de vigilancia del ruido submarino radiado y los esfuerzos de reducción del ruido por parte de proveedores, proyectistas y constructores, propietarios y operadores de buques, cuando se considere oportuno. Los incentivos pueden apoyar también

la recopilación y el intercambio en general de datos sobre el ruido submarino radiado de los buques.

9.2 La incentivación podría basarse, por ejemplo, en anotaciones de clasificación de los buques pertinentes para el ruido submarino radiado, el reconocimiento de un plan de gestión del ruido submarino radiado, los objetivos de reducción del ruido submarino radiado, las tecnologías y el mantenimiento de los buques y motores, los programas de reducción de la velocidad de los buques, el suministro de energía eléctrica desde tierra en puerto u otras certificaciones voluntarias de sostenibilidad que incluyan pruebas de reducción del ruido submarino radiado o beneficios complementarios sobre eficiencia y mantenimiento (por ejemplo, la prevención de las incrustaciones biológicas mediante la limpieza en el agua del casco y la hélice de los buques podría aumentar la eficiencia y reducir al mínimo la transferencia de especies invasivas).

9.3 Entre los ejemplos de incentivos se encuentran los descuentos en las tasas portuarias, las tasas de paso, o los servicios o productos adicionales y la promoción.

9.4 Los proveedores, proyectistas, constructores, propietarios y operadores de buques deberían concienciarse y esforzarse por conseguir incentivos relacionados con la reducción del ruido submarino radiado.

APÉNDICE 1

NORMAS INTERNACIONALES DE MEDICIÓN DEL RUIDO SUBMARINO RADIADO, RECOMENDACIONES Y REGLAS DE LAS SOCIEDADES DE CLASIFICACIÓN

1 Los propietarios, proyectistas y operadores de buques y otras partes interesadas pueden utilizar, entre las que se enumeran a continuación, la norma de medición del ruido más actualizada y adecuada para su contexto.

2 ANSI S12.64 e ISO-17208-1[5] son dos versiones de la misma norma. Incluía tres grados: levantamiento, aspectos técnicos y precisión, siendo la última la metodología más exacta. La norma ISO-17208-1 se tomó de la norma S12.64 y se adoptó para uso internacional, y la diferencia principal fue que se suprimieron los tres grados. Ambas normas se refieren a la medición del nivel de ruido radiado (RNL) de un buque en aguas profundas. La norma ISO-17208-2[6] proporciona una metodología para tomar datos medidos utilizando la norma ISO-17208-1 y convertir el nivel de ruido radiado medido en el nivel de fuente omnidireccional (MSL). Estas dos normas serían las más pertinentes para la medición del ruido de un buque. Ambas normas serían necesarias si se utilizara el criterio del nivel de fuente omnidireccional.

Lista no exhaustiva de normas de medición del ruido submarino radiado

Norma u organización	Fecha de publicación	Ámbito de aplicación	Metodología	Profundidad mínima del agua
ICES-CRR-209[7]	Mayo de 1995	Se aplica únicamente a los buques de investigación pesquera (R/V). Este documento proporciona orientaciones sobre el ruido ambiental, la audición de los peces, el ruido de los buques, la reacción de los peces al ruido de los buques, la instrumentación del ruido submarino radiado, la mitigación del ruido para los buques de investigación pesquera.	La metodología prevista para los resultados del nivel de presión acústica a 1 metro en un espectro de 1 hercio (banda estrecha). No se indica ningún proceso de corrección de la distancia.	No se especifica.

Norma u organización	Fecha de publicación	Ámbito de aplicación	Metodología	Profundidad mínima del agua
ANSI/ASA S12.64[8]	Septiembre de 2009	Se aplica a cualquier buque de cualquier tamaño con una velocidad inferior a 50 nudos. (Se trata de la primera norma para la medición del ruido submarino radiado de los buques comerciales).	Los resultados se expresan en nivel de presión acústica a 1 m, suponiendo que el buque se modele como una fuente puntual mediante dispersión esférica. Existen tres grados de medición: precisión, aspectos técnicos y levantamiento. Utiliza tres hidrófonos situados en la columna de agua con aspecto de haz.	*Prec.*: 300 m o 3x L *Aspectos técnicos*: 150 m o 1,5x L *Levantamiento*: 75 m o 1x L, donde L es la eslora total del buque.
Bureau Veritas, DNV[9]	Noviembre de 2015	Se aplica a los buques comerciales, lo que incluye cualquier buque dedicado al comercio o al transporte de pasajeros por cuenta ajena.	Los resultados se expresan en nivel de presión acústica a 1 m utilizando las pérdidas de propagación calculadas con el buque modelizado como fuente acústica omnidireccional.	No se especifica.
ISO-17208-1[10]	Marzo de 2016	El mismo que para la norma S12.64 *(supra).*	La metodología y los resultados son en su mayor parte los mismos que para la norma S12.64, pero con un único grado entre los grados de precisión y aspectos técnicos de la norma S12.64. Utiliza tres hidrófonos situados en la columna de agua con aspecto de haz.	Superior a 150 m o la que se indica en la nota 1).

			proporciona los límites y la necesidad de llevar a cabo la medición de conformidad con DNVGL-CG-0313 (véase *supra*).	
ABS[18]	Mayo de 2021	Se aplica a cualquier buque de investigación o comercial autopropulsado.	Los resultados se expresan en nivel de presión acústica a 1 m utilizando la dispersión esférica para aguas profundas y la pérdida de propagación calculada (mediante la ecuación facilitada) para aguas poco profundas. Utiliza tres hidrófonos situados en la columna de agua con aspecto de haz.	Superior a 60 m o la que se indica en la nota 4).
RINA[19]	2021	Se aplica a todos los buques que deseen obtener las anotaciones *DOLPHIN QUIET* o *TRANSIT* de RINA.	Los resultados se expresan en nivel de presión acústica a 1 m, suponiendo que el buque se modelice como una fuente puntual mediante dispersión esférica. Utiliza tres hidrófonos situados en la columna de agua con aspecto de haz.	150 m o la que se indica en la nota 5).
Korean Register[20]	Julio de 2021	Se aplica a los buques nuevos y existentes que hayan solicitado la anotación opcional relativa al ruido submarino radiado de un buque.	Los resultados se expresan en nivel de presión acústica a 1 m	60 m como mínimo

NOTAS SOBRE LA PROFUNDIDAD MÍNIMA DEL AGUA:

1. ISO-17208-1: 1,5 x eslora total del buque, que es la distancia longitudinal entre la parte más a proa y la más a popa de un buque.

2. Lloyds Register: 0,3 x v^2, donde v es la velocidad del buque en m/s o 3 x $(B \times Dt)^{1/2}$, donde B es la manga del buque y Dt es su calado, ambos en metros.

18 American Bureau of Shipping (ABS), *Underwater Noise and External Airborne Noise*, mayo de 2021.

19 Registro Italiano Navale (RINA), Dolphin Quiet Ship y Dolphin Transit Ship, 2021.

20 Korean Register: *Guidance for Underwater Radiated Noise* (julio de 2021).

3. Bureau Veritas: 0,3 x v^2, donde v es la velocidad del buque en m/s. Se considerará aguas profundas un valor de 200 m o igual a 2 veces la eslora del buque, a menos que el buque mida más de 200 m, en cuyo caso el valor de referencia será igual a 1,5 veces la eslora del buque.

4. ABS: 0,3 x v^2, donde v es la velocidad del buque en m/s. Se considerará aguas profundas el valor mayor entre 150 m y 1,5 veces la eslora del buque.

5. RINA: Las mediciones pueden realizarse en aguas poco profundas siempre que se haya acordado con RINA un procedimiento adecuado para la pérdida de propagación real.

APÉNDICE 2

TIPOS DE MODELOS INFORMÁTICOS PARA OPTIMIZAR EL PROYECTO DE LOS BUQUES Y LOS ENFOQUES TÉCNICOS DE REDUCCIÓN DEL RUIDO SUBMARINO RADIADO

Los tipos de modelos informáticos para optimizar el proyecto de los buques y los enfoques técnicos de reducción del ruido submarino radiado son:

.1 **Características del flujo:** puede utilizarse la dinámica de fluidos computacional (CFD) para predecir y visualizar las características del flujo, la cavitación y las fuentes hidroacústicas alrededor del casco y los apéndices, así como el campo de la estela en el que opera la hélice. Para predecir y probar el efecto de la cavitación en el funcionamiento de la hélice pueden utilizarse también métodos de análisis de hélices, como los métodos de superficie sustentadora o la CFD.

.2 **Radiación del ruido:** pueden utilizarse el análisis por el método de los elementos finitos, el método de elementos de contorno y el análisis estadístico de la energía para calcular el ruido radiado debido al campo del flujo, la cavitación y las excitaciones de las máquinas. Se pueden tener en cuenta la batimetría, el fondo marino, la superficie del mar y las estructuras elásticas de los buques. Otros métodos para predecir la radiación son los métodos híbridos, los métodos basados en las ondas y el método del flujo de energía. La mayoría de los métodos pueden utilizarse tanto para estructuras como para fluidos.

.3 **Propagación del ruido:** el trayecto del ruido desde la fuente hasta el receptor depende del entorno y de algunas características del sonido. Para modelizar la propagación del sonido a larga distancia pueden utilizarse métodos como la teoría de los rayos, los modos normales, la integración del número de ondas o las ecuaciones parabólicas.

Los ensayos con modelos normalizados del ruido submarino radiado de la hélice en combinación con las pruebas de cavitación ofrecen la posibilidad de que los fabricantes, los proveedores y los propietarios y constructores de buques acuerden si se cumplen las especificaciones contractuales relativas a la contribución de la hélice al ruido submarino radiado antes de que se construya el buque.

.1 Las pruebas de cavitación a escala de modelo[21] pueden ofrecer en la actualidad la predicción y el ensayo más precisos de los niveles de fuente del ruido submarino radiado de las hélices cavitantes, lo cual indica una concordancia entre buena y aceptable con los ensayos en el mar respecto de los niveles de fuente del ruido submarino radiado. Sin embargo, los efectos de escala y el efecto de los ruidos de fondo y reverberación de las instalaciones deberían examinarse cuidadosamente, y se esperan nuevas mejoras en estos temas a partir de los estudios en curso. Además, como estas pruebas con modelos se centran únicamente en el ruido de la cavitación, se puede evaluar bien el efecto de una medida de atenuación del ruido de la cavitación. El efecto de esta medida de mitigación en el ruido total

[21] ITTC – *Recommended Procedures and Guidelines, Model-Scale Propeller Cavitation Noise Measurements*, 7.5–02–03–03.9

del buque requiere conocer las demás fuentes de ruido, como el ruido de las máquinas y el ruido estructural.

.2 Podrían realizarse pruebas con modelos del buque, su hélice y los apéndices especiales (como el soporte del eje, el estabilizador de aletas, etc.) en una instalación de pruebas de cavitación, por ejemplo un túnel de cavitación, para medir los aspectos del proyecto con respecto a los impulsos de presión inducidos por la cavitación, la velocidad de inicio de la cavitación y el ruido radiado.

Las predicciones y pruebas con modelos sobre el ruido submarino radiado deberían evaluarse, cuando sea posible, con pruebas de validación del modelo a escala o a tamaño real, preferiblemente en entornos controlados.

APÉNDICE 3

MODELOS DE PLANTILLAS PARA LA PLANIFICACIÓN DE LA GESTIÓN DEL RUIDO SUBMARINO RADIADO

Para ayudar a los propietarios de buques en la elaboración de un plan de gestión del ruido submarino radiado que pueda adaptarse a sus necesidades, se facilitan dos plantillas como muestra de lo que dicho plan puede contener. Las plantillas se proporcionan únicamente a título orientativo y pueden modificarse para abordar contextos específicos de propietarios de buques concretos.

Modelo de plantilla nº 1: Plan de aspiraciones con pasos iniciales:

Plan de gestión del ruido submarino radiado

1 *Objetivo*

Esta sección debería incluir una visión general del objetivo de alto nivel relativo a la reducción del ruido submarino radiado de los buques. Por ejemplo, podría formularse así: "En los próximos cinco años, nos proponemos alcanzar los siguientes objetivos [....] y determinar oportunidades nuevas para reducir el ruido de nuestros buques".

2 *Enfoque*

En esta sección deberían describirse los diversos esfuerzos que se realizarán para alcanzar el objetivo general. Entre ellos pueden encontrarse las inversiones en investigación, los esfuerzos para medir la firma acústica de los buques o la determinación/implantación de soluciones operacionales o técnicas pertinentes para un buque.

3 *Métodos de vigilancia/evaluación*

Esta sección debería incluir un breve resumen de cómo el propietario/operador del buque prevé vigilar y evaluar el progreso de su plan a lo largo del tiempo.

Modelo de plantilla nº 2: Plan detallado que siga más explícitamente el ciclo planificar-implantar-vigilar-evaluar

Plan de gestión del ruido submarino radiado

1 Visión general

Esta sección debería incluir una visión general del objetivo de alto nivel relativo a la reducción del ruido submarino radiado de los buques y el objetivo del plan. Por ejemplo, podría formularse así: "En los próximos cinco años, nos proponemos alcanzar los siguientes objetivos [....], implantar las medidas siguientes [...] y determinar oportunidades nuevas para reducir el ruido de nuestros buques".

2 Ruido submarino radiado de referencia

Esta sección debería ofrecer una visión general de cómo podría determinarse un ruido submarino radiado de referencia.

En la medida de lo posible, debería intentarse determinar una referencia para el buque. La condición de ruido submarino radiado de referencia del buque puede predecirse (métodos informáticos/empíricos/pruebas con modelos) o, preferiblemente, medirse. La determinación de la referencia para la condición del buque relativa al ruido submarino radiado prevista y/o medida debería llevarse a cabo en las condiciones normales de funcionamiento del buque, incluidos una velocidad operacional y un calado típicos, con el uso de equipos/máquinas de funcionamiento estándar.

El ruido submarino radiado debería medirse con arreglo a una norma objetiva. En el apéndice 1 se resume la disponibilidad de normas de medición reconocidas que se han utilizado en la investigación y para apoyar los programas en los puertos. En el apéndice 2 figuran ejemplos de modelos informáticos para optimizar el proyecto de los buques y los enfoques técnicos de reducción del ruido.

3 Objetivos relativos al ruido submarino radiado

Esta sección debería describir los objetivos generales de reducción del ruido de la fuente que el plan pretende alcanzar. La información que figura a continuación ofrece algunas posibles orientaciones sobre cómo podrían establecerse dichos objetivos.

La investigación ha documentado una variabilidad significativa entre regiones en las condiciones de propagación del sonido submarino, las contribuciones a los niveles de ruido submarino radiado y la sensibilidad auditiva y las respuestas fisiológicas o de comportamiento adversas al ruido de los buques entre las especies marinas. Por tanto, es probable que los límites de ruido basados en la biología reflejen esta variabilidad, y que cualquier límite universal sirva como resumen de los intereses de reducción de los efectos en diversos entornos. No obstante, pueden establecerse objetivos individuales relativos al ruido de acuerdo con la clasificación del buque, el arqueo u otra característica, a partir de las mediciones de referencia, reales o previstas. Estos objetivos de reducción del ruido submarino radiado pueden reforzarse gradualmente a lo largo de un periodo determinado, que deberá establecer el propietario del buque.

Los objetivos relativos al ruido submarino radiado para un buque determinado deberían tener en cuenta su finalidad y tipo, la predicción sobre el ruido submarino radiado y la medición de referencia, así como consideraciones operacionales. Los objetivos de reducción del ruido submarino radiado pueden establecerse también mediante la adopción de uno de los conjuntos de reglas relacionadas con el ruido submarino radiado de las sociedades de clasificación. Como alternativa, los propietarios de buques pueden establecer objetivos de reducción del ruido submarino radiado, entre otras cosas, reduciendo los niveles de ruido en un porcentaje determinado.

4 Enfoques de reducción del ruido submarino radiado y medidas conexas

Esta sección brinda la oportunidad de articular claramente los enfoques que deben adoptarse para reducir el ruido submarino. Esto podría incluir una combinación de enfoques técnicos y operacionales, que podrían adaptarse con el tiempo. También puede incluir la determinación de iniciativas de investigación u otros proyectos de colaboración para avanzar en el conocimiento y la concienciación sobre los esfuerzos de reducción del ruido submarino radiado. Véase la sección 6 de las directrices para orientarse sobre los tipos de enfoques que podrían utilizarse.

5 Vigilancia y evaluación

Esta sección debería indicar cómo podrían vigilarse y evaluarse los esfuerzos de reducción del ruido de los buques.

Como parte de la planificación de la gestión del ruido submarino radiado, los propietarios y operadores de buques deberían elaborar un enfoque de vigilancia para evaluar periódicamente la eficacia de los esfuerzos de reducción del ruido de los buques en comparación con las mediciones de referencia y los objetivos del ruido submarino radiado y para orientar y mejorar las actividades dirigidas a la reducción del ruido (sección 8). Dicha evaluación puede incluir formas de medición del ruido submarino radiado, simulaciones, modelización u otros métodos científicos de recopilación y evaluación de datos.

Debería considerarse la posibilidad de medir el ruido submarino radiado del buque procedente de las fuentes de ruido identificadas en la gama prevista de condiciones típicas de funcionamiento para determinar si se cumplen los objetivos relativos al ruido submarino radiado del buque. De este modo, los operadores de buques podrían optimizar su funcionamiento y ajustar adecuadamente los niveles del ruido submarino radiado a lo largo de una ruta (por ejemplo, optimizando el asiento del buque, reduciendo así la potencia necesaria, o reduciendo la velocidad, cuando sea seguro hacerlo, lo que posiblemente haga disminuir el ruido de cavitación de la hélice). La verificación del mantenimiento de niveles de ruido previamente aceptables también puede demostrarse mediante registros de mantenimiento adecuado del casco, las máquinas y la hélice.

Entre las actividades de medición, el ruido submarino radiado puede vigilarse *in situ*. La elaboración de herramientas dinámicas de optimización del viaje en tiempo real que proporcionen información analítica personalizada para aumentar la eficacia, ahorrar en combustible y costes y reducir las emisiones resulta prometedora para una gestión adaptativa. La reducción del ruido debería añadirse como opción de optimización.

1. Introducción

El sector marítimo-portuario se enfrenta a desafíos que van desde la adaptación a los efectos derivados de la pandemia, navegar por una crisis económica mundial y tensiones geopolíticas, así como el impulso a la digitalización, entre otros; sin embargo, el problema apremiante es la necesidad de eliminar sus impactos ambientales, especialmente en la contaminación atmosférica.

El transporte marítimo es la forma predominante de la movilidad internacional de mercancías, que representa más del 80 % del volumen del comercio mundial; en México, es el segundo modo de transporte para el comercio exterior: 38% de las importaciones y 20% de las exportaciones se realizan por este medio, a través de los 103 puertos y 15 terminales habilitadas que integran el Sistema Portuario Nacional (SPN), que, en 2023, movilizaron más de 294 millones de toneladas.

Por su parte, a nivel mundial, las emisiones de gases de efecto invernadero (GEI) generadas por el transporte marítimo representan 3%[1] del total de las emisiones totales. Esto ha motivado a una mayor presión internacional para reducir y, en última instancia, eliminar sus impactos ambientales; especialmente en el cambio climático y la contaminación del aire. No hay duda de que el mundo enfrenta las consecuencias del cambio climático y el sector portuario no está exento de sus efectos con impactos directos en la cadena global de suministros y pérdidas económicas.

De acuerdo con el estudio del Banco Mundial[2] y el Panel Intergubernamental de Cambio Climático, el mundo corre el riesgo de que, para finales de siglo, la temperatura mundial aumente 4^0 C, si no se muestran cambios en las políticas internacionales. Por nuestra parte, México, al firmar el Acuerdo de París, se comprometió a reducir sus emisiones de GEI expresados en la Contribución Nacional Determinada (NDC) 2022, con una meta de 35% para 2030, con respecto a su línea base.

Es el momento de reorientar esfuerzos y voluntades para dar soluciones decisivas a la gran problemática que se presenta; no sólo en nuestro país, sino a nivel mundial. Tenemos que vincular y coordinar los esfuerzos en el sector portuario para darle cohesión a los objetivos, metas y compromisos firmados por nuestro país, con apego a las normatividades establecidas.

Para lograrlo, la Secretaría de Marina (SEMAR), a través de la Coordinación General de Puertos y Marina Mercante (CGPMM), ha estructurado la ***Estrategia de Descarbonización de Puertos*** (EDP) que está alineada con el Acuerdo de Paris, los Objetivos de Desarrollo Sostenible de la Agenda 2030, la Estrategia de Instrumentación para una Economía Oceánica Sostenible y, la Estrategia Revisada de la Organización Marítima Internacional (OMI) relacionadas con la descarbonización del transporte marítimo. Esta estrategia es impulsada en la Comisión Intersecretarial de Mares y Costas (CIMARES) en la que participan nueve Secretarías de Estado, encabezadas por la SEMAR: Gobernación, Medio Ambiente y Recursos Naturales, Relaciones Exteriores, Economía, Bienestar, Agricultura y Desarrollo Urbano, Turismo y, Energía,

En la EDP se delimitan acciones tendientes a que los puertos, a través de las Administraciones del Sistema Portuario Nacional (ASIPONAS) y las Administraciones Portuarias Integrales (APIS), mantengan actualizado **un inventario de emisiones** y, en paralelo, se promuevan la digitalización, la optimización de procesos, la eficiencia energética y el fortalecimiento de la relación puerto-ciudad, mediante acciones como proyectos de infraestructura sustentables, reforestación, limpieza de playas y campañas de concientización, entre otras.

[1] Cuarto Estudio de la OMI sobre los GEI (2020)
[2] Turn down the heat, The World Bank, 2013

Por lo anterior, para trazar una ruta de descarbonización en los puertos mexicanos, además de un ejercicio de reflexión colectiva, es preciso definir objetivos y metas que involucren a todos los agentes de la cadena logística y orientar los esfuerzos hacia la reducción de emisiones, la eliminación y el almacenamiento de dióxido de carbono a través de procesos que no están relacionados directamente con el consumo energético, pero que se relacionan con problemas ambientales en las ciudades portuarias.

2. Factor detonante de la Estrategia

2.1 El cambio climático

El cambio climático afecta directamente a las redes globales de transporte y la infraestructura portuaria. Entre los ejemplos de eventos climáticos están: elevación del nivel del mar, marejadas ciclónicas, intrusión de agua salada, vientos y lluvias intensas, tormentas eléctricas, desbordamiento de ríos, temperaturas extremas, sedimentación, sequía, reducción del flujo de agua de los ríos y la erosión costera (BID, 2021). Estos eventos pueden dañar, deteriorar o destruir infraestructura esencial para el funcionamiento de los puertos, pero también, ocasionar accidentes o la interrupción temporal y/o permanente de actividades y operaciones logísticas (CEPAL, 2023).

Por otra parte, los riesgos conllevan efectos económicos como: aumento de costos, mantenimiento adicional y gastos no previstos que implicarán pérdida de competitividad y afectaciones en la cadena de suministro.

Cuadro 1. Elementos y potenciales áreas de impacto del cambio climático en puertos

Elementos	Potenciales áreas de impacto
Infraestructura del puerto	• Rompeolas • Muelles • Patios • Bodegas • Equipos • Edificios • Infraestructura eléctrica • Infraestructura de drenaje
Acceso al puerto	• Caminos/pavimento • Vía férrea • Vías navegables internas • Navegabilidad reducida • Requerimientos de dragado • Restricciones del tamaño de las embarcaciones
Operaciones del Puerto	• Condiciones de navegación • Atraque y amarre • Actividades de carga y descarga • Transporte en tierra más allá del puerto • Almacenamiento de bienes • Costos energéticos • Condiciones de trabajo
Ambiente físico	• Línea costera • Área de estuarios/costa • Área de ríos/riberas
Factores socioeconómicos	• Población (p.ej. desplazamiento) • Actividad económica marítima • Actividad económica terrestre • Patrones de demanda/comercio/mercado • Desempeño social • Pesca e infraestructura relacionada
Medio ambiente	• Hábitats • Hábitats protegidos • Especies (ej., peces, aves) • Especies protegidas
Otros	• Costo o disponibilidad de seguros • Confiabilidad en el puerto • Reputación del puerto • Riesgo de incendio

Fuente: BID (2021)

En nuestro país, la búsqueda de soluciones al cambio climático recae, en primera instancia, en el Gobierno Federal, para lo cual, cuenta con dependencias, institutos y organizaciones dedicadas a la atención de los problemas. En particular, en materia portuaria, la Secretaría de Marina quien, a través de la CGPMM, le corresponde proponer, estudiar, analizar y emitir los mecanismos necesarios y suficientes que resuelvan de manera eficiente y eficaz los problemas de contaminación ambiental con la participación directa de las ASIPONAS y APIS para el cumplimiento de los compromisos portuarios, tanto en el ámbito internacional como nacional.

Por tal motivo, se desarrollan acciones orientadas hacia: la planificación y gestión del atraque de buques, manejo de grúas, agrupación de materiales, gestión de patios, almacenaje, reposicionamiento de materiales, desagregación y distribución de la carga, entre otros, con los que busca involucran a los actores portuarios para estrechar lazos de cooperación y activar la estrategia a seguir. En tal sentido, la EDP será el eje transversal que determine la puesta en marcha de proyectos y acciones de mitigación y adaptación para la reducción de emisiones.

3. Fuentes Normativas

3.1 Ámbito internacional

Conferencia de las Naciones Unidas: Acuerdo de París

Tanto el Acuerdo de París, y sus objetivos adoptados en la Conferencia de las Naciones Unidas sobre el Cambio Climático (COP 21); como el Pacto de Glasgow por el Clima en la COP 26 y el Plan de implantación de Sharm el-Sheikh en la COP 27 son el esfuerzo internacional para hacer frente a las emisiones de GEI. En el Acuerdo se definió como objetivo: "*mantener el aumento de la temperatura media mundial muy por debajo de 2° C, con respecto a los niveles preindustriales y proseguir los esfuerzos para limitar ese aumento de temperatura a 1.5° C con respecto a esos niveles"*. En estos esfuerzos se reconoce que, de lograrlo, se reducirían significativamente los riesgos y repercusiones asociados al cambio climático.

Organización de las Naciones Unidas (ONU): Objetivos del Desarrollo Sostenible (ODS)

Los 17 ODS de la Agenda 2030, aprobados en 2015 y adoptados por más de 150 países -México, incluido- abarcan temas como: justicia, instituciones sólidas, pobreza, derechos sociales básicos, crecimiento económico, innovación, inclusión social, desigualdad y sostenibilidad ambiental. Los ODS son el eje principal para el desarrollo de la planeación nacional a largo plazo.

La estrategia de Descarbonización de Puertos está alineada con:

- Objetivo 9: Industria, innovación e infraestructuras;
- Objetivo 13: Adoptar medidas urgentes para combatir el cambio climático y sus efectos y;
- Objetivo 14: Conservar y utilizar en forma sostenible los océanos, los mares y los recursos marinos para el desarrollo sostenible.

3.2 Nivel Sectorial Internacional

Organización Marítima Internacional (OMI)

Actualmente, la cadena de logística se encuentra bajo presión para reducir su huella de carbono. Por ello, en 2018, la OMI aprobó la Estrategia inicial sobre la reducción de las emisiones de GEI procedentes de los buques (resolución MEPC.304(72)) reafirmando su compromiso con la reducción de las emisiones de GEI del transporte marítimo internacional y con el objetivo de eliminarlas por completo y lo antes posible. Esta acción considera, por primera vez, una reducción

de las emisiones de GEI totales del transporte marítimo y envió una señal al sector marítimo sobre la necesidad de estimular inversiones para desarrollar combustibles con emisiones de carbono bajas o nulas y tecnologías innovadoras con una buena eficiencia energética.

Previamente, en 2016, en el seno del MEPC (Comité de protección del medio marino de la OMI) se aprobó el primer documento: "Hoja de ruta para elaborar una estrategia detallada de la OMI sobre la reducción de las emisiones de GEI procedentes de los buques", en la que se señaló que, para 2023, debía adoptarse una Estrategia revisada.

La Estrategia (2023) de la OMI sobre los GEI representa la labor de la OMI, como órgano internacional competente, para hacer frente a las emisiones de GEI del transporte marítimo. En ésta, se establecen niveles de ambición y puntos indicativos para la reducción de las emisiones de GEI de los buques (resolución 7 de julio de 2023 MEPC80):

Cuadro 2: Niveles de ambición establecidos en la Estrategia 2023 de la OMI

Nivel	Precisión
1. La intensidad de carbono de los buques disminuirá mediante la mejora de la eficiencia energética de los buques nuevos.	Examinar con el propósito de reforzar las prescripciones de proyecto de eficiencia energética para los buques;
2. La intensidad de carbono del transporte marítimo internacional disminuirá.	Reducir las emisiones de CO2 por trabajo de transporte, como promedio para todo el transporte marítimo internacional, en al menos un 40 % para 2030, comparado con los niveles de 2008
3. La adopción de fuentes de energía, combustibles y/o tecnologías de emisiones nulas o casi nulas de GEI aumentará.	La adopción de fuentes de energía, combustibles y/o tecnologías de emisiones nulas o casi nulas de GEI **representará, como mínimo, el 5 %, con el objetivo de llegar al 10 %, de la energía utilizada** por el transporte marítimo internacional para 2030
4. Las emisiones de GEI procedentes del transporte marítimo internacional llegarán a ser netas nulas	Alcanzar el punto máximo de emisiones de GEI procedentes del transporte marítimo internacional lo antes posible y **llegar a unas emisiones netas nulas de GEI en 2050,** a más tardar, o alrededor de ese año, es decir, cerca de 2050, teniendo en cuenta las diferentes circunstancias nacionales, al tiempo que prosiguen los esfuerzos para su eliminación progresiva

Fuente: Estrategia de 2023 de la OMI sobre la reducción de las Emisiones de GEI procedentes de los buques MEPC 80

Cuadro 3: Puntos de comprobación indicativos para alcanzar unas emisiones netas nulas de GEI procedentes del transporte marítimo internacional definidos en la Estrategia 2023 de la OMI:

1. Reducir el total de las emisiones anuales de GEI procedentes del transporte marítimo internacional en, al menos, 20 % esforzándose por alcanzar el 25% para 2030, en comparación con 2008.
2. Reducir el total de las emisiones anuales de GEI procedentes del transporte marítimo internacional en, al menos, 70 % esforzándose por alcanzar el 75% para 2040, en comparación con 2008.

Fuente: Estrategia de 2023 de la OMI sobre la reducción de las Emisiones de GEI procedentes de los buques MEPC 80

3.3 Ámbito nacional

Ley General de Cambio Climático

Por nuestra parte, el Gobierno de México publicó la Ley General de Cambio Climático en la que se establecen las obligaciones del Estado Mexicano para regular e incentivar las acciones enfocadas a combatir los efectos de cambio climático. De esta manera, se refiere que:

- Artículo 6°: Las atribuciones que la presente ley otorga a la federación serán ejercidas por el Poder Ejecutivo federal a través de las dependencias y entidades que integran la

administración pública federal centralizada y paraestatal, de conformidad con las facultades que les confiere esta ley, la Ley Orgánica de la Administración Pública Federal, la Ley Federal de las Entidades Paraestatales y demás disposiciones jurídicas aplicables.

- Artículo 7o. Son atribuciones de la federación las siguientes:
  - VI. Establecer, regular e instrumentar las acciones para la mitigación y adaptación al cambio climático, de conformidad con esta Ley, los tratados internacionales aprobados y demás disposiciones jurídicas aplicables...
  - VII. Incorporar en los instrumentos de política ambiental criterios de mitigación y adaptación al cambio climático;
  - XIV. Formular y adoptar metodologías y criterios, expedir las disposiciones jurídicas que se requieran para la elaboración, actualización y publicación del inventario y en su caso los inventarios estatales;
  - XVIII. Establecer las bases e instrumentos para promover y apoyar el fortalecimiento de la competitividad de los sectores productivos transitando hacia una economía sustentable de bajas emisiones de carbono, mejorando su eficiencia energética, participando en el comercio de emisiones y en mecanismos de financiamiento nacionales o internacionales;
  - XIX. Determinar los indicadores de efectividad e impacto que faciliten la evaluación de los resultados de la aplicación del presente ordenamiento e integrar los resultados al Sistema de Información sobre el Cambio Climático;
  - XXIII. Desarrollar estrategias, programas y proyectos integrales de mitigación y adaptación al cambio climático en materia de hidrocarburos y energía eléctrica, para lograr el uso eficiente y sustentable de los recursos energéticos fósiles y renovables del país, de conformidad con la Ley para el Aprovechamiento Sustentable de la Energía y la Ley para el Aprovechamiento de Energías Renovables y el Financiamiento de la Transición Energética, en lo que resulte aplicable.

Plan Nacional de Desarrollo (PND)

La Constitución Política de los Estados Unidos Mexicanos (CPEUM) reconoce el derecho de todas las personas a un medio ambiente sano para su desarrollo y bienestar (art. 4°), así como a la construcción territorial (art.42° al 48°). En concordancia, el Plan Nacional de Desarrollo (PND) 2019-2024 establece que la preservación del medio ambiente debe permear todas las políticas públicas y las acciones del gobierno.

Derivado del PND. el Objetivo General 3 “Desarrollo Económico” se enfatiza que es necesario “Desarrollar de manera transparente, una red de comunicaciones y transportes accesible, segura, eficiente, sostenible, incluyente y moderna, con visión de desarrollo regional y de redes logísticas que conecte a todas las personas, facilite el traslado de bienes y servicios, y que contribuya a salvaguardar la seguridad nacional” (Objetivo 3.6).

Secretaría de Medio Ambiente y Recursos Naturales (SEMARNAT)

La SEMARNAT informó, mediante comunicado oficial del 15 de noviembre de 2022, el compromiso adquirido por el Gobierno de México en la 27 Conferencia de las Partes (COP27) de la Convención Marco de Naciones Unidas sobre el Cambio Climático para reducir 35% de sus Gases de Efecto Invernadero (GEI) para el 2030.

3.4 Nivel Sectorial Nacional

Ley de Puertos (LP)

La Ley de Puertos en su Artículo 26, fracción VI, establece: "*El título de concesión, según sea el caso, deberá contener, entre otros los programas de construcción, expansión y modernización de la infraestructura portuaria, los cuales se apegarán a las disposiciones aplicables en materia de protección ecológica*".

Reglamento de la Ley de Puertos (RLP)

Derivado de la Ley de Puertos, en su Reglamento se menciona que:

- Artículos 78, 79 y 80: establecen con precisión los requisitos sobre el manejo de desechos y aguas residuales que deberán acreditar los prestadores de servicios.
- Artículo 85 fracciones I y XIV: las Reglas de Operación deberán contener las condiciones en materia de construcción, explotación y operación para asegurar que la ejecución de las obras no afectará la continuidad, la eficiente operación y sustentabilidad ecológica del puerto… y el control ambiental y prevención contra la contaminación…
- Artículo 124: los trabajos que se hagan en los buques deberán cumplir con las normas relativas a la prevención de la contaminación.

Títulos de Concesión

En los Títulos de Concesión de las ASIPONAs, la cláusula (XVIII) establece la obligatoriedad de preservación del ambiente: al realizar cualesquiera actos en ejercicio de esta concesión, la Concesionaria deberá cumplir con las disposiciones legales, reglamentarias y administrativas, así como con los tratados internacionales celebrados y ratificados por México en materia de equilibrio ecológico y protección al ambiente.

Contratos de Cesión Parcial de Derechos y Obligaciones

De igual forma, los Contratos de Cesión Parcial de Derechos y Obligaciones suelen contener una cláusula relativa a necesidad de preservar el medioambiente, como puede ser:

> *"… el Cesionario deberá cumplir con las disposiciones legales, reglamentarias y administrativas vigentes en materia de equilibrio ecológico y protección del medio ambiente, así como con los tratados internacionales celebrados y ratificados por México que sean aplicables al caso…"*

Además, se alude a las certificaciones con las que deberán cumplir:

> *"… las emisiones contaminantes a la atmósfera, sean fuentes artificiales o naturales, fijas o móviles, deben ser reducidas y controladas, para asegurar una calidad del aire satisfactorio para el bienestar de la población y el equilibrio ecológico…".*

Dentro de este marco, México ha adoptado las siguientes acciones:

- En el periodo 2016-2023 la CGPMM ocupó la presidencia del Comité Técnico Consultivo (CTC) en Gestión Portuaria Sostenible y Protección Ambiental de la Comisión Interamericana de Puertos de la Organización de Estados Americanos. (CIP-OEA).
- A través de la Secretaría de Relaciones Exteriores (SRE)En 2020, México se integró al Panel de Alto Nivel para una Economía Oceánica Sostenible, de la ONU, integrado por 14 países. En diciembre de ese mismo año, se iniciaron los Planes Oceánicos Sostenibles para el 100% de sus aguas nacionales, adaptándolo a sus capacidades y al contexto nacional a través de una estrategia de instrumentación en la cual participan además nueve dependencias gubernamentales: SEMAR, SHCP, BIENESTAR, SEMARNAT, SENER, ECONOMÍA, SADER, SEP y SECTUR.
- Posteriormente, en 2021, a través de la Comisión Intersecretarial para el Manejo Sustentable de Mares y Costas (CIMARES), se expide la Estrategia de Instrumentación para una

Economía Oceánica Sostenible (EIEOS) México 2021-2024, publicada el 12 de agosto de 2022 en el Diario Oficial de la Federación (DOF).

- Con base en la EIEOS, una economía sostenible basada en el océano puede desempeñar un papel esencial en esta reducción de emisiones, a la vez que proporciona empleos, apoya la seguridad alimentaria, sostiene la diversidad biológica y mejora la resiliencia. Las acciones climáticas basadas en el océano pueden proporcionar hasta un quinto de las reducciones anuales de emisiones de gases de efecto invernadero necesarias para limitar el calentamiento a 1.5°C para el 2050.

La CGPMM en pleno ejercicio y cumplimiento de las atribuciones y funciones, y, a través del equipo de trabajo responsable de esta temática trabaja en la búsqueda y definición de alternativas y propuestas para el ámbito portuario. Lo anterior, con el propósito de orientar la toma de decisiones de los involucrados para la puesta en práctica de acciones concretas dirigidas a la obtención de resultados favorables y reducir los niveles de contaminación ambiental y mejorar la calidad de ambiental en los puertos. Con lo anterior como preámbulo es que se presenta la Estrategia de Descarbonización de los Puertos cuyo que marca el punto focal de arranque en favor de acciones de mayor envergadura y alcance en el conforman el Sistema Portuario Nacional.

4. Estrategia de Descarbonización de Puertos

La Coordinación General de Puertos y Marina Mercante ha trabajado en la elaboración de la *Estrategia de Descarbonización de Puertos* (EDP) que integra propuestas y lineamientos generales de política ambiental, y promueve el diseño e instrumentación de acuerdos de colaboración interinstitucional con autoridades y concesionarios de infraestructura portuaria. Para cumplir con este propósito, es necesario impulsar la coordinación inter e intrainstitucional.

4.1 Premisas y consideraciones

- Aunado a la preocupación histórica por los contaminantes atmosféricos, en la última década ha aumentado la inquietud por las emisiones de GEI ha aumentado en el sector marítimo portuario, por lo que se realizan esfuerzos por generar estrategias que reduzcan las emisiones (siendo ahora un deber más que una opción).
- Los puertos como centros multimodales de la cadena logística para el movimiento e intercambio de mercancías, así como para el embarque y desembarque de personas, constituyen zonas de actividades impulsadas fundamentalmente por combustibles fósiles que producen contaminantes atmosféricos con impactos directos en la salud de las poblaciones aledañas.
- En México, el crecimiento comercial ha traído beneficios económicos para las ciudades portuarias y las regiones aledañas; sin embargo, al mismo tiempo, han aumentado los riesgos a la salud, debido a la contaminación atmosférica por las operaciones portuarias.
- Ante las condiciones ambientales que afectan a los puertos y comunidades portuarias, la CGPMM ha previsto acciones encaminadas para la atención inmediata del Proceso de Descarbonización en el Sistema Portuario Nacional. En el Gobierno de México estamos conscientes que el proceso será largo, por lo resulta impostergable, con base en la EDP, comenzar con las medidas concretas con base en las siguientes consideraciones:

1. El Gobierno Federal, a través de las ASIPONAS y APIS, tiene la facultad y capacidad de optimizar el espacio físico y la infraestructura que faciliten proyectos y soluciones de energía alternativa sostenible.
2. El proceso de descarbonización comprende el desarrollo y cumplimiento de diferentes fases que comienzan con:

    - Planear el uso de los recursos del Sistema Portuario Nacional.

- Aplicar las líneas de acción definidas, siempre bajo una coordinación efectiva, y atendiendo la normatividad y directivas emitidas.
- Delimitar y el establecer de estándares que permitan la medición de los resultados obtenidos en periodos determinados y poder realizar los ajustes necesarios.

3. Para contribuir a lo anterior, se requiere promover la regulación necesaria que enmarque las acciones en los proyectos operativos de emisiones de bajo carbono, mejore los estándares ambientales, otorgue seguridad y certidumbre.
4. Los mandos medios y altos tienen la facultad y capacidad para gestionar, con los actores involucrados en las operaciones portuarias, la conformación de asociaciones y alianzas para compartir responsabilidades en la implementación de acciones específicas (atribución que requiere voluntad política).

Cabe mencionar que la EDP es impulsada a través de la CIMARES, debido a que es una instancia permanente cuyo objeto es coordinar las acciones de las dependencias y entidades de la Administración Pública Federal, relativas a la formulación e instrumentación de las políticas nacionales para la planeación, ordenación y desarrollo sustentable de los mares y las costas del territorio nacional. La transversalidad de CIMARES permitirá alcanzar mejores resultados en el proceso de consolidación de la EDP, en el marco de la Estrategia de Instrumentación para una Economía Oceánica Sostenible en México 2021-2024 (EIEOS).

La EDP está alineada con la EIEOS en dos acciones prioritarias:

1. Establecer e implementar reducciones de emisiones ambiciosas, que cubran a todos los sectores, con base en el objetivo del Acuerdo de París de perseguir esfuerzos para limitar los aumentos de temperatura mundiales a 1.5°C.
2. Utilizar soluciones basadas en la naturaleza, planificación y desarrollo de infraestructura costera para reducir la infraestructura gris e incentivar su uso para captar y almacenar carbono y mejorar la resiliencia costera.

4.2 Aspectos relevantes en la etapa de planeación

La EDP es el eje transversal que determinará la puesta en marcha de proyectos y acciones de mitigación y adaptación para la reducción de emisiones contaminantes y la consecución de los siguientes objetivos:

Objetivo general:

- Alcanzar un balance adecuado entre la actividad económica y la protección del medio ambiente en los puertos nacionales, favoreciendo el uso de combustibles limpios, con emisiones de carbono bajas o nulas, así como el desarrollo de infraestructura y tecnologías innovadoras que contribuyan a una gestión logística más eficiente y menos expuesta a interrupciones de las operaciones portuarias con el consecuente incremento en las condiciones ambientales y en la competitividad de nuestros puertos, que redunden en mejores condiciones comerciales de nuestro país.

Objetivos específicos:

1. Adoptar un enfoque sostenible en las inversiones en infraestructura portuaria a través de medidas de adaptación y respuesta al riesgo climático.
2. Reducir en el Sistema Portuario Nacional las emisiones generadas por las operaciones portuarias en cumplimiento a las metas internacionales y de carácter sectorial, **contribuyendo** a la meta nacional conforme a las siguientes previsiones:
    a. Reducción de emisiones de GEI (CO_2 equivalente) de 25% para 2030
    b. Reducción de emisiones de GEI (CO_2 equivalente) de 45% para 2050.

3. Actualizar el marco jurídico y administrativo de las ASIPONASy de las APIS en congruencia con las acciones previstas.

Para llevar a buen término los objetivos de la EDP es necesario establecer acciones específicas que permitan su ejecución sistemática y sistémica, dentro de un marco integrado de responsables y responsabilidades que son los que llevarán a cabo con cabalidad la ejecución y cumplimiento de cada acción estratégica que se formule. Por lo anterior, se propone:

1. Crear el Inventario de Emisiones Portuarias. Es una herramienta sistematizada que homologará, cuantificará e integrará los datos de los puertos y que permitirá generar reportes para la medición, evaluación y análisis de los resultados obtenidos, tanto en el puerto como a nivel central. Utilizando como apoyo la Guía n.º 1: Evaluación de las emisiones portuarias emitida por la OMI[3].
2. Identificar, definir y elaborar propuestas de soluciones operativas, medidas de adaptación y respuestas a la reducción de emisiones contaminantes para mejorar el cambio climático y que tengan implementación en el corto y mediano plazo.
3. Revisar el marco jurídico y administrativo del Sistema Portuario Nacional (ASIPONAS, API, puertos y terminales no concesionados) para adaptar y orientar el cumplimiento de los compromisos y responsabilidades a los requerimientos actuales.
4. Alinear los instrumentos de gobernanza y planeación tales como: Títulos de Concesión, Programas Maestros de Desarrollo Portuario, Reglas de Operación y, Programas Operativos Anuales en congruencia con los objetivos de la EDP.
5. Identificar, describir y programar la implementación de acciones para el uso de energías de bajas emisiones.
6. Identificar, describir y programar medidas operativas tales como: electrificación de equipo portuario (grúas, montacargas, vehículos, etc.), automatización de procesos administrativos y agilización de procesos de digitalización.
7. Implementar, dentro de la plataforma Puerto Inteligente Seguro (PIS), un módulo especializado denominado ECOPIS que permita registrar datos relevantes de manera integral y para todos los puertos sectorizados a la Secretaría de Marina y que estará coordinado por la CGPMM. El ECOPIS se conformará con base en el Greenhouse Gas Protocol (GHG) que es una metodología estandarizada para la medición y cálculo de emisiones GEI.
8. Planificar la infraestructura resiliente.

4.3 Implementación de acciones

En la búsqueda de soluciones para problemas complejos se requiere de la concertación de esfuerzos, recursos, responsables y responsabilidades; en suma, de equipos de trabajo multidisciplinarios e interinstitucionales, altamente competitivos, comprometidos y, sobre todo, estrictamente interrelacionados.

En tal sentido, con el propósito de establecer las bases de la EPD, la CGPMM en trabajo conjunto con las Direcciones Generales de las ASIPONAS Y APIS, específicamente, con las áreas de ecología, han realizado un trabajo colaborativo que permitió designar líderes en cada puerto, concientizar a los servidores públicos y tomadores de decisiones de las comunidades portuarias, así como la capacitación técnica para el Inventario de Emisiones Portuarias.

[3] El proyecto GloMEEP es una iniciativa conjunta del Fondo para el Medio Ambiente Mundial (FMAM), el Programa de las Naciones Unidas para el Desarrollo (PNUD) y la Organización Marítima Internacional (OMI) para asistir a los países en desarrollo en la incorporación e implementación de medidas de eficiencia energética para la industria marítima, con el objetivo de reducir las emisiones de gases de efecto invernadero y prevenir la contaminación atmosférica proveniente de buques.

En la etapa inicial, los responsables de cada ASIPONA definieron las características y habilidades, tanto internas como externas, para poner en marcha la EDP, así como las áreas de oportunidad para obtener mejores resultados.

Figura 1. Características, habilidades y áreas de oportunidad para la EDP.

Para la transición de la fase mecánica a la dinámica de la EDP, se elaboró una guía de acciones para 2022-2023, que resume las actividades relevantes con base en el alcance previsto:

Figura 2. Resumen de actividades relevantes.

Para concretar los esfuerzos es que se inició la elaboración de un inventario de emisiones:

5. *Inventario de Gases Efecto Invernadero del Sistema Portuario Nacional*

La medición y análisis de resultados de las emisiones contaminantes atmosféricas procedentes de fuentes portuarias constituye la base para la elaboración, desarrollo, adaptación y actualización de estrategias para la identificación e implementación de medidas de mitigación de GEI que contribuyan a la disminución y adaptación de efectos del cambio climático.

Por lo tanto, es imprescindible la conformación de un inventario de emisiones que permita, a través de un sistema integral de recopilación de datos provenientes de la operación portuaria, evaluar los factores de emisión específicos, los niveles de eficiencia y efectividad de las medidas adoptadas, así como determinar la asignación de recursos para la implementación de nuevos proyectos.

El inventario es un mecanismo de control del cuidado del aire y un marco de referencia para tomar las medidas necesarias para cumplir con las atribuciones establecidas en el artículo 7 de la Ley General de Cambio Climático; las indicadas por la Agenda 2030; la Estrategia inicial sobre la reducción de las emisiones de GEI procedentes de los buques emitida por la OMI, así como las determinadas por esta Coordinación. Como referencia para elaborar la base metodológica, se usó el: “Proyecto GFE-UNDP-IMO GloMEEP e IAPH, 2018: Herramientas para las emisiones portuarias, Guía N.°1, Evaluación de las emisiones portuarias”, que se describe a continuación:

Alcances del inventario

- Emisiones directas derivadas del consumo de energías fósiles (alcance 1).
- Emisiones indirectas derivadas del consumo (compra) de energía eléctrica que se utiliza para las operaciones de equipo e instalaciones portuarias (alcance 2).
- Emisiones procedentes de los buques, en los casos que aplique (alcance 3).

Límite organizacional

El inventario comprende la totalidad de las áreas que componen los recintos portuarios concesionados por el Gobierno Federal a las Administraciones Portuarias que conforman el Sistema Portuario Nacional, incluyendo sectorizadas y estatales.

Límite operacional

Todas las áreas comprendidas dentro de los límites del puerto, así como todos los cesionarios y permisionarios autorizados mediante contratos con las ASIPONAS y APIS. Asimismo, los prestadores de servicios que cuenten, para su operación en los puertos, con fuentes de emisiones de GEI tales como:

a) Vehículos para realizar tareas livianas, propiedad de la empresa o bajo arrendamiento.
b) Vehículos para realizar tareas pesadas, propiedad de la empresa o bajo arrendamiento.
c) Equipo de manipulación de la carga, propiedad de la empresa o bajo arrendamiento.
d) Transporte ferroviario.
e) Embarcaciones para servicios portuarios consignados en el artículo 44, fracción I, de la Ley de Puertos.
f) Calderas y hornos en edificios.
g) Cualquier otra fuente de emisión que posea y opere la empresa para la prestación de sus servicios.
h) Red eléctrica.
i) Plantas de energía.
j) Instalaciones industriales o de fabricación.
k) Oficinas administrativas.
l) Iluminación de accesos, áreas y vialidades.

5.1 Sistematización del Inventario de GEI

Los ejercicios preliminares realizados con los datos disponibles del ejercicio 2021 arrojaron resultados insuficientes; por tal motivo, se determinó el año 2022 como la línea base del Inventario de GEI del Sistema Portuario Nacional (Anexos 1 y 2).

Para la sistematización del inventario se creó el módulo denominado ECOPIS, dentro de la Plataforma Puerto Inteligente Seguro (PIS), que será usado como monitor de prueba para identificar el alcance y la pertinencia de los resultados logrados en su aplicación, poniendo énfasis en los resultados y las desviaciones detectadas con relación a los objetivos predeterminados, lo que permitirá corregir todas aquellas irregularidades encontradas en la operación de dicho módulo y una vez corregidas, o mejoradas, serán la base para la sistematización.

La CGPMM, a través de ASIPONA Manzanillo, analiza los procesos asociados para poder definir algoritmos propios, integrar a todas las ASIPONAS y contar con un tablero gerencial con los resultados. El módulo ECOPIS incluirá la información de los diferentes actores que intervienen en las operaciones portuarias. Con lo que podrá contar con un inventario de emisiones que considere, tanto las generadas por la administración del puerto, las terminales, instalaciones, prestadores de servicios y líneas navieras. Todo agrupado en un módulo de seguimiento a nivel nacional.

La conversión de un puerto convencional a un puerto cero emisiones netas implica poner en marcha acciones -de corto, mediano y largo plazo- que van desde lo administrativo hasta el cambio tecnológico y otras soluciones operativas, tales como: uso de energía renovable, electrificación de muelles, sistemas de autoconsumo con paneles solares y reforestación, así como gestión de residuos, medidas que promuevan el control de contaminación del aire, compromiso social con las partes interesadas, capacitación del personal, implementación de soluciones digitales y renovación tecnológica, entre otras.

Los puertos, y sus respectivas comunidades portuarias, han emprendido acciones acordes a su vocación; por ejemplo: las ASIPONAS y la API de Baja California Sur han contribuido a la identificación de 55 acciones (Anexos 3 y 4) de acciones orientadas a la reducción de emisiones, que han sido clasificadas según el impacto que tendrán en los alcances 1, 2 y 3. Cabe destacar que dichas acciones son ejecutadas según las capacidades de cada puerto.

Por su parte, para este 2024, la CGPMM está enfocando sus esfuerzos en el perfeccionamiento del inventario de emisiones para tener una medición en la huella de carbono fiable y congruente, además de fortalecer la colaboración con actores estratégicos mediante:

- Promover un mayor involucramiento de actores clave en el proyecto.
- Identificar acciones de terminales y prestadores de servicios que se alinean y coinciden con los objetivos de la EDP.
- Difundir, entre los actores pertinentes en las ASIPONAS, la EDP de México" (EDP).
- Planificar acciones para la reducción de emisiones tomando como base los elementos utilizados en el Inventario de Gases Efecto Invernadero del SPN.
- Acelerar los ajustes en las Reglas de Operación de Control de Emisiones de GEI y otras que se consideren oportunas para fortalecer la gobernanza de la Estrategia.
- Fortalecer la comunicación y el trabajo conjunto entre las gerencias y líderes del proyecto en cada puerto (áreas de ecología) para integrar correctamente las acciones programadas.
- Identificar y priorizar los proyectos de infraestructura portuaria en desarrollo y por desarrollar con enfoque sostenible para cumplir con las metas de reducción en toneladas de CO_2 equivalente de 25% para 2030 y 45% al 2050.

Asimismo, para 2024, se prevé contar con:

1. Programa de trabajo 2025: identificando metas de reducción de emisiones en los Alcances 1, 2 y 3, considerando como parámetro la reducción de 25% en las emisiones totales para 2030 (Anexo 1).
2. Hoja de ruta del SPN hacia el 2030 (acciones planeadas y su impacto en la meta reducción de 25% de las emisiones al año 2030).
3. Reporte de resultados obtenidos de la implementación de acciones de reducción de emisiones en cada puerto.
4. Resultados definitivos del Inventario de emisiones 2022 y 2023, en el Módulo ECOPIS.
5. Publicación del Anuario estadístico del Sistema Portuario Nacional 2023 con la información integrada del Inventario de emisiones.

Con esta herramienta sistematizada, el Sistema Portuario Nacional estará a la vanguardia en América Latina en medición y registro de la huella de carbono y será una herramienta útil para la instrumentación de políticas públicas.

6. Cambios en las Reglas de Operación de cada puerto

Como parte de las acciones emprendidas para fortalecer la gobernanza de la estrategia, se llevó a cabo la revisión de las Reglas de Operación en las ASIPONAS; en ésta, solo ASIPONA Manzanillo cuenta con una regla clara para el seguimiento de la calidad del aire. Por esta razón, se determinó necesario que las ASIPONAS alineen su contenido a los requerimientos en materia ambiental. Para ello, se parte del concepto de que las Reglas de Operación son un conjunto de disposiciones que regulan la operación de cada puerto y que contienen lo necesario para lograr los niveles de productividad, calidad, eficacia, seguridad en el embarque, desembarque y tránsito de personas, bienes y mercancías.

Dentro de este orden de ideas, y con el propósito de lograr que los puertos cuenten con una estructura homologada para el seguimiento y control de la estrategia de descarbonización y puedan contar con una herramienta de apoyo para solicitar e integrar la información requerida, la CGPMM diseñó una Regla de Operación "tipo" que contiene las especificaciones necesarias para la base de seguimiento de la estrategia en las ASIPONAS y que fueron difundidas por Dirección General de Puertos (DGP).

En consecuencia, en diciembre 2023, la DGP emitió el *Oficio No. DGP. -4856.2023* para que cada puerto, en el ámbito de su competencia, integre en sus respectivas Reglas de Operación, la estructura para el ***Control de las Emisiones de Gases de Efecto Invernadero y Partículas Suspendidas*** de acuerdo con las siguientes especificaciones:

1. Normatividad aplicable del control de la contaminación del aire.
2. Límite organizacional. Área concesionada por el Gobierno Federal a la ASIPONA.
3. Límite operacional. Aplicable a todas las áreas comprendidas dentro de los límites del puerto, aplica para todos los cesionarios y permisionarios con los que la ASIPONA tenga firmado contrato, así como a prestadores de servicios que utilicen para su operación alguna fuente de emisiones de Gases de Efecto Invernadero (GEI).
4. De las responsabilidades en el proceso de integración del inventario de GEI del puerto. Refiere las particularidades técnicas y de comunicación para la integración del inventario de emisiones.
5. Inventario del equipamiento portuario.
6. Informe anual de emisiones de GEI (bióxido de carbono equivalente) generadas en el año inmediato anterior.
7. Plan de prevención y control de la contaminación del aire por emisiones de fuentes fijas y móviles. Será entregado dentro de los primeros 45 días naturales al inicio de cada año al Administrador Portuario y deberá contener al menos la siguiente información:

    a. Programa de Mantenimiento preventivo de vehículos automotores.
    b. Programa de Mantenimiento preventivo por horas de equipos móviles.
    c. Programa de Mantenimiento de las instalaciones eléctricas.
    d. Programa de acciones adoptadas y por adoptar que contribuyan a la reducción de GEI y huella de carbono (soluciones medioambientales y equipamiento que promueva la transición energética).

Asimismo, en el plan de prevención y control de la contaminación del aire por emisiones de fuentes fijas y móviles, se deberán incluir acciones necesarias de compensación para mitigar las emisiones de GEI generadas indirectamente por el usuario, así como para la evaluación de las emisiones generadas en el recinto portuario y contribuir a su disminución. De acuerdo con lo establecido en el artículo 84 del Reglamento de la Ley de Puertos, las Reglas de Operación de cada puerto y sus modificaciones deberán someterse a la autorización de la Secretaría, previa opinión de sus respectivos Comités de Operación. Por su parte, la DGP consideró un máximo de seis meses para la implementación de dicha Regla, por lo que el límite será junio de 2024 (oficio DGP.-4856.2023).

Por último, en función de lo planteado, resulta inobjetable que aún queda mucho por hacer en la ardua labor que implica el poner en marcha acciones efectivas en el ámbito portuario para la reducción de emisiones de contaminantes.

7. Conclusiones

El problema de la emisión de GEI y cualquier otro tipo de emisiones contaminantes es prioritario atender, ya que ocasionan un gran deterioro ambiental.

Nuestro país ha suscrito acuerdos internacionales que tratan el combate al cambio climático, causado por el uso inadecuado de las tecnologías extractivas, los procesos industriales que toman a la ligera esta problemática y no invierten en la prevención, control e impedimento de los procesos contaminantes en nuestros ríos, mares, lagunas, esteros y demás ecosistemas marítimos, terrestres y aéreos; en general, en nuestros recursos naturales, responsabilidad del Estado Mexicano.

Las autoridades tenemos que actuar en forma coordinada y decidida, lejos de intereses particulares, bajo un mismo principio democrático, técnico y científico que unifique propuestas de diferentes sectores: instituciones científicas, académicas, tanto públicas como privadas y población civil, auspiciado desde una plataforma integral como es Plan Nacional de Desarrollo, los Planes Estatales y los Programas rectores de desarrollo de cada entidad y dependencias del Estado.

Las acciones que se presentan constituyen el punto de partida de la EDP de México, pero requerirá de un análisis que logre convertirla en la estrategia deseada para resolver la problemática descrita en los puertos mexicanos. Se debe de insistir en la necesidad de que la visión estratégica sea incluyente; en otras palabras, se trata de estrategias generales de un plan integral que derivará en acciones en los planes de cada puerto.

Es el momento ineludible de hacerlo. México tiene un compromiso para reducir las emisiones generadas por las operaciones portuarias en el Sistema Portuario Nacional, en cumplimiento a las metas internacionales y de carácter sectorial. Por el bien de todos es necesario luchar y ganar la batalla contra la contaminación de nuestros recursos naturales, buscando ayuda en las tecnologías limpias que detengan el deterioro e, inclusive, y de ser irreversible, se debe pugnar por detener, crear y conservar nuevos y mejores procesos y procedimientos industriales que satisfagan condiciones de eficacia y eficiencia tanto administrativa como operativa, brindando los mejores resultados. El Estado debe articular, de manera democrática y efectiva, la política ambiental.

Para los puertos mexicanos es importante enfocar la problemática desde planes y programas que deben integrarse en un solo “plan global para reducir la huella de carbono” y, a partir de este, derivar planes específicos para cada puerto, bajo la coordinación y seguimiento puntual de las respectivas y correspondiente ASIPONAS y APIS que, en definitiva, son las responsables de llevar a cabo las estrategias planteadas en el combate al cambio climático.

Siglas y abreviaturas

- API: Administración Portuaria Integral.
- ASIPONA: Administración del Sistema Portuario Nacional.
- CGPMM: Coordinación General de Puertos y Marina Mercante.
- CMNUCC: Convención Marco de las Naciones Unidas sobre el Cambio Climático.
- CO_2eq: Dióxido de carbono equivalente.
- DGP: Dirección General de Puertos.
- EDP: Estrategia de Descarbonización de Puertos
- MEPC: Comité de Protección del Medio Marino.
- NDC (Nationally Determined Contributions): contribuciones determinadas a nivel nacional.
- OMI: Organización Marítima Internacional.
- ONU: Organización de las Naciones Unidas.
- SPN: Sistema Portuario Nacional.

Términos y Definiciones

- **Emisión:** Liberación a la atmósfera o al mar de sustancias sometidas a control, por los buques.

- **Emisiones antropogénicas:** Generación de emisiones GEI de larga permanencia por las actividades humanas: CO2, metano (CH4), óxido nitroso (N2O) y halocarbonos (gases que contienen flúor, cloro o bromo).
- **El equivalente de CO2 o equivalente de dióxido de carbono** (CO_2eq o Carbon Dioxide Equivalent, en inglés). Medida en toneladas de la huella de carbono.
- **Huella de carbono.** Nombre dado a la totalidad de la emisión de gases de efecto invernadero. La masa de los gases emitidos es medida por su equivalencia en CO2 (dióxido de carbono). El CO2 es el más conocido y es también la referencia del resto de los gases de efecto invernadero, a los que se considera causantes del calentamiento del planeta.

Anexo 3. Acciones identificadas en los Planes estratégicos de reducción en las ASIPONAS y API Baja California Sur al cierre de 2023

No.	Alcances de impacto/ Acción	Puertos que implementaran la acción	% de participación de los puertos
	Impacto en los Alcances 1,2 y 3	**6**	
1	Diagnóstico: Impulsando la Descarbonización del Sector Marítimo - Portuario en México, con un enfoque en el Puerto de Manzanillo	Manzanillo	6%
2	Publicación de la Regla de Operación de Calidad el aire.	Las 16 ASIPONAS y API Baja California Sur	100%
3	Monitoreo de las emisiones totales de ASIPONA, cesionarios y embarcaciones.	Las 16 ASIPONAS y API Baja California Sur	100%
4	Concientización de la comunidad portuaria sobre impacto de las emisiones de GEI.	Baja California Sur, Coatzacoalcos Dos Bocas, Ensenada, Guaymas Lázaro Cárdenas, Manzanillo, Progreso, Puerto Chiapas, Puerto Vallarta, Salina Cruz, Topolobampo y Tuxpan	76%
5	Elaboración material de concientización para la comunidad portuaria sobre impacto de las emisiones de GEI.	Dos Bocas, Progreso Puerto Vallarta, Salina Cruz y Topolobampo	29%
6	Elaboración e integración de un módulo en el sistema Puerto Inteligente Seguro "ECOPIS".	Manzanillo	6%
	Impacto en Alcance 1	**21**	
7	Cambio de luminarias.	Coatzacoalcos, Guaymas Lázaro Cárdenas, Manzanillo, Puerto Chiapas y Veracruz	35%
8	Mejoras y optimización en el tratamiento de residuos (reciclaje) con un enfoque de economía circular.	Coatzacoalcos, Dos Bocas, Mazatlán, Progreso y Puerto Chiapas	35%
9	Implementación de paneles solares.	Coatzacoalcos, Ensenada, Manzanillo, Puerto Vallarta, Veracruz	29%
10	Programa de reforestación de mangle.	Altamira, Baja California Sur, Coatzacoalcos, Lázaro Cárdenas y Veracruz	29%
11	Programa de reforestación.	Altamira, Dos Bocas, Puerto Chiapas, Puerto Vallarta y Salina Cruz	29%
12	Monitoreo del consumo de energía en las instalaciones de la entidad.	Dos Bocas, Manzanillo, Mazatlán y Puerto Chiapas	24%
13	Mantenimiento a Luminarias.	Guaymas, Manzanillo, Topolobampo y Tuxpan	24%
14	Integración en el Programa Sistema de Gestión Ambiental (SGA).	Dos Bocas, Manzanillo y Puerto Chiapas	18%
15	Mantenimiento de Vehículos.	Guaymas, Progreso y Tuxpan	18%
16	Mantenimiento de subestación Eléctrica.	Guaymas y Tuxpan	12%
17	Obtener la Certificación de Calidad Ambiental otorgada por PROFEPA.	Dos Bocas y Ensenada	12%
18	Recorridos a las Cesionarias del Puerto.	Veracruz	6%

No.	Alcances de impacto/ Acción	Puertos que implementaran la acción	% de participación de los puertos
19	Estudios de calidad del aire dentro de los límites del recinto portuario.	Lázaro Cárdenas	6%
20	Planes de Mantenimiento para los generadores de emergencias.	Manzanillo	6%
21	Dotación de infraestructura portuaria Suministro de ER.	Ensenada	6%
22	Construcción de una estación de monitoreo atmosférico TR.	Ensenada	6%
23	Sistematización de los procesos de monitoreo de HC.	Ensenada	6%
24	Indicadores de seguimiento de las medidas implementadas que den cuenta de la reducción de emisiones de Gases Efecto Invernadero, como el dióxido de carbono CO2, o de contaminantes criterio como el material pm 2.5 y pm 10.	Lázaro Cárdenas	6%
25	Verificar usos del puerto en el PMDP y correlacionarlos con alcances del Proyecto de Descarbonización en Puertos.	Dos Bocas	6%
26	Plan de reducción de consumo de gasolina por Diesel.	Guaymas	6%
27	Mantenimiento y limpieza de paneles Solares.	Guaymas	6%
	Impacto en Alcance 2	**18**	
28	Mantenimiento / Reemplazo de aires acondicionados.	Guaymas, Lázaro Cárdenas, Manzanillo, Progreso, Tuxpan y Veracruz	41%
29	Reducción de desechos de contenedores de un solo uso de alimentos en la comunidad portuaria.	Baja California Sur, Dos Bocas, Manzanillo y Puerto Chiapas	24%
30	Prevención en la dispersión de polvos por manejo de carga.	Lázaro Cárdenas	6%
31	Cambio de condensadores.	Manzanillo	6%
32	Bandas trasportadoras cerradas para evitar las emisiones de polvo creadas por la termoeléctrica utiliza como energético primario el carbón.	Manzanillo	6%
33	Sistema de automatización de equipos de refrigeración.	Topolobampo	6%
34	Estudios de opacidad.	Manzanillo	6%
35	Montacargas eléctricos.	Manzanillo	6%
36	Oficinas administrativas nuevas con eficiente sistema de iluminación para reducción de consumos de energía eléctrica.	Guaymas	6%
37	Bandas trasportadoras cerradas para evitar las emisiones de polvo creadas por el granel agrícola.	Manzanillo	6%
38	Identificación de almacenes frigorífico.	Guaymas	6%
39	Renovación de tracto camiones.	Manzanillo	6%
40	Inversión de grúas ecoeficientes.	Ensenada	6%
41	Uso de catalizador e implementación.	Manzanillo	6%
42	Uso de montacargas de GLP.	Manzanillo	6%

No.	Alcances de impacto/ Acción	Puertos que implementaran la acción	% de participación de los puertos
43	Vialidades externas.	Guaymas	6%
44	Banco de capacitores para la reducción de consumo de energía eléctrica.	Manzanillo	6%
45	Medidas correctivas conforme a los estudios de opacidad.	Manzanillo	6%
	Impacto en Alcance 3	**11**	
46	Análisis de la viabilidad de suministro eléctrico a buques.	Ensenada, Manzanillo, Tuxpan y Lázaro Cárdenas	24%
47	Impulso al cabotaje como alternativa para el transporte de mercancías como alternativa al transporte terrestre.	Dos Bocas, Manzanillo, Topolobampo y Veracruz	24%
48	Mantenimiento de infraestructura portuaria.	Guaymas y Topolobampo	12%
49	Dragado de Mantenimiento.	Tuxpan	6%
50	Dragado de Construcción.	Guaymas	6%
51	Remoción en el Agua de Bio incrustaciones Adheridas a la obra viva de los buques.	Tuxpan	6%
52	Reducción del uso de combustibles fósiles en equipos fijos de carga y móviles de movimiento y transporte de carga.	Manzanillo	6%
53	Construcción de Torre de Control de Tráfico Marítimo.	Tuxpan	6%
54	Vialidad del Libramiento Portuario a cuatro carriles.	Tuxpan	6%

Anexo 4. Acciones en cada puerto

Puerto	Acción	Alcance	Ejecución	Avances
Altamira	Programa de reforestación	1	2023	n.d.
Altamira	Programa de reforestación de mangle	1		n.d.
Altamira	Aportaciones para la elaboración de los lineamientos para la Regla de Operación de calidad del aire	1,2 y 3	2024	Se realizó el diagnóstico
Altamira	Monitoreo de las emisiones totales de ASIPONA, cesionarios y embarcaciones	1,2 y 3		n.d.
Baja California Sur	Programa de reforestación de mangle	1		n.d.
Baja California Sur	Reducción de desechos de contenedores de un solo uso de alimentos en la comunidad portuaria	2	Trimestral	n.d.
Baja California Sur	Publicación de la Regla de Operación de Calidad el aire	1,2 y 3	2024	Se realizó el diagnóstico
Baja California Sur	Concientización de la comunidad portuaria sobre impacto de las emisiones de GEI	1,2 y 3	Trimestral	n.d.
Baja California Sur	Monitoreo de las emisiones totales de ASIPONA, cesionarios y embarcaciones	1,2 y 3		n.d.
Coatzacoalcos	Cambio de luminarias	1		n.d.
Coatzacoalcos	Implementación de paneles solares	1		n.d.
Coatzacoalcos	Programa de reforestación de mangle	1		n.d.
Coatzacoalcos	Mejoras y optimización en el tratamiento de residuos (reciclaje) con un enfoque de economía circular	1	Semestral	n.d.
Coatzacoalcos	Publicación de la Regla de Operación de Calidad el aire	1,2 y 3	2024	Se realizó el diagnóstico
Coatzacoalcos	Concientización de la comunidad portuaria sobre impacto de las emisiones de GEI	1,2 y 3	Bimestral	n.d.
Coatzacoalcos	Monitoreo de las emisiones totales de ASIPONA, cesionarios y embarcaciones	1,2 y 3		n.d.
Dos Bocas	Verificar usos del puerto en el PMDP y correlacionarlos con alcances del Proyecto	1		n.d.

Puerto	Acción	Alcance	Ejecución	Avances
	de Descarbonización en Puertos			
Dos Bocas	Obtener la Certificación de Calidad Ambiental otorgada por PROFEPA	1	2024	Se da continuidad a la Certificación Ambiental y al plan de acción en la plataforma del SAAEL de la PROFEPA, que tiene 61% de avance del Plan de Acción y 37% del seguimiento en la plataforma.
Dos Bocas	Integración en el Programa SGA Sistema de Gestión Ambiental	1		Se cuenta con un SGA que cuenta con una política ambiental, así como con procesos, procedimientos y registros documentados, y se continúa con la mejora del SGI con la finalidad de proteger el medio ambiente, así como la mitigación de los impactos ambientales producidos por la operación portuaria.
Dos Bocas	Monitoreo del consumo de energía en las instalaciones de la entidad	1		n.d.
Dos Bocas	Programa de reforestación	1	2023 - 2024	Seguimiento y monitoreo del crecimiento de los guayacanes amarillos reforestados en la Terminal de Usos Múltiples
Dos Bocas	Mejoras y optimización en el tratamiento de residuos (reciclaje) con un enfoque de economía circular	1		Recolección de las tapitas que serán donadas a la fundación de niños con cáncer (oncopekes); están por ser entregadas.
Dos Bocas	Reducción de desechos de contenedores de un solo uso de alimentos en la comunidad portuaria	2		Se continúa con la campaña “Adiós plásticos de un solo uso”, difundida a: cesionarios, contratistas de obra, prestadores de servicios específicos y, de servicios portuarios para disminuir el ingreso de plástico al recinto portuario.
Dos Bocas	Impulso al cabotaje como alternativa para el transporte de mercancías como alternativa al transporte terrestre	3		Se gestionó la solicitud de suficiencia presupuestal para contratar la MIA (Manifestación de Impacto Ambiental), al igual que se han gestionado cotizaciones. Se elaboraron los Términos de Referencia para la contratación del servicio de la elaboración de la Manifestación de Impacto Ambiental y los Términos de Referencia del Estudio de la Vegetación Bentónica y de la flora y fauna terrestre.
Dos Bocas	Publicación de la Regla de Operación de Calidad el aire	1,2 y 3	2024	Se realizó el diagnóstico
Dos Bocas	Concientización de la comunidad portuaria sobre impacto de las emisiones de GEI	1,2 y 3		Difusión, mediante correo, de acciones para contribuir a la mejora de la calidad del aire.
Dos Bocas	Elaboración material de concientización para la comunidad portuaria sobre	1,2 y 3		Su publicación y difusión fue el 11/08/23 día interamericano de la calidad del aire

Puerto	Acción	Alcance	Ejecución	Avances
	impacto de las emisiones de GEI			
Dos Bocas	Monitoreo de las emisiones totales de ASIPONA, cesionarios y embarcaciones	1,2 y 3		El Puerto de Dos Bocas se destaca por su excelente ubicación geográfica, ya que brinda conectividad inmediata con la Terminal de abastecimiento de Pemex y la Refinería olmeca, siendo las principales fuentes de emisiones de GEI
Ensenada	Obtener la Certificación de Calidad Ambiental otorgada por PROFEPA	1	2024	En espera de resultados en febrero/marzo de 2024
Ensenada	Implementación de paneles solares	1		Proveedor Externo
Ensenada	Construcción de una estación de monitoreo atmosférico TR	1		n.d.
Ensenada	Dotación de infraestructura portuaria Suministro de ER	1		n.d.
Ensenada	Sistematización de los procesos de monitoreo de HC	1		n.d.
Ensenada	Inversión de grúas ecoeficientes	2		n.d.
Ensenada	Análisis de la viabilidad de suministro eléctrico a buques	3		n.d.
Ensenada	Publicación de la Regla de Operación de Calidad el aire	1,2 y 3	2024	Se realizó el diagnóstico
Ensenada	Concientización de la comunidad portuaria sobre impacto de las emisiones de GEI	1,2 y 3	Trimestral	Reporte trimestral de consumo

Lázaro Cárdenas	Estudios de calidad del aire dentro de los límites del recinto portuario.	1		FERTINAL (AGROINDUSTRIAS DEL BALSAS S.A. DE C.V) realiza estudios de calidad del aire estando dentro de LMP de contaminante, así mismo cuenta con túneles, con sistema de agua para humedecer la roca, en las transferencias de las bandas, con el objetivo de evitar los polvos fugitivos durante la descarga. ARCELOR MITTAL. Realiza monitoreo de calidad del aire de acuerdo con la NOM-025- SSA1-2014, Salud ambiental. Valores límite permisibles para la concentración de partículas suspendidas PM10 y PM2. 5 en el aire ambiente y criterios para su evaluación, especificó como valores de concentración promedio de 24 horas, cumpliendo con los LMP de contaminantes.

Veracruz	Recorridos a las cesionarias del puerto	1	Trimestral	Se avanza conforme al programa entre los meses de mayo a julio, 47%. Se han visitado a las terminales de la bahía norte: ESJ Renovable, ICAVE, OPEVER, PETRA, de la bahía sur CICE, SEMAVE, TMV, TNG, TCE, supervisando que los alcances: tipo de energía, refrigerantes y suministro de CFE coincidan con lo reportado. Se verifica las condiciones del equipo de maniobristas, en lo que va del año no presentan ninguna incidencia ambiental.
Veracruz	Cambio de luminarias	1	15/05/2023	Se instalaron 95 luminarias Leds, avanzando 6%, quedando en total en 58% de luminarias Leds reduciéndose en 42% el número por sustituir en el puerto.
Veracruz	Implementación de paneles solares.	1	15/05/2023	Comienza en septiembre 2023 5.1. Producción anual de 30,000 plantas de mangle.
Veracruz	Programa de reforestación de mangle	1	12/05/23 mantener el programa de la zona de conservación Selva Mediana	Se cumple con la producción programada de mangle en Punta Gorda llegando a un 70%.
Veracruz	Mantenimiento / Reemplazo de aires acondicionados	2	15/05/2023	Para 2023 está programado sustituir 55 equipos de aire acondicionado tipo inverter; ya se han remplazado 47 equipos; 85% del presupuestado para este rubro en 2023. Esto representa 12% de avance en el cambio total de los equipos que utilizan R-22 y están expuesto a emitir gases de efecto invernadero por el tipo de refrigerante
Veracruz	Impulso al cabotaje como alternativa para el transporte de mercancías como alternativa al transporte terrestre	3	12/05/2023 están disponibles,	Se ha avanzado 14.3% al rentarse el área E12B-2 a la empresa CEMEX, S.A. de C.V.
Veracruz	Publicación de la Regla de Operación de Calidad el aire	1,2 y 3	2024	Se realizó el diagnóstico
Veracruz	Monitoreo de las emisiones totales de ASIPONA, cesionarios y embarcaciones	1,2 y 3	Del 26 de mayo al 15 de diciembre	Se actualiza su inventario incluyendo el alcance 3 puerto en diciembre

Antecedentes

El Puerto de Manzanillo, junto con el Puerto Laguna de Cuyutlán, se localiza en el litoral del Océano Pacífico, en el estado de Colima, constituyendo uno de los principales nodos logísticos del comercio exterior de México. Su ubicación geográfica estratégica, así como su conectividad terrestre y marítima, le confieren un papel fundamental en la articulación de las cadenas de suministro entre Asia y la región centro-occidente del país.

De acuerdo con el PMDP (Programa Maestro de Desarrollo Portuario) el Puerto de Manzanillo se caracteriza por su vocación predominantemente comercial, con una alta especialización en el manejo de carga contenerizada, lo que lo posiciona como el principal puerto del país en este segmento, concentrando una proporción significativa del movimiento nacional de contenedores. Esta especialización se sustenta en su infraestructura portuaria, su capacidad instalada y la eficiencia operativa de sus terminales, que permiten atender cargas de gran escala y altos volúmenes de operación.

Adicionalmente, el puerto cuenta con una diversificación operativa que incluye el manejo de granel mineral, granel agrícola, carga general, hidrocarburos, vehículos, pesca y cruceros, lo que refuerza su papel como un puerto multipropósito dentro del sistema portuario nacional. Esta diversidad de líneas de negocio genera una dinámica compleja de tráfico marítimo, al coexistir distintos tipos de buques con requerimientos operativos diferenciados.

En relación con el "ACUERDO Secretarial 503/2023, por el cual se establece la jurisdicción territorial y marítima de las Capitanías de Puerto.", publicado en el Diario Oficial de la Federación, Manzanillo es una Capitanía de Puerto Regional y en su jurisdicción territorial incluye la Laguna de Cuyutlán la cual se orienta principalmente al manejo de energéticos, particularmente gas natural licuado e hidrocarburos, y se proyecta como una zona de expansión para la atención de buques de mayor dimensión, que no pueden ser operados en el puerto de Manzanillo debido a limitaciones físicas en canales y dársenas.

En términos de infraestructura y operación, el sistema portuario dispone de áreas de navegación, fondeo y atraque, así como de un sistema de señalamiento marítimo y control de tráfico alineado a estándares internacionales, destacando el Centro de Control de Tráfico Marítimo (CCTM), el cual tiene como función coordinar el tránsito de embarcaciones, garantizar la seguridad de la navegación y contribuir a la protección del medio ambiente marino.

La zona de influencia del puerto abarca regiones estratégicas del país, incluyendo el Valle de México, el Bajío-occidente y el norte industrial, lo que genera una alta

demanda de servicios portuarios y un flujo constante de embarcaciones, consolidando al puerto como un punto clave para el comercio internacional y el transbordo regional.

En el marco del desarrollo portuario proyectado en la Laguna de Cuyutlán, se ha identificado la necesidad de evaluar las posibles afectaciones asociadas a la operación de buques porta-contenedores de gran capacidad, particularmente aquellos superiores a 20,000 TEUs. En este contexto, la Administración del Sistema Portuario Nacional Manzanillo (ASIPONA Manzanillo) ha encomendado a Eco Port la elaboración del estudio **"ESTUDIO DE TRAFICO MARINO CON EL FIN DE GESTIONAR EL MOVIMIENTO DE BUQUES, PARA GARANTIZAR LA SEGURIDAD, EFICIENCIA LOGISTICA Y PROTECCIÓN AMBIENTAL DE LA LAGUNA DEL VASO II EN EL NUEVO PUERTO LAGUNA DE CUYUTLAN."** cuyo objetivo es analizar las condiciones de tráfico marítimo y sus implicaciones operativas y ambientales en la zona.

Este estudio puede servir parcialmente para los siguientes rubros:

1. Proporcionalmente para la elaboración de las reglas de operación de las terminales situadas en la Laguna Cuyutlán denominada “Nuevo Puerto Manzanillo”.
2. En su parte proporcional y en lo conducente para la elaboración de la MIA correspondiente en lo que respecta a volúmenes de dragado necesarios para alcanzar una operación óptima en las nuevas terminales que se instalarán en la Laguna de Cuyutlán, así como las medidas que se recomienden en las conclusiones derivadas de los anexos I a VI de MARPOL.
3. Parcialmente como insumo para el estudio de maniobrabilidad de acuerdo al dimensionamiento de embarcaciones mayores y el claro de la quilla necesario para garantizar la seguridad de la navegación.
4. Pudiese servir como insumo parcial para la elaboración de análisis FODA requeridos en diversos estudios.
5. Entre otros.

En atención a lo anterior, se desarrolla el presente documento, que se estructura en tres componentes principales, orientados a analizar de manera integral las condiciones del tráfico marítimo asociadas al desarrollo del Proyecto Nuevo Cuyutlán, así como sus implicaciones operativas y ambientales.

En primer término, se desarrolla el análisis de la flota mundial de buques porta-contenedores, incluyendo su evolución, categorización y características operativas relevantes, con especial énfasis en aquellas embarcaciones de gran capacidad superiores a 20,000 TEUs. Asimismo, se evalúa la compatibilidad de dicha flota con las condiciones físicas y operativas del proyecto portuario de Cuyutlán, considerando parámetros tales como calado, eslora, manga y requerimientos de seguridad conforme a recomendaciones internacionales.

Posteriormente, se analizan las condiciones de tráfico marítimo, tanto actuales en el Puerto de Manzanillo como proyectadas para Cuyutlán, incorporando comparativos con puertos de referencia a nivel mundial. Este análisis incluye la evaluación de rutas de tránsito, tiempos de maniobra y patrones de navegación, a partir de información histórica de tráfico marítimo.

Finalmente, se aborda la evaluación operativa y ambiental del tráfico marítimo, integrando la opinión de expertos, el análisis del sistema de control de tráfico marítimo (VTS - *Vessel Traffic System*), así como la revisión de criterios normativos aplicables. Con base en lo anterior, se identifican los posibles impactos asociados a la operación de buques de gran escala, particularmente en materia de ruido submarino y su interacción con el entorno marino.

Como resultado, el estudio culmina con la formulación de recomendaciones orientadas a la adecuación de las reglas de operación del puerto, con el objetivo de mitigar los efectos identificados y facilitar una operación segura, eficiente y ambientalmente responsable.

1. Flota mundial de buques porta contenedores

Introducción

De acuerdo con el informe "Container Intelligence Quarterly" de Clarksons Research del primer trimestre de 2026, a la fecha de la publicación, existen 7,048 buques porta-contenedores a nivel mundial. Esta flota forma parte de un sistema marítimo altamente dinámico, caracterizado por un crecimiento sostenido en capacidad y una evolución constante hacia embarcaciones de mayor tamaño.

En términos de capacidad, la flota mundial de buques porta-contenedores ha alcanzado aproximadamente 32.3 millones de TEUs, con tasas de crecimiento anual del orden de 6 a 7%, impulsadas principalmente por la incorporación de nuevas unidades principalmente en el rango de 12,000 a 17,000 TEUs (Neo-Panamax) y una prácticamente nula tasa de desguace en el último año (8 unidades). Se espera otro año de crecimiento sólido (~5%) en 2026, lo que implicaría que la flota a finales de 2026 sea aproximadamente 33% mayor que a inicios de 2023.

Asimismo, se observa una tendencia clara hacia la concentración de flota en segmentos de mayor tamaño, destacando los buques tipo Post-Panamax (de

17,000 TEUs o más) cuya operación se ha consolidado principalmente en las principales rutas comerciales Este-Oeste. Sin embargo, en años recientes se han identificado cambios en los patrones de despliegue, con estas unidades incursionando en rutas no tradicionales, lo que refleja una mayor flexibilidad operativa del mercado marítimo.

Desde el punto de vista del comercio marítimo, el transporte de contenedores continúa mostrando resiliencia, con tasas de crecimiento global cercanas al 3% este año, a pesar de condiciones geopolíticas variables y ajustes en las cadenas logísticas internacionales. Esta dinámica ha generado una presión constante sobre la infraestructura portuaria.

En este contexto, el análisis de la flota mundial de buques porta-contenedores resulta fundamental para el presente estudio, ya que permite establecer las características operativas, dimensiones y requerimientos de las embarcaciones que potencialmente podrían operar en el Proyecto Nuevo Cuyutlán, así como dimensionar las implicaciones en términos de infraestructura, maniobrabilidad y condiciones de tráfico marítimo.

1.1. Categorización de la flota mundial de contenedores

De acuerdo con el reporte "Shipping Review and Outlook, Liners" del 1er trimestre del 2026 de Clarksons Research, el mercado del transporte de contenedores ha presentado comportamientos divergentes durante el año, caracterizado por una alta volatilidad en las tarifas de flete, influenciada principalmente por factores geopolíticos. En este sentido, las tarifas han mostrado una tendencia a la baja respecto a los niveles elevados observados en 2024, alcanzando valores cercanos a los registrados antes de la disrupción en el Mar Rojo. En contraste, el mercado de fletamento ha mostrado una tendencia al alza, con incrementos sostenidos en las tarifas de alquiler de buques debido a la limitada disponibilidad de embarcaciones y a una demanda firme.

En particular, las rutas transpacíficas experimentaron incrementos temporales derivados de acuerdos comerciales, mientras que otras rutas, como Extremo Oriente–Europa, mostraron recuperación temporal seguida de ajustes por exceso de capacidad y competencia entre navieras.

Por su parte, las tarifas de fletamento de buques porta-contenedores han continuado aumentando, alcanzando niveles elevados en todos los segmentos de tamaño. Este comportamiento se explica por la escasez de buques disponibles, así como por la práctica de contratación anticipada por parte de los operadores. Asimismo, los periodos de contratación se han extendido, reflejando una mayor necesidad de asegurar capacidad a mediano plazo.

En cuanto a la flota mundial, esta ha continuado creciendo de manera sostenida, alcanzando aproximadamente 32.3 millones de TEUs, impulsada por la entrega constante de nuevas embarcaciones, especialmente en el segmento de 12,000 a 17,000 TEUs, y por una actividad de desguace prácticamente inexistente. Se estima un crecimiento anual de la flota entre 6% y 7%, con proyecciones de crecimiento adicional en los próximos años.

Respecto a la contratación de nuevos buques, se observa un ritmo elevado de pedidos, cercano a niveles récord, con una fuerte concentración en los segmentos de mayor capacidad, aunque también se ha registrado un repunte en la demanda de buques de menor tamaño tipo feeder.

El crecimiento del comercio de contenedores ha sido impulsado principalmente por el incremento en las exportaciones provenientes de Asia, las cuales han compensado la desaceleración observada en otras rutas comerciales. Este dinamismo ha permitido mantener una tendencia positiva en el volumen global transportado, a pesar de la incertidumbre derivada de factores geopolíticos y ajustes en las políticas comerciales internacionales. En este contexto, se estima que el comercio mundial de contenedores registre una tasa de crecimiento cercana al 3% anual, reflejando una recuperación moderada y sostenida en la demanda de transporte marítimo.

En términos de la estructura de la flota, los buques de gran capacidad, particularmente aquellos con capacidades superiores a 17,000 TEUs, continúan siendo desplegados principalmente en las rutas principales, como la que conecta el Extremo Oriente con Europa. No obstante, se han observado cambios en sus patrones de despliegue, incluyendo su utilización en rutas no tradicionales, como las que conectan el Extremo Oriente con África. Por su parte, los buques de capacidad intermedia y menor siguen desempeñando un papel importante en rutas regionales, así como en servicios norte-sur e intrarregionales.

Finalmente, se prevé que las condiciones del mercado enfrenten presiones como resultado del crecimiento de la flota a un ritmo superior al de la demanda, así como de la posible normalización de las rutas marítimas que actualmente se encuentran afectadas por disrupciones geopolíticas, lo cual podría tener un impacto tanto en las tarifas de flete como en la dinámica operativa del sector.

De acuerdo con el reporte "*Container Intelligence Quarterly*" del 1er trimestre del 2026 de *Clarksons Resarch*, hoy en día la flota mundial de buques porta-contenedores se divide en 4 tipos de embarcaciones: Feeder, Intermediate, Neo-Panamax y Post-Panamax, clasificadas por rangos de capacidad en TEUs.

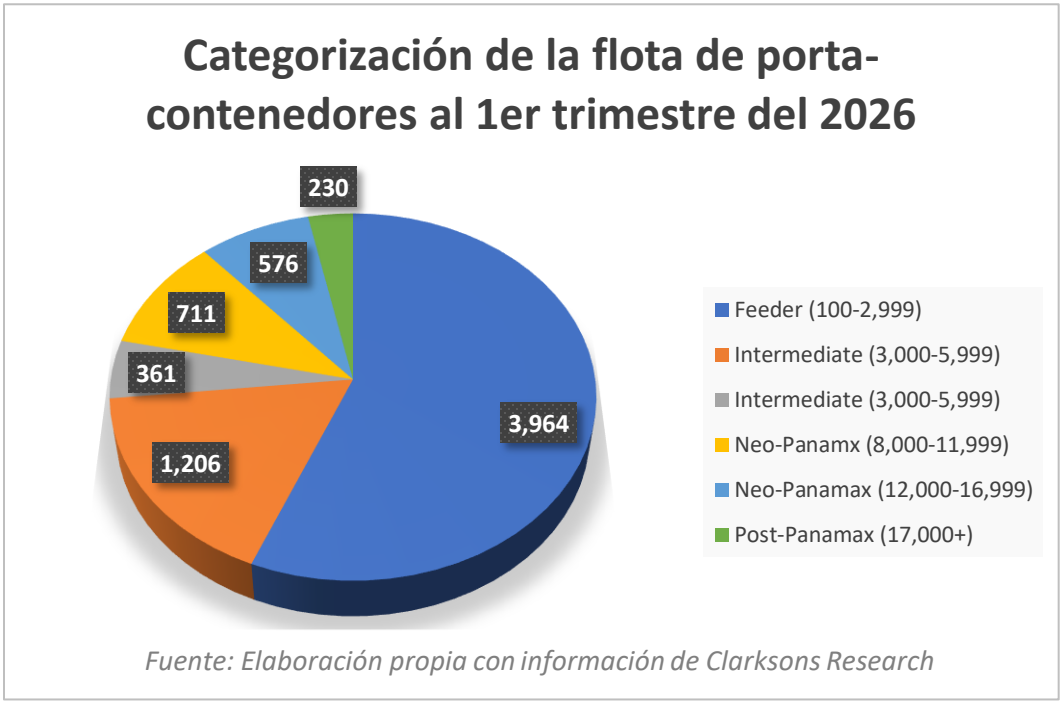

Figura 1-1. Categorización de la flota de porta-contenedores al 1er trimestre del 2026

En la figura anterior se observa que el segmento predominante corresponde a los buques tipo feeder (100–2,999 TEUs), con un total de 3,964 unidades, representando la mayor proporción de la flota mundial.

En segundo lugar, se encuentra el segmento intermedio (3,000–5,999 TEUs) con 1,206 buques, seguido por el rango de 6,000 a 7,999 TEUs con 361 unidades. Por su parte, los buques tipo Neo-Panamax presentan dos subcategorías: aquellos entre 8,000 y 11,999 TEUs con 711 unidades, y los de 12,000 a 16,999 TEUs con 576 unidades.

Finalmente, el segmento de mayor capacidad, correspondiente a buques Post-Panamax superiores a 17,000 TEUs, cuenta con 230 unidades, siendo el grupo con menor número de embarcaciones, pero que concentra una proporción significativa de la capacidad total de transporte.

En conjunto, la gráfica refleja una estructura de flota donde predominan los buques de menor tamaño en número, mientras que los buques de gran capacidad, aunque menos numerosos, desempeñan un papel clave en el transporte marítimo global.

Container Capable Fleet & Capacity — **March-26**

Containership Fleet	Numbers, start					million dwt, start					,000 teu capacity, start

1.2. Flota mundial de buques porta contenedores compatibles con el proyecto portuario de Cuyutlán

1.2.1. Análisis de la flota de buques porta-contendores de 20 mil TEUs (146 buques)

Para este apartado se utilizó la flota mundial existente de buques porta-contenedores de 20,000 TEUs o superiores, que consta de 146 embarcaciones con las siguientes características:

	GT	TPM	Calado de Verano (m)	Eslora (m)	Manga (m)	Número de TEUs nominal
Máximo	237,742	254,992	17	400	61.51	24,346
mínimo	194,852	190,326	14	399	58.50	20,000
Promedio	226,704	219,629	16	400	60.44	22,770

Tabla 1-2 Características máximas y mínimas de la flota de porta-contenedores de 20,000+ TEUs.

En la tabla anterior se muestran las principales características dimensionales y operativas de la flota de buques porta-contenedores con capacidades iguales o superiores a 20,000 TEUs, considerando valores máximos, mínimos y promedio. En términos de arqueo bruto (GT), los buques oscilan entre 194,852 y 237,742, con un valor promedio de 226,704.

Respecto al tonelaje de peso muerto (TPM o DWT por sus siglas en inglés), se identifican valores entre 190,326 y 254,992 toneladas, con un promedio de 219,629 toneladas. El calado de verano varía entre 14 y 17 metros, con un promedio de 16 metros, siendo este un parámetro crítico para la compatibilidad con la infraestructura portuaria.

En cuanto a las dimensiones principales, la eslora se mantiene prácticamente constante entre 399 y 400 metros, mientras que la manga varía entre 58.50 y 61.51 metros, con un promedio de 60.44 metros, lo cual corresponde a buques del tipo Ultra Large Container Vessel (ULCV).

Finalmente, el número de TEUs nominal se encuentra en un rango de 20,000 a 24,346 TEUs, con un promedio de 22,770 TEUs.

1.2.1.1. Buque máximo existente en la flota de porta-contenedores iguales o mayores a 20 mil TEUs

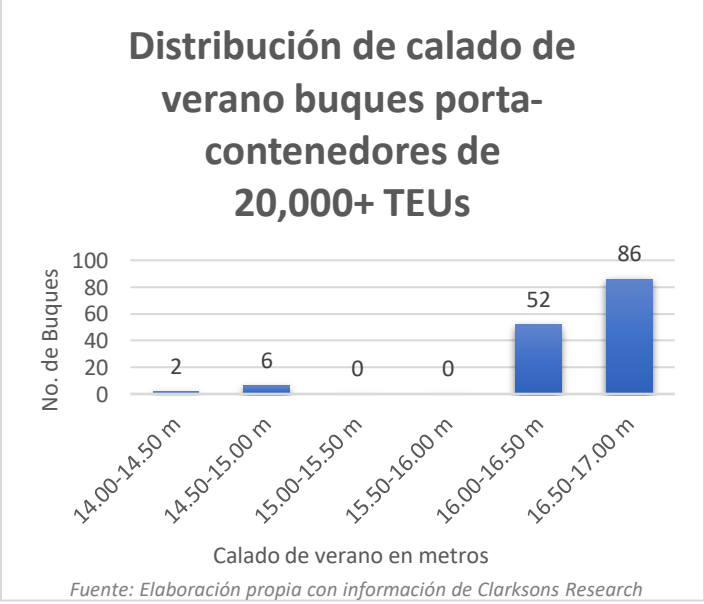
Derivado de los datos de la flota de buques porta-contendores mayores a 20 mil TEUs podemos concluir que el buque máximo de porta-contendores reportado en Clarksons al 9 de abril del 2025 es el siguiente:

Buque porta-contenedor máximo reportado en Clarksons Al 09-abril-2026 para flota +20k TEUs	
GT:	237,742
TPM	254,992
Calado de verano (m):	17
Eslora (m):	400
Manga (m):	61.51
TEUs nominales:	24,346

Fuente: Elaboración propia con información de Clarksons Research

Tabla 1-3. Buque máximo reportado en Clarksons al 09-abril-2026 para la flota de porta-contenedores mayores a 20,000 TEUs

1.2.1.2. Distribución de Calado (flota +20k TEUs)



Fuente: Elaboración propia con información de Clarksons Research

Figura 1-2. Distribución de calados de verano buques porta-contenedores de +20 mil TEUs

La gráfica muestra la distribución del número de buques por rangos de calado de verano, observándose que la mayoría de las embarcaciones se concentra en el

intervalo de 16.5 a 17.0 m, siendo 17 m el calado máximo registrado para este tipo de buques.

1.2.1.3. Distribución de Manga (flota +20k TEUs)

La gráfica presenta la distribución de la manga de los buques porta-contenedores con capacidades iguales o superiores a 20,000 TEUs, observándose una marcada concentración en el rango de 61.00 a 61.51 m.

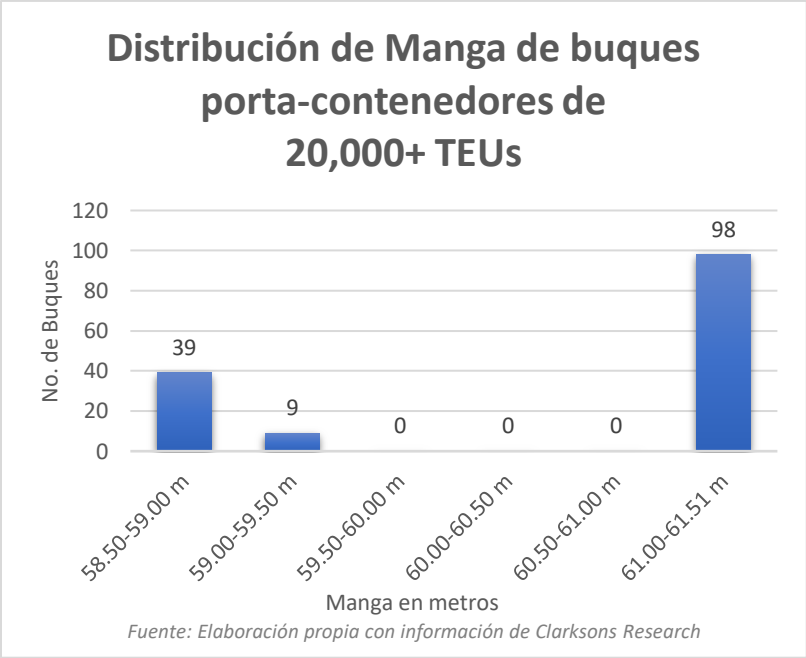


Figura 1-3. Distribución de Manga de buques porta-contenedores de +20 mil TEUs

1.2.1.4. Distribución de Eslora (flota +20k TEUs)

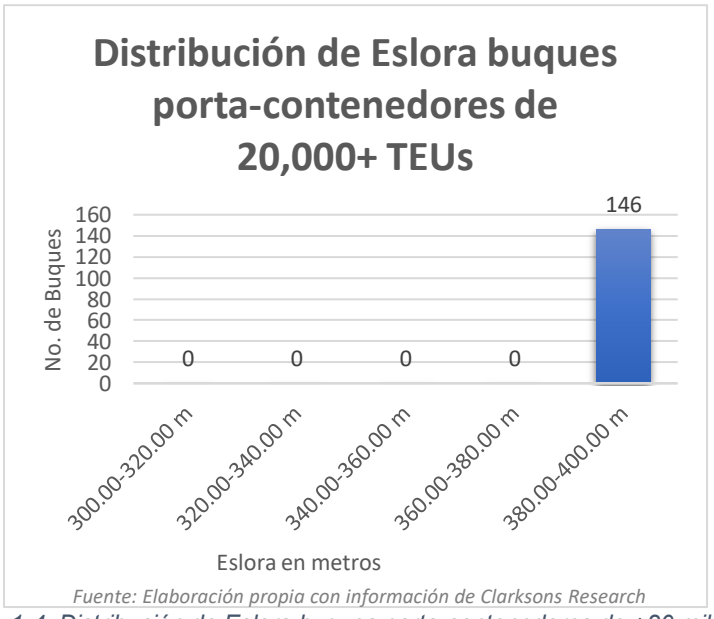

Figura 1-4. Distribución de Eslora buques porta-contenedores de +20 mil TEUs

La gráfica presenta la distribución de la eslora de los buques porta-contenedores iguales o superiores a 20,000 TEUs, observándose que la totalidad de las embarcaciones se concentra en el rango de 380 a 400 m. Más adelante, en las tablas, se muestra que estos buques presentan solamente esloras de 400 m.

1.2.1.5. Distribución de TEUs nominal (flota +20k TEUs)

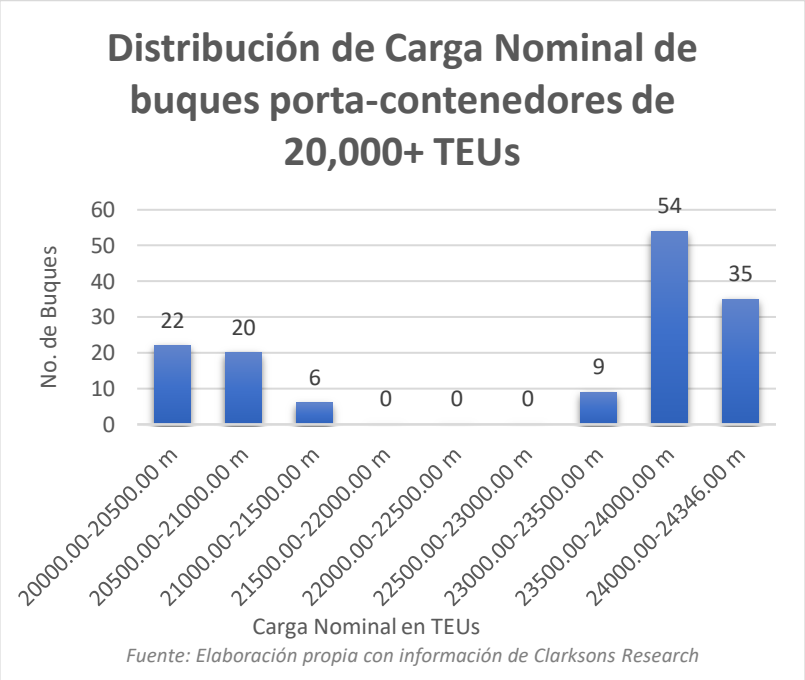

Figura 1-5. Distribución de Carga Nominal de buques porta-contenedores de +20 mil TEUs

La gráfica muestra la distribución de la carga nominal de los buques porta-contenedores con capacidades iguales o superiores a 20,000 TEUs, observándose que la mayoría de las embarcaciones se concentra en el rango de 23,000 a 24,346 TEUs.

1.2.2. Análisis de la flota de porta-contenedores iguales o mayores a 300 m de Eslora (1469 buques)

Asimismo, se estudió una muestra adicional de 1,469 buques registrados en *Clarksons Research* al 14 de abril de 2026, correspondiente a buques con esloras iguales o superiores a 300 m.

	GT	TPM	Calado de Verano (m)	Eslora (m)	Manga (m)	Número de TEUs nominal
Máximo	237,742	254,992	19	400	61.51	24,346
mínimo	72,760	77,220	12	300	40.00	6,402
Promedio	135,163	142,295	15	353	49.13	13,076

Tabla 1-4. Características máximas y mínimas de la flota de porta-contenedores de +300 m de Eslora.

La tabla anterior presenta las características principales de los buques porta-contenedores con esloras iguales o superiores a 300 m, incluyendo valores máximos, mínimos y promedio. En términos de arqueo bruto (GT), los valores oscilan entre 72,760 y 237,742, con un promedio de 135,163.

El peso muerto (TPM) varía entre 77,220 y 254,992 toneladas, con un valor promedio de 142,295 toneladas, mientras que el calado de verano se sitúa entre 12 y 19 m, con un promedio de 15 m.

En cuanto a las dimensiones principales, la eslora se eligió en un rango de 300 a 400 m, estos buques tienen un valor promedio de 353 m, y la manga varía entre 40.00 y 61.51 m, con un promedio de 49.13 m.

Finalmente, el número de TEUs nominal presenta un rango de 6,402 a 24,346 TEUs, con un promedio de 13,076 TEUs.

1.2.2.1. Buque máximo existente de la flota de buques porta-contenedores

Derivado de los datos de la flota de buques porta-contenedores con eslora (LOA - Length Overall, por sus siglas en inglés) igual o mayor a 300 m, podemos observar que las dimensiones del buque máximo son las siguientes:

Buque porta-contenedor máximo reportado en Clarksons al 14-abril-2026

GT:	237,742
TPM	254,992
Calado de verano (m):	**19**
Eslora (m):	400
Manga (m):	61.51
TEUs nominales:	24,346

Fuente: Elaboración propia con información de Clarksons Research

Tabla 1-5. Buque porta-contenedor máximo existente reportado en Clarksons al 14 de abril del 2026 para la flota de buques iguales o mayores a 300 m de eslora.

Esta tabla se mantiene con las mismas condiciones máximas que las presentadas en la muestra de buques de +20 mil TEUs, sin embargo, cambia el calado, a pesar de que los buques que se agregaron fueron menores a 20 mil TEUs. Mas adelante en la "Tabla de consulta rápida en base a TEUs Nominales" se puede observar que los buques con calado mayor a 17 m presentan TEUs nominales de entre 16 mil y 18 mil TEUs.

Haciendo un zoom de búsqueda específica se puede observar que son solamente **26** buques de los 1,469 estudiados y tienen capacidades de entre 16,000 y 17,480 TEUs.

1.2.2.2. Observación del buque máximo existente de la flota de buques con eslora igual o mayor a 300 m

Con los datos anteriores, se puede observar que un calado de **17 m**, abarcaría la flota objetivo, ya que, al aumentar la profundidad para soportar calados mayores, en el caso de porta-contenedores, solamente aumentaría la capacidad de carga de esos 26 buques que presentan capacidades nominales de 16 – 18 mil TEUs. Los buques de 20 mil a 24 mil TEUs, así como el resto de los buques analizados (flota de buques porta-contenedores iguales o mayores a 300 m de eslora) registran un calado de verano máximo de 17 m.

En una visualización de Clarksons, pudimos observar que los buques menores a 300 m de eslora, presentan un calado de verano máximo de 16 m.

1.2.2.3. Condiciones máximas de los buques de 300m de LOA

Mediante una consulta en la plataforma Clarksons Research, se obtuvieron los valores máximos de las principales características de los buques porta-contenedores con eslora igual o menor a 300 m, con el objetivo de contar con los parámetros necesarios para determinar, conforme a los criterios de PIANC, la longitud de muelle requerida para el atraque de este tipo de embarcaciones:

Condiciones máximas de los buques MENORES 300 LOA al 26-abril-2026	
GT:	102,931
TPM	125,000
Calado de verano (m):	16
Eslora (m):	300
Manga (m):	48.4
TEUs nominales:	10,926

Tabla 1-13. Tabla de consulta rápida en base a TEUs Nominal

Se puede observar que los buques de mayor capacidad nominal, presentan esloras de 400 m y calados de entre 14.5 m y 17 m.

1.2.3.4. Observación de las tablas de consulta rápida

En las tablas de consulta rápida se presentan los datos obtenidos del análisis de carga a calado restringido, los cuales fueron calculados considerando un peso promedio de 7.26 toneladas por TEU, valor tomado del Informe Estadísticas de Operación Portuaria enero–diciembre 2024–2025. Bajo este supuesto, una profundidad de -17 m resulta suficiente para permitir que los buques más grandes vayan a una carga mayor al 84%, sin embargo, para conseguir que todos los buques mayores a 22 mil TEUs vayan al 100% de carga, es necesario una profundidad de -18.5 m, más adelante se detallan los cálculos que nos llevaron a estos resultados.

1.2.4. Análisis de carga de buques porta-contenedores igual o mayores a 300 m de eslora

De acuerdo con el Informe Estadísticas de Operación Portuaria enero–diciembre 2024–2025 del puerto de Manzanillo en el 2025 se operaron 1,699,057 de importación llenos, y 1,340,005 de exportación llenos, no se tomaron en cuenta las cajas vacías, así mismo se operaron 22,051,002, dándonos un resultado de **7.26** toneladas por TEU.
Con base en este peso promedio por TEU, se realizaron diversas corridas para evaluar la capacidad de carga de los buques porta-contenedores analizados (iguales o mayores a 300 m de eslora).

1.2.4.1. Corrida 1 – Profundidad -14 m

Corrida 1 - Buques porta-contenedores
Capacidad de carga neta a calado restringido
Profundidad -14 m (7.26 t / TEU)

Figura 1-15. Corrida 6 - Distribución de buques porta-contenedores por carga en TEUs a profundidad -18.5 m

En esta gráfica se observa que la distribución de la carga se mantiene relativamente estable.

1.2.4.7. Conclusiones del análisis de carga

Al analizar los porcentajes de carga, se identifica que a una profundidad de -18.5 m se alcanza un mayor aprovechamiento de la capacidad de los buques. En particular, el 100% de los buques con capacidades mayores (entre 20,000 y 24,000 TEUs) logran operar al 100% de su capacidad, mientras que algunos buques en el rango de 16,000 a 18,000 TEUs alcanzan aproximadamente un 78% de carga.

Buques porta-contenedores igual o mayores a 300 m de Eslora		Corrida 1 Profundidad - 14 m		Corrida 2 Profundidad - 15 m		Corrida 3 Profundidad - 16 m		Corrida 4 Profundidad - 17 m		Corrida 5 Profundidad - 18 m		Corrida 6 Profundidad - 18.5 m

Tabla 1-20. Tabla de porcentajes de carga corridas 1-5

Por otro lado, para que la totalidad de la flota de buques porta-contenedores analizada pueda operar al 100% de su capacidad de carga, se requiere una profundidad de 20.5 m.

1.3. Análisis de las flotas de las líneas navieras de buques porta-contenedores que operan en diferentes puertos vs las flotas de las navieras que actualmente operan en Manzanillo.

Es importante identificar a las principales navieras a nivel mundial, ya que estas concentran la mayor capacidad de transporte de contenedores y dominan las rutas marítimas más relevantes. De acuerdo con el informe "Container Intelligence Monthly" de marzo de 2026, los operadores con mayor capacidad son los siguientes:

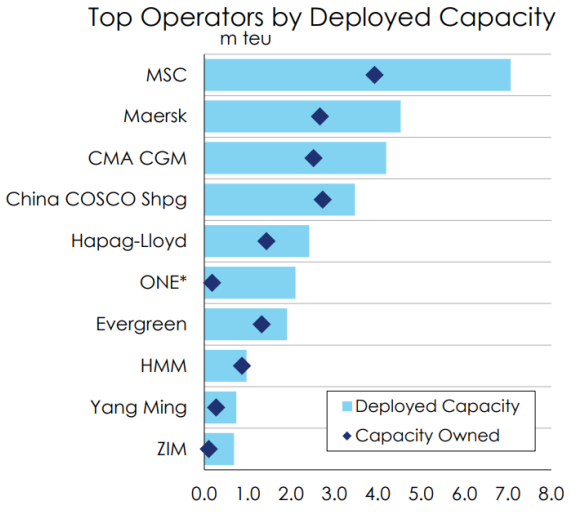

Figura 1-16. Operators by Deployed Capacity

Fuente: Container Intelligence Monthly Marzo 2026 página 22.

La gráfica muestra a los principales operadores de buques porta-contenedores a nivel mundial en función de su capacidad desplegada (barras) y su capacidad propia (marcadores), ambas expresadas en millones de TEUs. Se observa que MSC lidera ampliamente en capacidad desplegada, seguido por Maersk y CMA CGM, consolidándose como los tres principales actores del mercado.

Asimismo, se aprecia que en la mayoría de los casos la capacidad desplegada es superior a la capacidad propia, lo que indica una utilización significativa de buques fletados por parte de las navieras. Otros operadores relevantes incluyen China COSCO Shipping, Hapag-Lloyd, ONE y Evergreen, mientras que HMM, Yang Ming y ZIM presentan menores niveles de capacidad en comparación con los líderes del sector.

1.3.1. Análisis de presencia de navieras

Con el objetivo de complementar el análisis de la flota mundial de buques porta-contenedores y su compatibilidad con el proyecto portuario de Cuyutlán, en el presente apartado se evalúan las principales líneas navieras que operan en puertos estratégicos del corredor Asia–América. Se realizó un análisis de las principales navieras en los puertos estudiados (Busan, Shanghái, Long Beach, Los Ángeles, San Diego y Manzanillo-México), así como en otros puertos importantes en cuanto a tráfico de contenedores (Lázaro Cárdenas, Tokyo, Balboa-Panamá y Manzanillo-Panamá).

Este análisis permite identificar los operadores predominantes a nivel global, la capacidad de su flota y su presencia en diferentes nodos portuarios, con el fin de obtener un acercamiento a patrones de operación, rutas comerciales relevantes y la posible participación de dichas navieras en el desarrollo del proyecto

Se observa que la naviera con mayor presencia en número de puertos es MSC, con operación en 9 puertos, lo que refleja una amplia cobertura dentro del corredor Asia–América. Por otro lado, la naviera que concentra el mayor tonelaje de arqueo bruto (GT) es China COSCO Shipping, lo que indica una mayor operación en términos de volumen de transporte.

A continuación, se presentan las tablas clasificadas por colores, con el fin de facilitar la identificación de la presencia de cada naviera en los distintos puertos analizados. Las navieras mostradas en blanco y negro corresponden a aquellas que únicamente registran presencia en un solo puerto.

Tabla 1-23. Tabla de navieras con GT y presencia en puertos

En la tabla anterior, las navieras en color azul claro operan en puertos de Panamá.

1.3.2. Busan

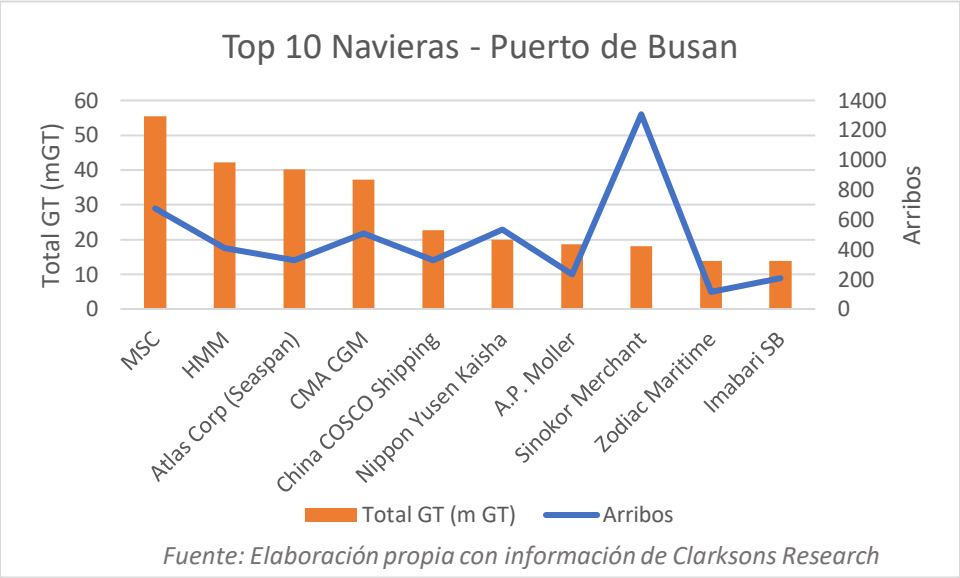

Figura 1-17. Top 10 Navieras - Puerto Busan (últimos 12 meses)

La gráfica muestra a MSC como la naviera con mayor presencia en el puerto de Busan, en términos de tonelaje total (GT). Asimismo, esta naviera mantiene operaciones en otros puertos relevantes a nivel internacional, como Manzanillo (México), Long Beach y Shanghái, lo que refleja su participación en las principales rutas del comercio marítimo de contenedores.

Se realizó una visualización en la plataforma Clarksons Research con el objetivo de identificar las características máximas de la flota de porta-contenedores de la naviera **MSC**:

Características Máximas de la flota de porta-contenedores de la naviera **MSC**	
GT	232,618
DWT	254,992
TEUs nominal	23,756
Eslora (m)	399.9
Manga (m)	61.51
Calado de verano (m)	19

Tabla 1-24. Tabla de las características máximas de la flota de porta-contenedores de la naviera MSC

Para ver más información sobre el puerto ver anexo "1.3.1. Port Busan, South Korea".

1.3.3. Shanghái

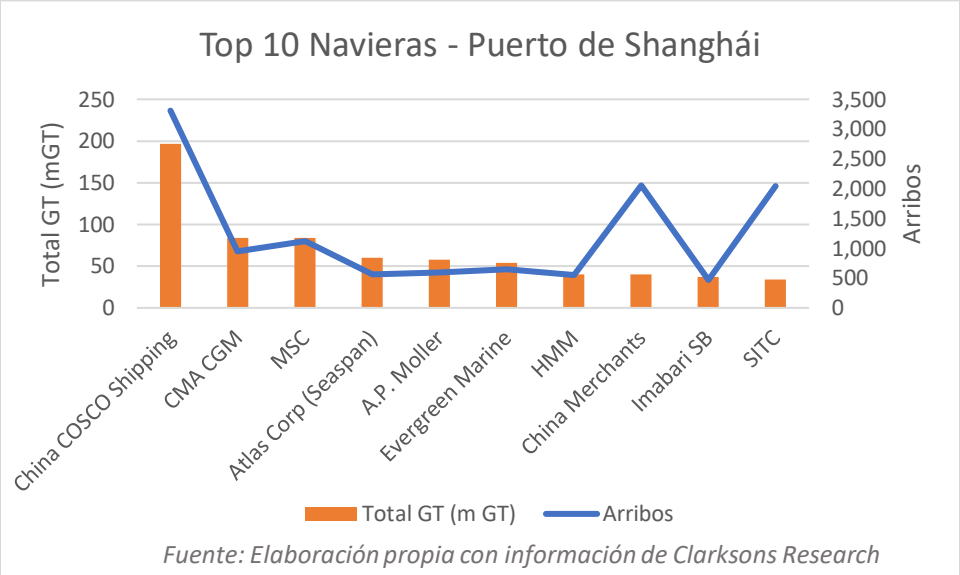

Figura 1-18. Top 10 Navieras - Puerto Shanghái (últimos 12 meses)

En el puerto de Shanghái, la naviera con mayor presencia en términos GT es China COSCO Shipping. Asimismo, esta naviera mantiene operaciones en otros puertos relevantes como Long Beach, Busan y Manzanillo, lo que refleja su presencia en puertos estratégicos del comercio transpacífico.
Se realizó una visualización en la plataforma Clarksons Research con el objetivo de identificar las características máximas de la flota de porta-contenedores de la naviera **China COSCO Shipping**:

Características Máximas de la flota de porta-contenedores de la naviera **China COSCO Shipping**	
GT	235,341
DWT	228,258
TEUs nominal	24,188
Eslora (m)	400
Manga (m)	61.3
Calado de verano (m)	16.5

Tabla 1-25. Tabla de las características máximas de la flota de porta-contenedores de la naviera China COSCO Shipping

Para más información sobre el puerto, ver anexo "1.3.2. Port Shanghai, China P.R".

1.3.4. Long Beach

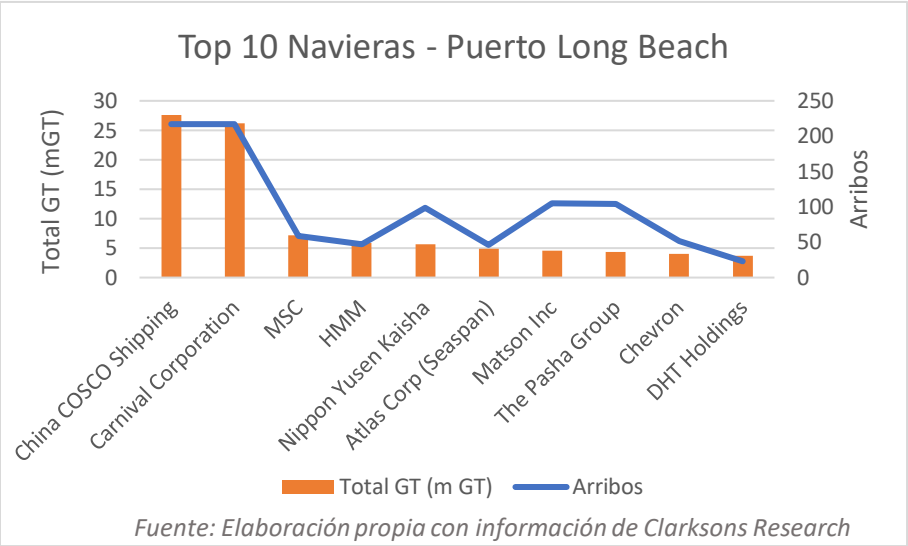

Figura 1-19. Top 10 Navieras - Puerto Long Beach (últimos 12 meses)

En el puerto de Long Beach, la naviera con mayor operación en términos de Gross Tonnage o Tonelaje de Arqueo Bruto (GT) es China COSCO Shipping.

La flota de China COSCO Shipping fue presentada en el puerto anterior, la naviera Carnival Corporation no tiene porta-contenedores, por tal motivo, se realizó una búsqueda en la plataforma Clarksons Research con el objetivo de identificar las características máximas de la flota de porta-contenedores de la naviera **HMM**:

Características Máximas de la flota de porta-contenedores de la naviera **HMM**	
GT	232,311
DWT	232,606
TEUs nominal	23,964
Eslora (m)	399.9
Manga (m)	61.5
Calado de verano (m)	16.53

Tabla 1-26. Tabla de las características máximas de la flota de porta-contenedores de la naviera HMM

Para más información sobre el puerto, ver anexo "1.3.3. Puerto Long Beach, United States".

1.3.5. Los Ángeles

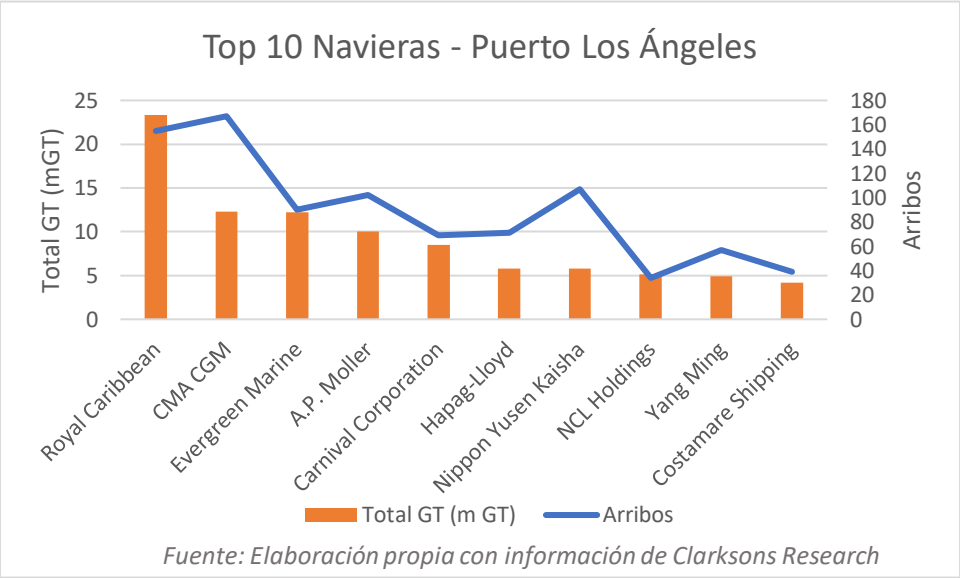

Figura 1-20. Top 10 Navieras - Puerto Los Ángeles (últimos 12 meses)

En el puerto de Los Ángeles, la naviera con mayor participación en términos de tonelaje de arqueo bruto (GT) es Royal Caribbean, sin embargo, esta naviera no posee porta-contenedores. La segunda naviera en importancia de GT, es CMA CGM. Para profundizar, se realizó una búsqueda en la plataforma Clarksons Research con el objetivo de identificar las características máximas de la flota de porta-contenedores de la naviera **CMA CGM**:

Características Máximas de la flota de porta-contenedores de la naviera **CMA CGM**	
GT	237,742
DWT	221,250
TEUs nominal	23,872
Eslora (m)	400
Manga (m)	61.3
Calado de verano (m)	16

Tabla 1-27. Tabla de las características máximas de la flota de porta-contenedores de la naviera CMA CGM

Para más información sobre el puerto, ver anexo "1.3.3. Puerto Long Beach, United States".

Para más información sobre el puerto, ver anexo "1.3.4. Port Los Angeles, United States".

1.3.6. San Diego

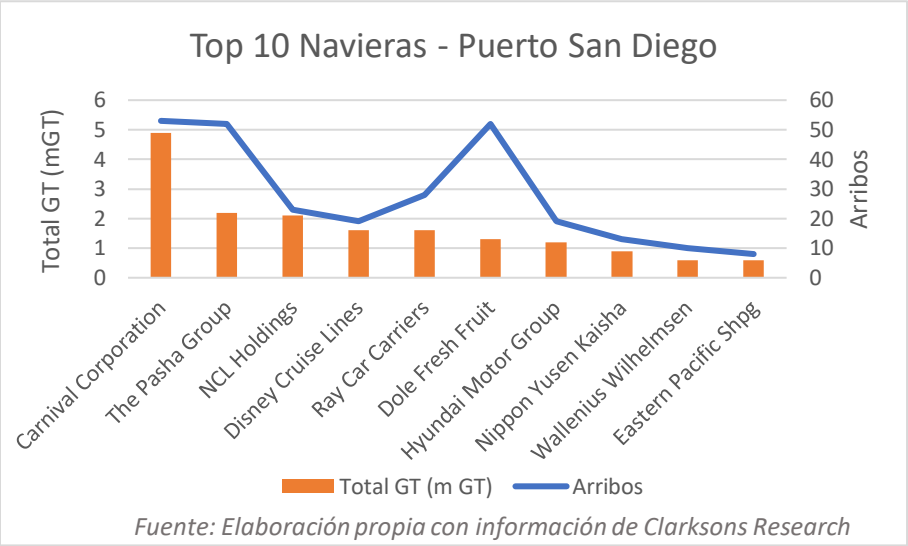

Figura 1-21. Top 10 Navieras - Puerto San Diego (últimos 12 meses)

En el puerto de San Diego, la naviera con mayor participación en términos de tonelaje de arqueo bruto (GT) durante los últimos 12 meses es Carnival Corporation, Como ya mencionamos, esta naviera no posee porta-contenedores. La segunda naviera en importancia de GT es The Pasha Group. Se realizó una búsqueda en la plataforma Clarksons Research con el objetivo de identificar las características máximas de la flota de porta-contenedores de la naviera **The Pasha Group**:

Características Máximas de la flota de porta-contenedores de la naviera **The Pasha Group**	
GT	42,600
DWT	46,154
TEUs nominal	2,653
Eslora (m)	272.3
Manga (m)	36
Calado de verano (m)	12.44

Tabla 1-28. Tabla de las características máximas de la flota de porta-contenedores de la naviera The Pasha Group

Esta naviera posee la flota más pequeña de las analizadas hasta el momento.

Para más información sobre el puerto, ver anexo "1.3.5. Port San Diego, United States".

1.3.7. Manzanillo

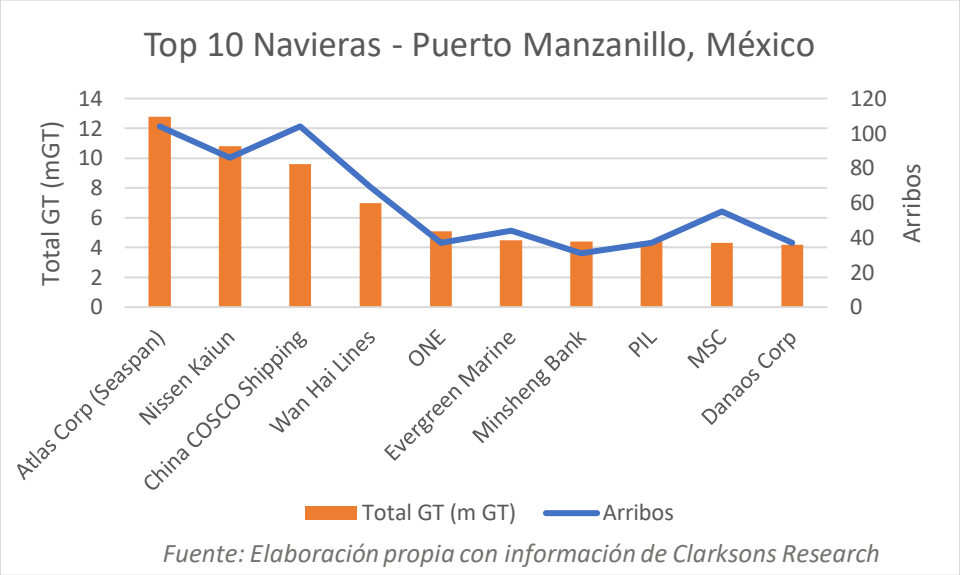

Figura 1-22. Top 10 Navieras - Puerto Manzanillo, México (últimos 12 meses)

De acuerdo con los reportes de Clarksons Research, la naviera con mayor operación en términos de tonelaje de arqueo bruto (GT) en el puerto de Manzanillo es Atlas Corp (Seaspan), cuya flota de buques porta-contenedores presenta las siguientes características máximas:

Características Máximas de la flota de porta-contenedores de la naviera **Atlas Corp (Seaspan)**	
GT	233,328
DWT	240,931
TEUs nominal	24,346
Eslora (m)	399.9
Manga (m)	61.3
Calado de verano (m)	17

Tabla 1-29. Tabla de las características máximas de la flota de porta-contenedores de la naviera The Pasha Group

Para más información reportada en Clarksons sobre el puerto, ver anexo "1.3.6. Port Manzanillo, México".

1.3.8. Top 10 Navieras por mGT, arribos, presencia en puertos y relevancia operativa

Las navieras fueron organizadas en función de su presencia en términos de tonelaje de arqueo bruto (mGT), número de arribos y número de puertos del Pacífico en los que operan, obteniéndose los siguientes resultados:

Las 10 navieras con más presencia en mGT son:

1. China COSCO Shipping
2. MSC
3. CMA CGM
4. Atlas Corp (Seaspan)
5. Nissen Kaiun
6. A.P. Moller
7. Evergreen Marine
8. HMM
9. Imabari SB
10. Nipon Yusen Kaisha

Las 10 navieras con mayor cantidad de arribos son:

1. China COSCO Shipping
2. MSC
3. SITC
4. China Merchants
5. CMA CGM
6. Sinokor Merchant
7. A.P. Moller
8. Atlas Corp (Seaspan)
9. Nippon Yusen Kaisha
10. Evergreen Marine

Las 10 navieras que operan en más puertos son:

1. MSC
2. Atlas Corp (Seaspan)
3. Nippon Yusen Kaisha
4. Evergreen Marine
5. CMA CGM
6. China COSCO Shipping
7. A.P. Moller
8. Imabari SB
9. Zodiac Maritime
10. HMM

Con el objetivo de identificar a las navieras con mayor relevancia operativa en los puertos analizados, se desarrolló un modelo de evaluación basado en tres criterios:

tonelaje de arqueo bruto (mGT), número de puertos donde operan y número de arribos.

Para cada criterio, se asignó un puntaje relativo del 1 al 10, donde 10 corresponde al mayor valor observado dentro del conjunto analizado y 1 al menor valor dentro del Top 10 de cada categoría.

Posteriormente, estos puntajes fueron ponderados en función de su importancia relativa dentro del análisis, otorgando mayor peso al mGT, seguido por la presencia en puertos y, finalmente, el número de arribos. A partir de esta ponderación, se obtuvo un puntaje global para cada naviera, permitiendo establecer un ranking de relevancia operativa en el corredor del Pacífico.

Top 10 navieras con mayor relevancia operativa:

1. MSC
2. China COSCO Shipping
3. Atlas Corp (Seaspan)
4. CMA CGM
5. A.P. Moller
6. Evergreen Marine
7. Nippon Yusen Kaisha
8. Nissen Kaiun
9. Imabari SB
10. HMM

1.3.9. Observación del análisis de las flotas de las líneas navieras

Actualmente, el puerto de Manzanillo opera con las tres navieras de mayor relevancia operativa en el Pacífico, identificadas como MSC, China COSCO Shipping y Atlas Corp (Seaspan).

1.4. Buque máximo teórico

Con el objetivo de definir un escenario límite para el diseño y evaluación de la infraestructura portuaria, se considera como buque máximo teórico aquel buque porta-contenedores que presenta las mayores dimensiones registradas en la base de datos de Clarksons Research. Este enfoque permite establecer condiciones conservadoras de diseño, tomando como referencia las características más exigentes en términos de eslora, manga, calado y capacidad de carga, a fin de evaluar la compatibilidad operativa del proyecto frente a la flota mundial actual.

Cabe señalar que este buque de dimensiones máximas fue presentado previamente en el tema "1.2. Flota mundial de buques porta-contenedores compatibles con el proyecto portuario de Cuyutlán"; no obstante, a continuación, se presentan nuevamente sus principales características.

Buque porta-contenedor máximo teórico reportado en Clarksons al 14-abril-2026	
GT:	237,742
TPM	254,992
Calado de verano (m):	19
Eslora (m):	400
Manga (m):	61.51
TEUs nominales:	24,346

Fuente: Elaboración propia con información de Clarksons Research

Tabla 1-30. Buque porta-contenedor máximo teórico reportado en Clarksons al 14 de abril del 2026 para la flota de buques iguales o mayores a 300 m de eslora.

1.5. Parámetros de seguridad operativos que se deben de respetar de acuerdo con las recomendaciones del PIANC

1.5.1. Determinación de UKC

De acuerdo con PIANC, el UKCNet está destinado principalmente a la etapa determinística de diseño conceptual (Concept Design, CD). ICORELS (1980) definió el UKCNet como el margen mínimo remanente entre la quilla del buque y el nivel nominal del fondo del canal, considerando que el buque se desplaza a la velocidad de diseño bajo la influencia de las condiciones más severas de viento y oleaje previstas para los límites operativos.
g

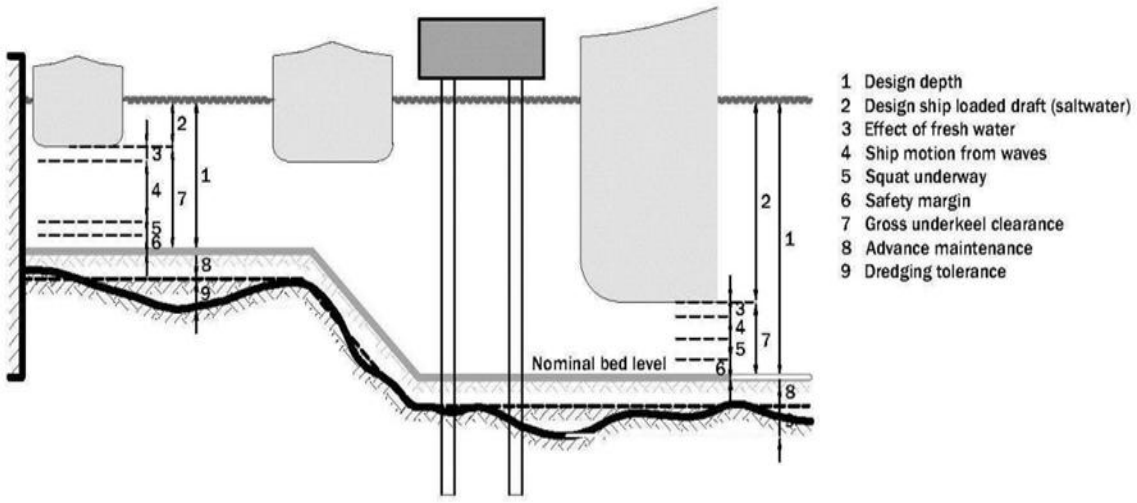

Figura 1-23. Parámetros típicos de profundidad

1. Profundidad del canal
2. Calado de diseño con el buque cargado (en agua salada)
3. Efecto de agua dulce
4. Movimientos del buque debido al oleaje
5. Efecto "Squat" durante la aproximación
6. Margen de seguridad
7. Espacio grueso libre bajo la quilla (UKC)

Por lo tanto, el UKCNet requerido corresponde al margen de "seguridad" que queda disponible para el buque después de descontar otros factores asociados a la embarcación (movimientos verticales inducidos por el oleaje, squat del buque y escora dinámica) de la profundidad o nivel nominal del fondo del canal.

Para la determinación del UKC mínimo requerido, se consideró la suma de los principales factores que incrementan el calado efectivo del buque durante la maniobra de aproximación, incluyendo el efecto de agua dulce, los movimientos del buque inducidos por el oleaje, el efecto squat y un margen de seguridad dándonos como resultado un **UKC de 1.28 m.**

Cálculo para Under Keel Clearance (UKC)

Parámetro	Valor	Unidad	Comentario
Profundidad del Canal	20.5	m	
Calado	19	m	Calado de diseño del buque en agua salada
Efecto de agua dulce	0.197916	m	
Movimientos del buque debido al oleaje	0.3048	m	
Coeficiente de block	0.75		
Velocidad de aproximación	5		
Efecto Squat durante la aproximación	0.375	m	
Margen de seguridad	0.4	m	
UKC	*1.277717*	*m*	

1.5.1.1. Efecto squat (incremento de calado por asiento)

Para calcular el espacio libre bajo la quilla es necesario sumarle al calado del barco el incremento de calado por efectos del fenómeno conocido como squat mediante la siguiente fórmula:

$S\ (\text{metros}) = (Cb \times V^2 / 100) \times 2$

Siendo:
S = sinkage (incremento de calado)
Cb = Coeficiente de block 0.75
V = Velocidad del buque en nudos (5 nudos en este caso, ya que es la mínima velocidad en la que es funcional el timón)
Por lo tanto, la fórmula en este caso queda de la siguiente manera:
$S = (0.75 \times 5^2 / 100) \times 2 = 0.375$ m

El coeficiente de block se tomó de acuerdo con el "*Annex C.1 Typical Ship Dimensions from ROM 3.1*" del "Report n° 121 – 2014. Harbour Approach Channels Design Guidelines". Para los contenedores, el coeficiente de block máximo es de 0.71, sin embargo, se tomó 0.75 como un promedio general mundial.

Tabla 1-31. Typical Ship Dimensions from ROM 3.1

1.5.2. Determinación de longitud de muelle, ángulos de atraque PIANC

De acuerdo con PIANC, en los muelles tipo "marginal" (quay wall), los ángulos que deben de guardar los cabos "largos" (head lines) deben conservar un ángulo de 45° ± 15° con respecto al muelle.
Los cabos de través deben conservar un ángulo de 90° (perpendicular al muelle) ± 30°.
Los ángulos para los cabos springs deben conservar un ángulo de entre 5° y 10°.

2. Condiciones de tráfico

2.1. Análisis comparativo entre los puertos de Busan, Shanghái, Long Beach, Los Ángeles y el puerto proyectado de Cuyutlán, respecto a sus capacidades máximas, tiempos en tránsito desde boya de recalada al muelle/muelles

Mediante una visualización en la plataforma MarineTraffic, se identificaron los países de origen y destino de los buques porta-contenedores que arribaron a los puertos de Busan, Shanghái, Long Beach y Los Ángeles durante el periodo comprendido entre el 30 de abril de 2025 y el 28 de abril de 2026. Asimismo, se determinó el buque porta-contenedor de mayores dimensiones que ingresó a cada uno de estos puertos durante dicho periodo.

180,000	165,350	366	51.2	15.6	15,000

Tabla 2-12. Características máximas de porta-contenedores que han entrado al puerto de Los Ángeles

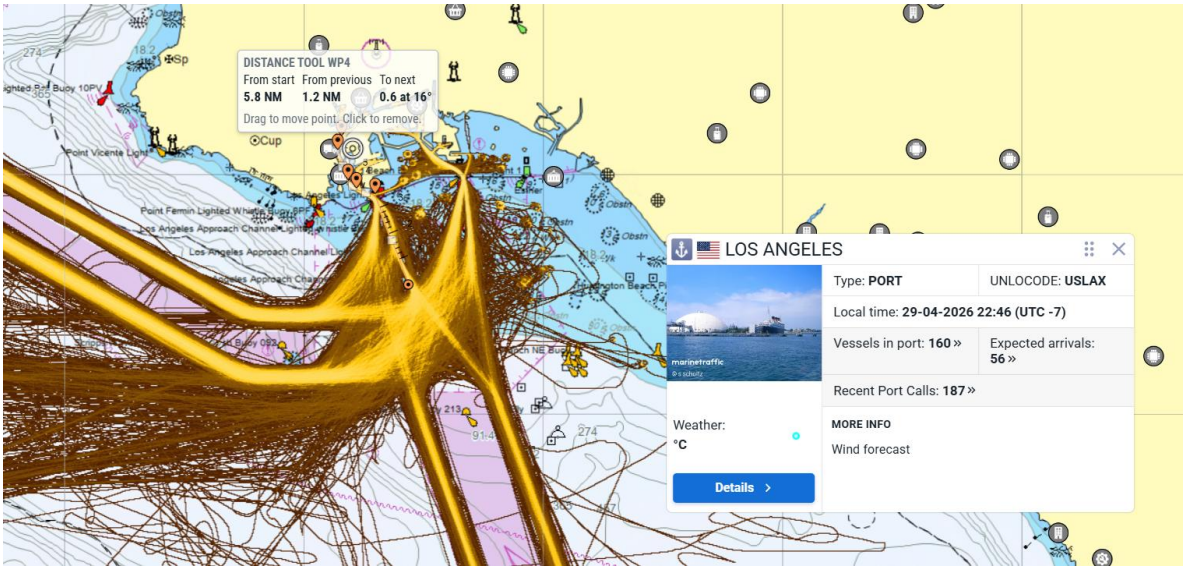

Figura 2-11. Distancia promedio de la booya de recalada a los muelles. Puerto Los Angeles. Marine Traffic. 5.8 MN

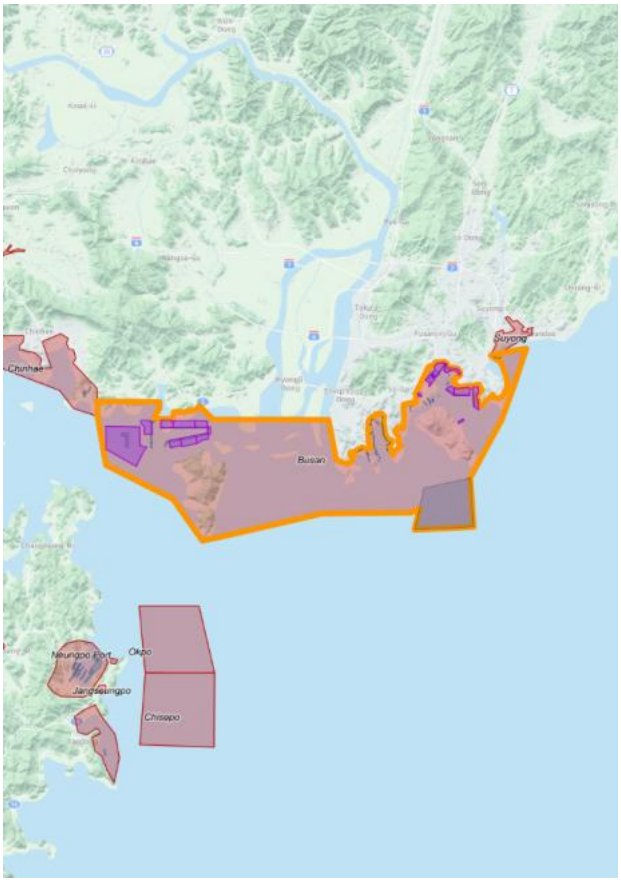

Figura 2-12. Portulano de navegación. Puerto Los Angeles

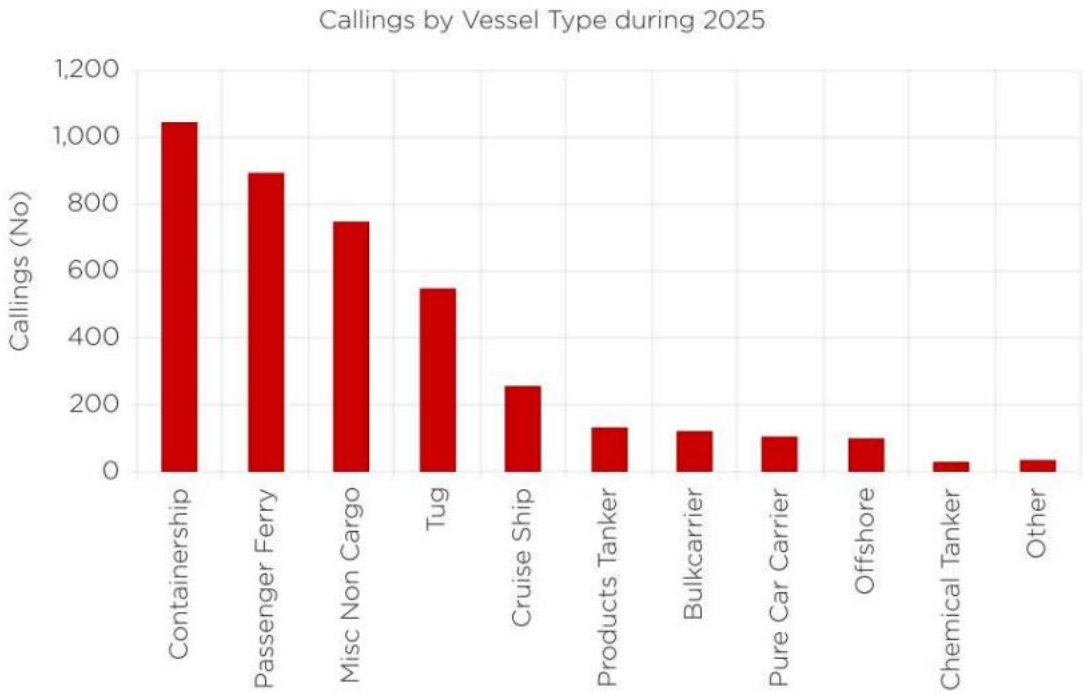

Figura 2-13. Arribos por tipo de buques durante el 2025. Puerto Los Angeles, US.

1,041 arribos de buques porta-contenedores durante el 2025, de acuerdo con Clarksons.

2.1.5. Puerto proyectado de Cuyutlán

La distancia desde la boya de recalada al muelle de porta-contenedores de Cuyutlán es de 4.1 MN.

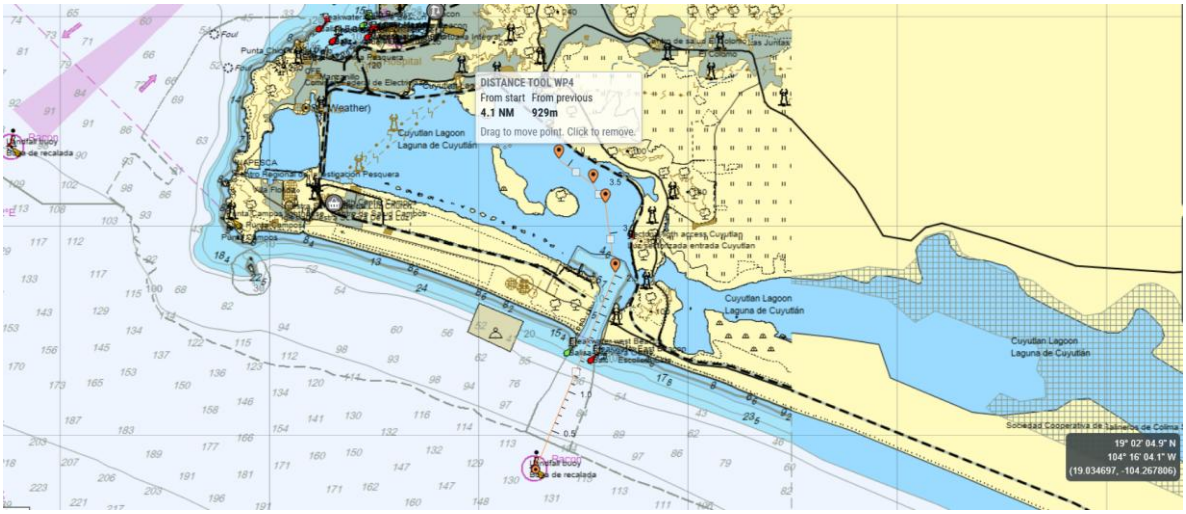

Figura 2-14. Distancia desde la boya de recalada al muelle de Cuyutlán

De acuerdo a la "INFORMACIÓN GENERAL DEL PROYECTO, PLAN O PROGRAMA" del CAPÍTULO II "MANIFESTACIÓN DE IMPACTO AMBIENTAL MODALIDAD REGIONAL DESARROLLO DEL PUERTO NUEVO MANZANILLO, EN EL VASO II DE LA LAGUNA CUYUTLÁN, COL", en la "Figura II. 1. Localización general del puerto nuevo de Manzanillo, en el vaso II de la laguna Cuyutlán, Colima" las terminales se van a construir en 2 etapas, la 1ª etapa 2 muelles y en la 2ª etapa 3 muelles.

La eslora promedio que se prevee que va a entrar a Cuyutlán en la 1ª etapa de 2 muelles es una eslora máxima promedio de 333 m, con un calado promedio de 14.4 m y manga promedio de 44.1 m.

En cuanto al tráfico, se estima que va a haber 101 entradas y 101 salidas mensuales, equivalentes a maniobras diarias de 3 entradas y 3 salidas y toda vez que la distancia de la boya de recalada promedio a los muelles es de 4.1 MN y la velocidad va a ser de 5 nudos promedio, entonces el tránsito en el canal de navegación va a ser de 1 hora promedio dando una ocupación del canal de navegación de 6 horas, tiempo suficiente para una maniobra segura.

Para la 2ª etapa va a haber 5 muelles en el Vaso II.

A pesar de que ha bajado el número de arribos, vamos a tomar de referencia el crecimiento del año 2022 al 2023 para calcular el nivel de crecimiento en esta 2ª etapa.
De acuerdo con lo anterior, se proyectan en la 1ª Etapa 1,228 arribos anuales, 102 arribos mensuales, 3 arribos diarios.
En la 2ª Etapa, se proyectan 1,295 arribos anuales, 107 arribos mensuales y 3 arribos diarios.

2.2. Condiciones de tráfico actual del puerto de Manzanillo

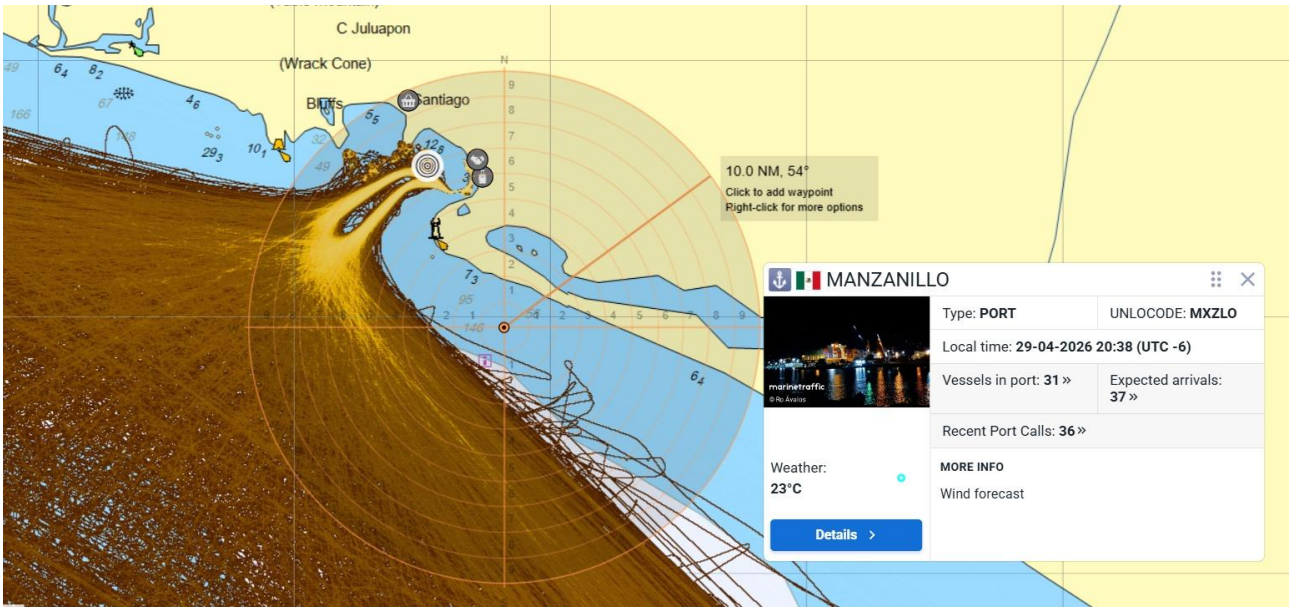

Figura 2-15. Densidad del tráfico de buques porta-contenedores en el actual puerto de Manzanillo

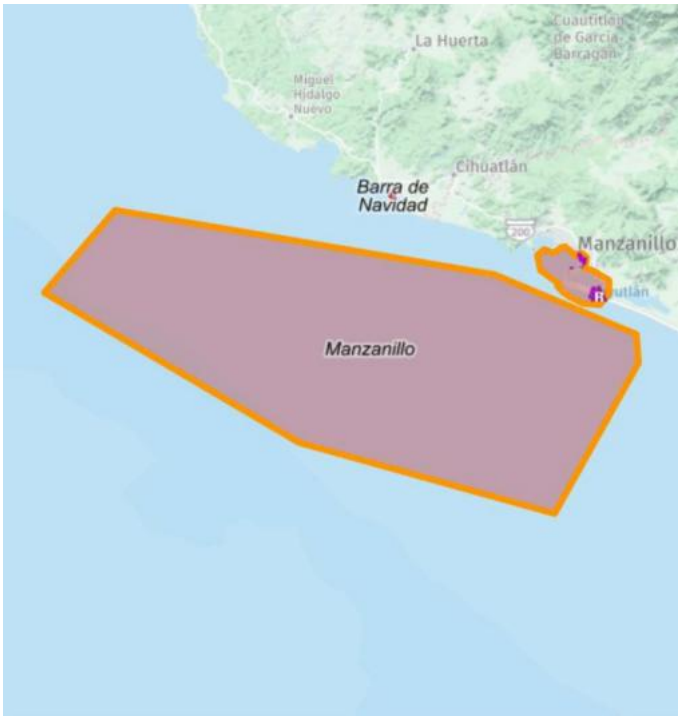

Figura 2-16. Portulano de Navegación. Puerto actual de Manzanillo

Manzanillo recibió 1,165 arribos de buques porta-contenedores en el 2025 (fuente: Clarksons).

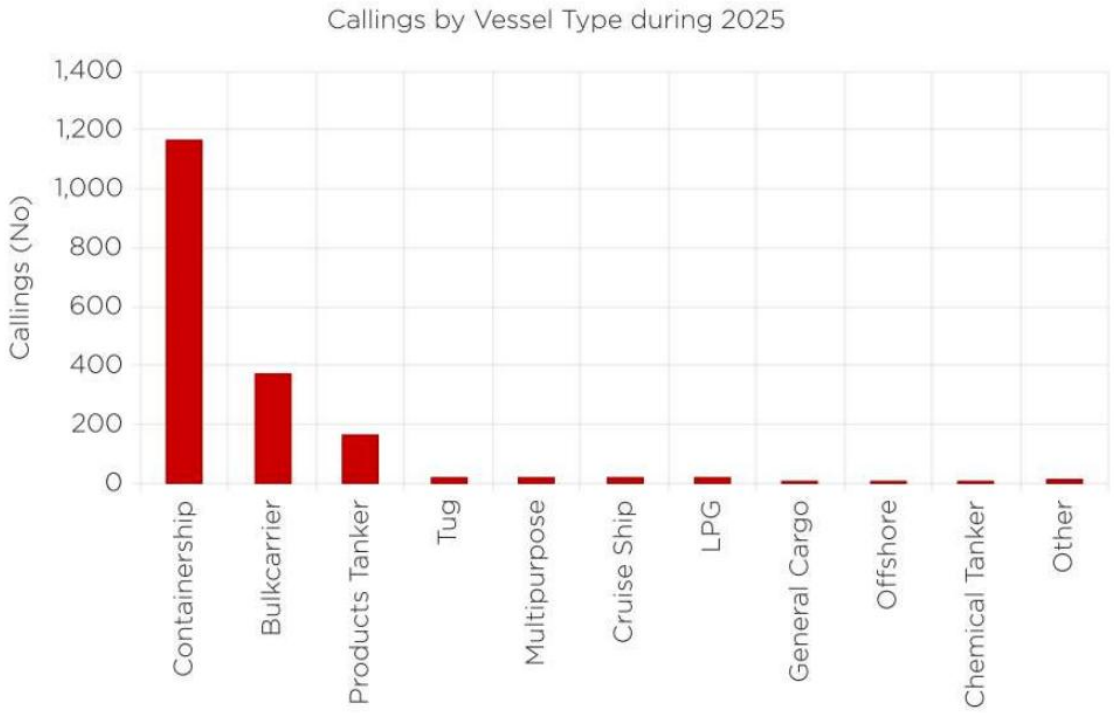

Figura 2-17. Arribos por tipos de buques durante el 2025. Puerto Manzanillo, México

Buque máximo recibido en el actual puerto de Manzanillo, México						
	Capacity - Dwt	**Capacity - Gt**	**Capacity - Teu**	**Draught - m**	**Length Overall - m**	**Breadth Extreme - m**

Promedio	105,917	94,280	9,092	12	302	42
mínimo	12,306	9,743	880	6	141	23

Figura 2-18. Buque máximo recibido en el actual puerto de Manzanillo, México

2.3. Condiciones de tráfico a futuro de Cuyutlán

De acuerdo con la página del puerto de Manzanillo (https://www.puertomanzanillo.com.mx/esps/0020303/terminales-e-instalaciones.html#:~:text=Manzanillo%20cuenta%20con%20muchas%20terminales%20para%20el,manejo%20de%20clinker**%20Capacidad%20de%2050.000%20toneladas) la Terminal Especializada en el manejo de contenedores (TEC), con capacidad de operación de hasta tres buques simultáneamente, y rendimientos de hasta 120 cajas por hora buque. Esto nos da una estadía promedio aproximada por barco de 1 día por muelle.

En base a lo anterior, en la 1ª etapa se incrementará la capacidad diaria de recepción de buques de 3 a 7, y en la 2ª etapa de 7 a 10 buques diarios.

2.4. Rutas de tránsito por tipo de buque (AIS histórico – MarineTraffic)

En este apartado se presentan las principales rutas de tránsito asociadas al Puerto de Manzanillo, identificadas a partir de los puertos de origen y destino de las embarcaciones. Dichas rutas se analizan y clasifican en función del tipo de buque.

3. Opinión de expertos y relación con el VTS "*Vessel Traffic System*" de Manzanillo para cuestiones de impacto ambiental

3.1. Opinión técnica de expertos en pilotaje

3.1.1. Opinión del Cap. de Altura José Luis Hernández Abdalah para la proyección completa del nuevo puerto considerando 7 muelles

Con el crecimiento que se le está proyectando a Manzanillo como un Puerto HUB, el tráfico de embarcaciones va a subir exponencialmente en un 300%, por lo tanto, las reglas de operación del VTS deben ser abordadas considerando las cuestiones de:

1. Seguridad de la Vida Humana en la Mar
2. Protección del medio ambiente marino

Para esto, es importante destacar que se tienen que seguir las reglas de la IALA para tal efecto y por lo tanto se creen división de flujos de tráfico de acuerdo a las recomendaciones de la OMI. En este sentido, es necesario destacar que la capacitación a los operadores de control de tráfico marítimo se debe impartir por personal certificado de la IALA para tal efecto.

Actualmente la única entidad mexicana en este sentido, es el (FUMPM) FIDEICOMISO de Escuelas Náuticas, que en la actualidad no se da abasto para cumplir con estas funciones, y por lo tanto se deben considerar la posibilidad de que se certifiquen a otras entidades privadas para tal efecto.

Además, el Sistema de Control de Tráfico Marítimo debe participar de una manera muy concreta en la protección de la fauna marina principalmente hacia las ballenas y ballenatos donde se controle la propulsión y el sonido acústico de acuerdo a las directrices que está indicando la OMI en su guía "DIRECTRICES REVISADAS PARA REDUCIR EL RUIDO SUBMARINO RADIADO DEBIDO AL TRANSPORTE MARÍTIMO CON EL FIN DE ABORDAR"
SUS EFECTOS ADVERSOS EN LA FAUNA MARINA y que establece varios rubros entre los que podemos mencionar la "optimización del asiento y el calado del buque puede reducir la potencia necesaria" y" el ajuste y optimización de la ruta del buque, la velocidad y el tiempo de navegación para reducir el tiempo que esté fondeado y el ruido submarino radiado en puerto y zonas costeras", entre otras.
Es importante determinar un radio de 10 MN para que a partir de que las embarcaciones ingresen a ese radio, empiecen a navegar de acuerdo a las instrucciones que les esté dando el radarista de guardia en el Sistema de Control de Tráfico Marítimo.
Por lo tanto, la torre de control deberá de asegurarse que las embarcaciones cumplan con las reglas de operación para tal efecto.

3.1.2. Avistamientos de ballenas en inmediaciones del puerto de Manzanillo, Col.

I.- La temporada en que se tiene conocimiento de avistamientos es en invierno (diciembre a marzo)
Lugares en los que normalmente son avistadas: en la costa entre La Piedra Blanca y Melaque, y esporádicamente en las bahías de Manzanillo y Santiago.
Debido a que son animales tímidos, que se asustan fácilmente con el ruido de los grandes barcos, por lo que se recomienda salir a pasear en una embarcación con motor fuera de borda con un caballaje entre 100 y 170 HP.

A.- La Autoridad encargada de proporcionar los permisos a las embarcaciones marítimas son:
Secretaria del medio ambiente (SEMARNAT, Oficina vida silvestre), y quien vigila su cumplimiento es PROFEPA, para avistamientos en específico y en general, a los prestadores de servicios turísticos de Manzanillo, no les conviene conseguir este tipo de permisos, ya que sus servicios están diversificados a: pesca deportiva, buceo y no para avistamiento de ballenas, reconociéndose a la Secretaria de Turismo, como la autoridad que otorga citados permisos.

B.- Los prestadores de servicios se encuentran principalmente en: muelle de pescadores de Manzanillo Centro, muelle turistico de las Hadas y en la playa de la Boquita.

Rosco Man en Manzanillo
314-123-0987

Compañía Double Trouble charters en Las Hadas
314-106-1874
314-198-9819

Hugo Rodriguez pesca deportiva y paseos en Las Hadas
314-106-4170

Extreme Ray pesca tour en la Boquita.
314-352-0780

II.- Conclusiones y recomendaciones

Se recomienda la Compañía Double Trouble en Las Hadas

3.2. Responsabilidades y alcances del Centro de Control de Tráfico Marítimo.

Marco institucional: IALA

La International Association of Marine Aids to Navigation and Lighthouse Authorities es el organismo internacional encargado de establecer estándares, recomendaciones y mejores prácticas para las ayudas a la navegación marítima y los Servicios de Tráfico Marítimo (VTS).

Su marco normativo se enfoca en:

3. Seguridad de la vida humana en el mar
4. Eficiencia del tráfico marítimo
5. Gestión de riesgos operacionales
6. Protección del medio ambiente marino

Estos lineamientos se desarrollan en concordancia con instrumentos internacionales como el International Maritime Organization, particularmente el Convenio SOLAS.

Centro de Control de Tráfico Marítimo (VTS) en Manzanillo

El puerto de Manzanillo es uno de los principales puertos del Pacífico mexicano, lo que requiere una gestión eficiente del tráfico marítimo mediante sistemas VTS.

Responsabilidades operativas

El VTS desarrolla funciones basadas en vigilancia, información y organización del tráfico:

- Supervisión del tráfico marítimo mediante radar, AIS y comunicaciones VHF
- Provisión de información sobre condiciones meteorológicas y riesgos
- Coordinación de maniobras de entrada, salida y tránsito
- Prevención de colisiones, encallamientos y congestión
- Apoyo en emergencias marítimas

Fuente:
IALA. VTS Manual (IALA V-127) https://www.iala.int/product/vts-manual/

Alcances y facultades

Conforme a estándares internacionales:

- El VTS no sustituye la autoridad del capitán
- Proporciona servicios de información, asesoramiento e instrucciones según normativa
- Puede organizar el tráfico mediante sistemas de separación y control de accesos

Estas disposiciones se encuentran respaldadas por el Convenio SOLAS.

Fuente:
International Maritime Organization. SOLAS Convention, Chapter V – Safety of Navigation
https://www.imo.org/en/About/Conventions/Pages/SOLAS.aspx

Protección de rutas de ballenas y gestión ambiental

El área del Pacífico mexicano donde se ubica Manzanillo forma parte de rutas migratorias de cetáceos, lo que introduce un componente ambiental relevante en la gestión portuaria.

El VTS contribuye a la mitigación de impactos mediante:

- Monitoreo de zonas con presencia de fauna marina
- Emisión de avisos a embarcaciones
- Recomendación de reducción de velocidad
- Propuesta de rutas alternativas
- Coordinación con autoridades ambientales

Estas acciones responden al enfoque de protección ambiental promovido por IALA y organismos internacionales.

International Maritime Organization. Guidance on ship strikes with cetaceans

https://www.imo.org/

3.3. Comparación con otros puertos ubicados en el océano Pacífico (Puerto de Prince Rupert y Puerto de Vancouver)

En el contexto actual del comercio internacional, los puertos marítimos se han convertido en elementos clave para el desarrollo económico de los países. Su crecimiento ha permitido facilitar el intercambio de mercancías a gran escala; sin embargo, también ha generado impactos significativos en los ecosistemas marinos. Uno de los más importantes es la afectación a las rutas migratorias de las ballenas, particularmente en el océano Pacífico.

Las ballenas realizan migraciones de larga distancia que abarcan miles de kilómetros. Estas rutas conectan zonas de alimentación ubicadas en aguas frías con áreas de reproducción en regiones más cálidas. Durante este proceso, los cetáceos dependen de condiciones ambientales específicas, como la disponibilidad de alimento, la temperatura del agua y la ausencia de perturbaciones externas.

Sin embargo, el crecimiento del tráfico marítimo ha provocado una superposición directa entre estas rutas naturales y las rutas de navegación comercial. Esto ha generado una interacción constante que pone en riesgo la integridad de las poblaciones de ballenas.

Importancia biológica de las rutas migratorias

Las rutas migratorias no solo representan trayectorias de desplazamiento, sino que constituyen sistemas complejos que permiten la supervivencia de las especies. A través de estas rutas, las ballenas acceden a recursos esenciales y mantienen el equilibrio de los ecosistemas marinos.

En el Pacífico norte, regiones como la Columbia Británica destacan por su alta biodiversidad y por ser puntos clave dentro de estas rutas. En estas zonas, es común encontrar diversas especies de cetáceos que utilizan estos corredores para alimentarse y reproducirse.

La alteración de estas rutas puede tener consecuencias graves, como la disminución de poblaciones, la pérdida de biodiversidad y el desequilibrio de los ecosistemas.

Uno de los principales problemas identificados en la actualidad es la coincidencia entre las rutas migratorias de las ballenas y las rutas utilizadas por los buques comerciales. Esta superposición se debe a que ambos sistemas buscan condiciones óptimas: las ballenas siguen corrientes y zonas ricas en alimento, mientras que los barcos utilizan rutas eficientes y seguras.

El resultado es una interacción constante que genera múltiples riesgos, entre los que destacan las colisiones, el ruido submarino y la alteración del comportamiento de las especies.

Impacto del ruido submarino

El ruido submarino es uno de los factores más perjudiciales para las ballenas. Este tipo de contaminación se produce por el funcionamiento de los motores de los barcos y se propaga fácilmente en el agua.

Las ballenas dependen del sonido para comunicarse, orientarse y localizar alimento. Cuando el ruido interfiere con estas funciones, se produce un fenómeno conocido como enmascaramiento acústico, que dificulta su supervivencia.

Riesgo de colisiones

Otro problema importante es el riesgo de colisiones entre embarcaciones y ballenas. Estas colisiones pueden causar lesiones graves o la muerte de los animales, especialmente en zonas de alto tráfico marítimo.

Necesidad de estrategias de protección

Ante estos problemas, se ha vuelto necesario implementar estrategias que permitan reducir el impacto del tráfico marítimo en las rutas de ballenas. En este sentido, los puertos de Vancouver y Prince Rupert han desarrollado programas innovadores que sirven como referencia a nivel internacional y que pudieran ser aplicables para el puerto de Manzanillo y la Laguna de Cuyutlán.

El Puerto de Vancouver como referente en la protección de rutas de ballenas

El Puerto de Vancouver se ha consolidado como uno de los principales referentes internacionales en la implementación de estrategias para la protección de las rutas migratorias de ballenas. Ubicado en la Columbia Británica, Canadá, este puerto opera en una región conocida por su alta biodiversidad marina, particularmente por la presencia de cetáceos como las orcas residentes del sur, ballenas jorobadas y ballenas grises.

La ubicación estratégica del puerto implica una intensa actividad marítima que coincide directamente con rutas migratorias de gran importancia ecológica. Ante esta situación, la autoridad portuaria ha desarrollado diversas iniciativas orientadas a reducir el impacto de sus operaciones sobre estas especies, destacando el programa ECHO (*Enhancing Cetacean Habitat and Observation*).

Origen y objetivos del programa ECHO

El programa ECHO fue creado como respuesta a la preocupación por el deterioro del hábitat de los cetáceos en el mar de Salish. Su objetivo principal es comprender y mitigar los efectos del tráfico marítimo sobre las ballenas, especialmente en lo relacionado con la contaminación acústica y el riesgo de colisiones.

Este programa se basa en un enfoque colaborativo que involucra a múltiples actores, incluyendo autoridades gubernamentales, empresas navieras, científicos, organizaciones ambientales y comunidades indígenas. Esta cooperación permite generar soluciones integrales y basadas en evidencia científica.

Identificación de zonas críticas en rutas de ballenas

Uno de los principales logros del programa ECHO ha sido la identificación de zonas críticas donde coinciden las rutas de navegación y las rutas migratorias de ballenas. Estas áreas representan puntos de alta vulnerabilidad, ya que concentran tanto tráfico marítimo como actividad biológica.

A través de estudios científicos y monitoreo constante, se han delimitado zonas específicas donde se aplican medidas de protección. Esta información es fundamental para orientar las decisiones operativas del puerto.

Reducción de velocidad en zonas de tránsito de cetáceos

Una de las estrategias más efectivas implementadas por el programa ECHO es la reducción voluntaria de la velocidad de los buques en áreas donde se ha detectado la presencia de ballenas.

La disminución de la velocidad tiene un doble efecto positivo:

- Reduce el riesgo de colisiones
- Disminuye el ruido submarino

Diversos estudios realizados en el marco del programa ECHO han demostrado que la reducción de la velocidad de las embarcaciones puede disminuir de manera significativa los niveles de ruido submarino, lo cual contribuye a mejorar las condiciones del hábitat de los cetáceos. En particular, estas investigaciones evidencian que la disminución de la velocidad no solo reduce la intensidad del sonido generado por los buques, sino que también atenúa los efectos del enmascaramiento acústico, favoreciendo la comunicación, orientación y comportamiento natural de las ballenas (Malinka et al., 2023; Vancouver Fraser Port Authority, s.f.). (fuente https://tethys.pnnl.gov/publications/evaluating-benefits-noise-reduction-mitigation-echo-program)

Modificación de rutas marítimas

Otra estrategia clave consiste en la modificación de rutas de navegación para evitar zonas de alta concentración de cetáceos. Aunque esta medida puede implicar ajustes logísticos, su implementación ha demostrado ser altamente efectiva en la protección de las rutas migratorias.

Estas modificaciones se realizan con base en datos científicos y en el monitoreo continuo del comportamiento de las ballenas.

Monitoreo acústico y evaluación de impacto

El programa ECHO utiliza tecnología avanzada para monitorear el ruido submarino y evaluar el impacto de las medidas implementadas. A través de sensores acústicos, es posible medir los niveles de sonido en diferentes áreas y analizar su efecto en las ballenas.

Esta información permite realizar ajustes en tiempo real y mejorar la efectividad de las estrategias de protección.

Resultados del programa ECHO en rutas de ballenas

Los resultados obtenidos han sido significativos. Se ha logrado reducir considerablemente el ruido submarino en zonas críticas, así como disminuir el riesgo de colisiones. Además, el programa ha generado información valiosa sobre el comportamiento de las ballenas, lo que contribuye a mejorar la gestión de las rutas marítimas.

El Puerto de Prince Rupert y su enfoque científico

El Puerto de Prince Rupert representa otro caso destacado en la gestión sostenible de rutas de ballenas. A diferencia de Vancouver, su enfoque se centra principalmente en la investigación científica y el monitoreo en tiempo real, a través del proyecto SWAG (Ships, Whales & Acoustics in Gitga'at Territory).

Este proyecto se desarrolla en el territorio de la comunidad Gitga'at, una región con alta presencia de cetáceos y de gran importancia ecológica.

Objetivos del proyecto SWAG

El proyecto SWAG tiene como objetivo comprender la interacción entre el tráfico marítimo y las ballenas, así como desarrollar herramientas para reducir los impactos negativos.

Entre sus metas principales se encuentran:

- Monitorear la presencia de cetáceos
- Analizar el impacto del ruido submarino
- Prevenir colisiones
- Generar información científica para la toma de decisiones

Tecnología utilizada en el monitoreo de rutas de ballenas

El proyecto SWAG utiliza diversas herramientas tecnológicas avanzadas, como:

- Hidrófonos submarinos
- Sistemas de inteligencia artificial
- Monitoreo en tiempo real
- Observación directa

Estas tecnologías permiten detectar la presencia de ballenas, identificar especies y analizar su comportamiento.

Importancia del monitoreo en tiempo real

El monitoreo en tiempo real permite anticipar riesgos y tomar decisiones inmediatas para proteger a las ballenas. Por ejemplo, si se detecta la presencia de cetáceos en una zona determinada, se pueden ajustar las rutas o velocidades de las embarcaciones.

Participación de comunidades indígenas

Uno de los aspectos más importantes del proyecto SWAG es la participación de comunidades indígenas, quienes aportan conocimientos tradicionales sobre el comportamiento de las ballenas.

Esta colaboración enriquece la investigación científica y fortalece las estrategias de conservación.

Resultados del proyecto SWAG

El proyecto ha permitido mejorar la comprensión de las rutas migratorias y ha contribuido a la implementación de medidas más efectivas para su protección.

Comparación directa entre Vancouver, Prince Rupert y Manzanillo

Al comparar los tres puertos, se observan diferencias importantes en la gestión de las rutas de ballenas.

En Vancouver, se ha adoptado un enfoque basado en la regulación y la modificación de rutas. En Prince Rupert, el enfoque se centra en la investigación y el monitoreo en tiempo real. En contraste, el Puerto de Manzanillo presenta un menor desarrollo en este ámbito.

Limitaciones del Puerto de Manzanillo

El Puerto de Manzanillo enfrenta diversos retos, entre los que destacan:

- Falta de monitoreo en tiempo real
- Ausencia de programas especializados
- Limitada integración de tecnología

Estas limitaciones dificultan la protección de las rutas migratorias.

Impacto ambiental en Manzanillo

El incremento del tráfico marítimo en Manzanillo ha generado presiones sobre el ecosistema marino. La falta de estrategias específicas para proteger las rutas de ballenas aumenta el riesgo de impactos negativos.

Oportunidades de mejora

El puerto tiene la oportunidad de adoptar estrategias similares a las implementadas en Canadá, como:

- Reducción de velocidad
- Monitoreo acústico
- Colaboración científica
- Análisis de las rutas que utilizan los operadores turísticos para el avistamiento de Ballenas en el área

Conclusión de tema 3.3

La comparación entre los puertos de Vancouver, Prince Rupert y Manzanillo evidencia la importancia de integrar la sostenibilidad en la gestión portuaria, especialmente en lo relacionado con la protección de las rutas de ballenas.

Los puertos canadienses han demostrado que es posible reducir el impacto del tráfico marítimo mediante el uso de tecnología, la colaboración interinstitucional y la implementación de medidas específicas.

Por su parte, el Puerto de Manzanillo presenta áreas de oportunidad que podrían ser aprovechadas para mejorar su desempeño ambiental.

De acuerdo al estudio de Tráfico de Marine Traffic se determinarán las principales rutas que hoy en día están utilizando las embarcaciones tanto petroleras, gaseras, de contenedores y de otras cargas para arribar tanto a la laguna de Cuyutlán como al puerto de Manzanillo, por lo que con un cruce de información con los operadores turísticos que operan el avistamiento de ballenas y algunos resultados que presente la Universidad de Colima, se redacten reglas de operación claras que se reflejen en la operación del sistema de tráfico marítimo para recomendar ya sea reducciones de velocidad y cambios de rutas si fuera el caso, mismas que se entregarán en la conclusión de este estudio.

La protección de las rutas migratorias de ballenas no solo es una cuestión ambiental, sino también un desafío global que requiere la participación de múltiples actores.

El futuro de los puertos dependerá de su capacidad para equilibrar el desarrollo económico con la conservación de los ecosistemas marinos.

3.4. Integración de la NOM-131-SEMARNAT-2010 en la La gestión ambiental

La presente Norma Oficial Mexicana establece los lineamientos y especificaciones que deben seguirse en las actividades de observación de ballenas, con el objetivo de garantizar su protección, conservación y la preservación de su hábitat natural. Asimismo, es de carácter obligatorio para todas las personas físicas o morales que realicen estas actividades en aguas de jurisdicción federal de los Estados Unidos Mexicanos (SEMARNAT, 2011, numeral 1).

En este sentido, la NOM-131-SEMARNAT-2010 regula el aprovechamiento no extractivo de las ballenas, es decir, aquellas actividades que permiten la interacción con estos animales sin extraerlos de su entorno, como la observación turística. Sin embargo, la norma también resulta relevante para otras actividades marítimas, ya que establece criterios que buscan minimizar el impacto humano sobre los cetáceos, incluyendo aspectos como la velocidad de las embarcaciones, la distancia de aproximación y el comportamiento de los usuarios (SEMARNAT, 2011).

La importancia de esta norma radica en que las ballenas son especies clave dentro de los ecosistemas marinos y cumplen funciones fundamentales, como el equilibrio de las cadenas alimenticias y la regulación de nutrientes en los océanos. No obstante, diversas actividades humanas, especialmente el tráfico marítimo, generan riesgos como colisiones, contaminación acústica y alteraciones en su comportamiento natural. Por esta razón, la NOM-131-SEMARNAT-2010 se basa en el principio precautorio, el cual establece que, ante la posibilidad de daño ambiental, deben adoptarse medidas preventivas aun cuando no exista certeza científica absoluta (SEMARNAT, 2011, considerandos).

El Puerto de Manzanillo, ubicado en el Océano Pacífico, es uno de los puertos más importantes del país en términos de comercio y movimiento de carga. Debido a la naturaleza de sus operaciones, en el recinto portuario no se desarrollan actividades de observación de ballenas ni es un área donde estas se encuentren de forma constante. Sin embargo, al encontrarse en una región marina donde sí habitan y transitan diversas especies de cetáceos, existe la posibilidad de que estas se encuentren en zonas cercanas a las rutas de navegación.

Por lo anterior, la integración de la NOM-131-SEMARNAT-2010 en la gestión ambiental del puerto no se enfoca en la observación turística, sino en garantizar que las operaciones portuarias se realicen sin afectar a las ballenas ni a su entorno. Actualmente, el puerto opera bajo regulaciones ambientales federales que incluyen la evaluación de impacto ambiental, el cumplimiento de la legislación ambiental vigente y la supervisión por parte de autoridades como la Secretaría de Medio Ambiente y Recursos Naturales (SEMARNAT) y la Procuraduría Federal de Protección al Ambiente (PROFEPA). Estas medidas buscan prevenir la contaminación y proteger el ecosistema marino.

Sin embargo, dichas regulaciones pueden fortalecerse mediante la incorporación específica de los lineamientos de la NOM-131-SEMARNAT-2010. Por ejemplo, el numeral 4.10 establece que, en presencia de ballenas, las embarcaciones deben reducir su velocidad a menos de 5 nudos para evitar colisiones (SEMARNAT, 2011, numeral 4.10). Aunque esta situación no es común dentro del puerto, esta disposición puede aplicarse como un protocolo preventivo en las rutas de acceso y salida, donde las embarcaciones transitan hacia mar abierto.

Asimismo, el numeral 4.11 señala que no pueden coincidir más de cuatro embarcaciones alrededor de una misma ballena o grupo de ballenas (SEMARNAT, 2011, numeral 4.11). Esta medida, aunque está diseñada para actividades de observación, puede adaptarse en el puerto como una forma de evitar la concentración innecesaria de embarcaciones en caso de avistamientos ocasionales.

De igual manera, los numerales 4.12 y 4.13 establecen distancias mínimas de observación y espera entre las embarcaciones y las ballenas. En especies como la ballena jorobada, ballena gris, cachalote, ballena de minke, ballena de sei y ballena de Bryde, la distancia mínima es de 60 metros para embarcaciones menores y 80 metros para embarcaciones medianas o mayores, con una distancia de espera de 240 metros. En el caso de especies de mayor tamaño como la ballena azul y la ballena de aleta, la distancia mínima aumenta a 100 metros y 120 metros, respectivamente, manteniéndose la misma distancia de espera. Estas medidas buscan evitar la perturbación del comportamiento natural de los cetáceos.

En el contexto del Puerto de Manzanillo, estas disposiciones pueden integrarse mediante protocolos de actuación ante avistamientos, en los cuales se establezca que las embarcaciones deben respetar dichas distancias, reducir su velocidad y mantener trayectorias seguras. Esto permitiría prevenir accidentes y minimizar el impacto de las actividades portuarias sobre la fauna marina.

Por otra parte, el numeral 4.19 prohíbe acciones como arrojar residuos al mar, acosar a las ballenas o interferir en su comportamiento (SEMARNAT, 2011, numeral 4.19). Esta disposición es especialmente relevante para el Puerto de Manzanillo, ya que el manejo adecuado de residuos es un aspecto fundamental en su operación. La correcta aplicación de esta medida contribuye directamente a la conservación del ecosistema marino y a la protección de las especies que lo habitan.

Asimismo, el numeral 4.8 establece la importancia de la capacitación del personal en temas de seguridad, salud y ecología (SEMARNAT, 2011, numeral 4.8). En este sentido, el puerto puede implementar programas de capacitación dirigidos a operadores marítimos, tripulación y trabajadores portuarios, con el fin de fomentar una cultura de respeto hacia la fauna marina y promover prácticas responsables.

Además, el numeral 4.9 indica que los usuarios deben ser informados sobre el comportamiento adecuado durante las actividades relacionadas con la observación de ballenas (SEMARNAT, 2011). Aunque esta disposición está orientada al turismo, en el contexto portuario puede adaptarse mediante campañas de concientización ambiental dirigidas a trabajadores y visitantes. El comportamiento adecuado implica que los usuarios y tripulación deben:

* Mantener silencio o bajo nivel de ruido para no alterar a las ballenas.
* No realizar movimientos bruscos dentro de la embarcación.
* No arrojar objetos ni alimentos al mar.
* No intentar tocar, perseguir o acercarse directamente a las ballenas.
* Seguir en todo momento las indicaciones del capitán o guía autorizado.
* Evitar cualquier acción que interfiera con el comportamiento natural de los cetáceos.

A pesar de que el Puerto de Manzanillo ya cuenta con diversas medidas ambientales, como el cumplimiento de regulaciones federales y la supervisión de sus operaciones, aún existe la oportunidad de integrar de manera más específica los lineamientos de la NOM-131-SEMARNAT-2010. Esto permitiría no solo reforzar la protección de las ballenas que pudieran transitar en zonas cercanas, sino también fortalecer la sostenibilidad del puerto y mejorar su imagen ambiental.

En conclusión, la NOM-131-SEMARNAT-2010 representa un instrumento clave para la protección de las ballenas y su hábitat. Aunque en el Puerto de Manzanillo no se desarrollan actividades de observación de ballenas, la integración de esta norma dentro de su gestión ambiental permite adoptar un enfoque preventivo, asegurando que las operaciones portuarias se realicen sin afectar a los cetáceos. De esta manera, se contribuye a la conservación de la biodiversidad marina y al desarrollo sustentable del puerto.

3.5. Análisis del impacto del tráfico marítimo en las rutas de avistamiento de ballenas y evaluación de medidas de mitigación

3.5.1. Las ballenas en Manzanillo: Migración, estudio del tráfico y medidas de protección

INFORMACIÓN SOBRE LA ESPECIE

Las ballenas son algunos de los animales más grandes y complejos del planeta. Estos mamíferos marinos pertenecen al orden de los cetáceos y se caracterizan por su inteligencia, su capacidad de comunicación acústica y sus impresionantes migraciones a lo largo de los océanos. Cada año recorren miles de kilómetros entre zonas de alimentación y reproducción, siguiendo rutas migratorias que conectan diferentes regiones del mundo.

MIGRACIÓN DE LAS BALLENAS

En el puerto de Manzanillo, el Centro de Control de Tráfico Marítimo, alineado con los estándares de IALA, no solo garantiza la seguridad y eficiencia del tráfico marítimo, sino que también desempeña un papel relevante en la mitigación de impactos ambientales, particularmente en la protección de especies como las ballenas dentro de sus rutas migratorias.

- Las migraciones **transoceánicas** de las ballenas están intrínsecamente ligadas a **la estacionalidad de la productividad primaria** en diferentes latitudes.

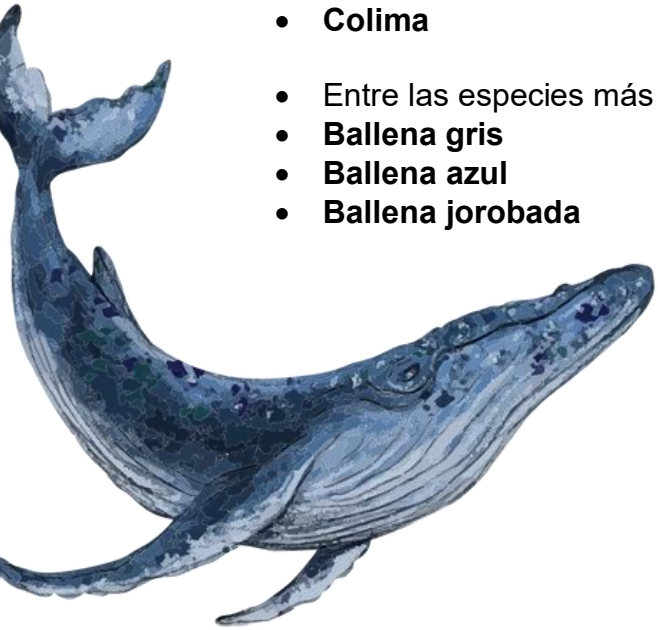
- La estrategia general consiste en desplazarse hacia **aguas frías ricas en nutrientes** durante el verano del hemisferio correspondiente, donde la abundancia de **krill, pequeños peces y zooplancton** permite la alimentación intensiva y la acumulación de reservas de grasa vitales.

- Una vez acumulada suficiente energía, las ballenas emprenden el viaje hacia aguas tropicales o subtropicales más cálidas durante el invierno, donde las temperaturas elevadas son cruciales para el **nacimiento y la supervivencia inicial de las crías.**

MIGRACIÓN DE LAS BALLENAS

- México ocupa una posición geográfica privilegiada dentro de las rutas migratorias del Pacífico. Cada año, entre **noviembre y abril**, varias especies de ballenas llegan a las costas mexicanas para reproducirse y cuidar a sus crías.
- Las principales regiones donde se concentran estos animales incluyen:
- **Baja California**
- **Golfo de California**
- **Oaxaca**
- **Jalisco**
- **Colima**

- Entre las especies más comunes que visitan el país se encuentran:
- **Ballena gris**
- **Ballena azul**
- **Ballena jorobada**



MANZANILLO COMO PUNTO IMPORTANTE EN LA MIGRACIÓN

- La costa de Colima es parte de una ruta migratoria transpacífica. Si bien la presencia de **ballenas jorobadas** es quizás la más conocida en otras zonas de México, las aguas cercanas a Manzanillo son frecuentemente visitadas por especies pelágicas de gran tamaño.
- La zona de Manzanillo, con su **plataforma continental y sus cañones submarinos**, ofrece un hábitat que puede ser utilizado tanto para el **tránsito rápido** como para el **forrajeo temporal**. La migración masiva de presas

pequeñas que acompañan a las ballenas gigantes influye en la permanencia temporal de estos mamíferos.

- A diferencia de las zonas de reproducción más protegidas, los avistamientos en Manzanillo a menudo ocurren en mar abierto, lo que requiere el uso de tecnologías avanzadas como el monitoreo acústico pasivo y el seguimiento satelital para rastrear sus movimientos sin perturbar su comportamiento natural.

MANZANILLO COMO PUNTO IMPORTANTE EN LA MIGRACIÓN

- Investigadores de la Universidad de Colima han monitoreado la presencia de ballenas jorobadas en la región desde aproximadamente 2010 para estudiar su comportamiento y ecología.
- Estas ballenas utilizan las aguas cercanas a Manzanillo principalmente para:

- Apareamiento
- Descanso durante la migración
- Cuidado de crías

- La temporada de avistamiento suele ocurrir entre octubre y abril, siendo diciembre y enero los meses con mayor presencia. Además, estudios científicos han confirmado que estas ballenas migran desde zonas de alimentación en Estados Unidos y Canadá hacia aguas mexicanas para reproducirse.

PUNTOS DE OBSERVACIÓN DE BALLENAS

- En el caso de Manzanillo, la observación de ballenas —principalmente de la especie **ballena jorobada**— ocurre de manera estacional, entre los meses de diciembre y marzo. Las **zonas más comunes de avistamiento** se localizan en:
- La bahía de Santiago
- La bahía de Manzanillo
- Áreas cercanas a Playa Miramar
- Zonas frente a Playa La Audiencia
- Corredores marinos cercanos al puerto interior y exterior

- Es importante destacar que estas áreas coinciden con rutas de navegación de embarcaciones turísticas y, en algunos casos, con tráfico portuario.

AMENAZAS PARA LAS BALLENAS EN MANZANILLO

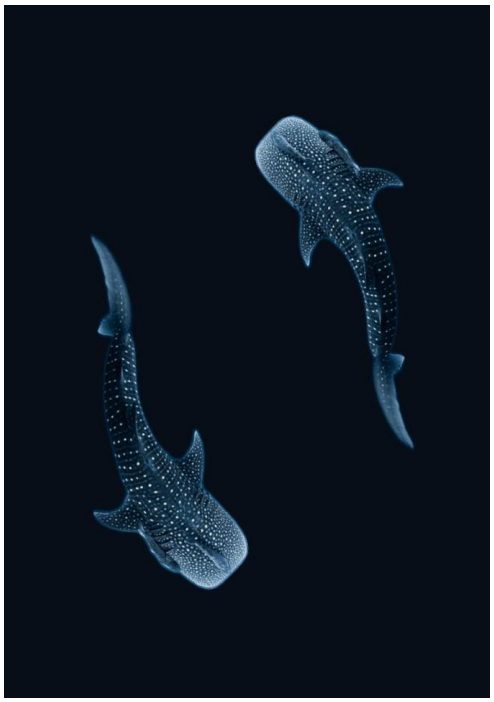
- La actividad humana en Manzanillo, dominada por una **intensa logística portuaria y pesquera**, introduce factores de riesgo significativos para las ballenas migratorias. El tráfico constante de grandes buques mercantes incrementa la probabilidad de colisiones, una de las principales causas de mortalidad no natural en grandes cetáceos a nivel mundial.

- La contaminación acústica generada por el tráfico marítimo puede interferir con la **comunicación y la ecolocalización** de las ballenas, afectando su **orientación durante la migración**. Los esfuerzos de conservación en la región han comenzado a enfocarse en la promoción de buenas prácticas para embarcaciones y la posible implementación de corredores de baja velocidad durante las temporadas pico de migración

AMENAZAS PARA LAS BALLENAS EN MANZANILLO

- Una de las amenazas más palpables y directas en un puerto concurrido como Manzanillo es el tráfico marítimo constante. Los grandes buques de carga y los ferries representan un peligro significativo debido al riesgo de **colisión**.
- La segunda amenaza importante, aunque más insidiosa, es la **contaminación**. Manzanillo genera altos niveles de **contaminación acústica debido al sonar de los barcos, las operaciones portuarias y las actividades sísmicas asociadas a la exploración o infraestructura submarina.** El ruido subacuático interfiere gravemente con **la comunicación, la navegación y la localización de alimento de las ballenas**, que dependen del sonido para interactuar en su entorno. Especies como las **ballenas jorobadas** que utilizan cantos complejos, son particularmente vulnerables a esta perturbación acústica que puede provocar estrés crónico y desorientación.

DAÑOS DE LA CONTAMINACIÓN ACÚSTICA



Las ballenas usan el sonido para poder comunicarse, las crías se orientan con esto ya que imitan el comportamiento de ellas, **los ballenatos dependen completamente de su madre y del sonido para sobrevivir.**

Así como también se utiliza la comunicación de vocalización para el apareamiento de las ballenas. El ruido de motores (hélices, cavitación) ocurre **en las mismas frecuencias que sus vocalizaciones**, por lo que las "tapa".

- **El ruido de lanchas turísticas**

Interfiere con su comunicación, apareamiento y afecta el comportamiento de las ballenas dañando su forma de socializar así como un aumento de estrés obligándolas a abandonar las zonas donde se encuentran, afectando su migración.

DAÑOS DE LA CONTAMINACIÓN ACÚSTICA

- En Manzanillo se ha documentado que el tráfico de embarcaciones:
  - Causa **disturbios en cetáceos**.
  - Afecta su estancia en zonas de reproducción.
  - Las ballenas pueden **abandonar zonas críticas de crianza**.
- **Reduce el éxito reproductivo**
- El ruido crónico produce estrés fisiológico que: Disminuye la reproducción y altera el cortejo y los cantos. Esto es especialmente grave en Manzanillo, donde llegan **a reproducirse**

- **Los ballenatos son los más vulnerables porque:**
- Dependen del sonido para seguir a su madre
- Tienen menor capacidad de escape
- Se cansan más rápido ante el estrés
- Fallas en la lactancia.
- Mayor riesgo de muerte.

DAÑOS DE LA CONTAMINACIÓN ACÚSTICA

- **Nivel de ruido submarino**
- **Datos:**
- Lanchas turísticas: 150–170 dB
- Buques grandes: hasta 180 dB
- **Incluso pequeñas embarcaciones generan niveles de ruido extremadamente altos bajo el agua, cercanos a los de grandes buques**
- **150–180 dB bajo el agua = rango típico de embarcaciones**
- Las ballenas dependen del sonido para:
  - Comunicación
  - Navegación
  - Reproducción

NOM-131-SEMARNAT-2010

- a **NOM-131-SEMARNAT-2010**, establece los lineamientos para la protección de los mamíferos marinos frente a actividades de observación turística.
- Esta norma regula de manera específica la interacción entre embarcaciones y especies como ballenas y delfines, con el objetivo de minimizar impactos físicos, acústicos y conductuales.
- Respecto al **impacto acústico**, aunque la norma no establece un límite en decibeles específico, sí reconoce que el ruido generado por motores fuera de borda —que puede oscilar entre **150 y 170 decibeles bajo el agua**— tiene efectos significativos en los mamíferos marinos.

NOM-131-SEMARNAT-2010

- En cuanto a **distancias y maniobras**, la norma establece que:
- Las embarcaciones deben mantener una **distancia mínima de 60 metros** respecto a los mamíferos marinos.
- En el caso de crías o grupos con comportamiento sensible, esta distancia puede ampliarse hasta **80 metros o más**, dependiendo de la situación.

- Se permite un máximo de **4 embarcaciones simultáneamente** en la zona de observación.
- La velocidad de aproximación no debe exceder los **4 nudos**, y debe realizarse de forma paralela, evitando cambios bruscos de dirección.
- Está estrictamente prohibido perseguir, rodear o interceptar la trayectoria de los animales.
- Por ello, la NOM exige reducir la velocidad, evitar aceleraciones bruscas y minimizar el tiempo de permanencia en la zona de avistamiento.

SANCIONES BASADAS EN LA NOM-131-SEMARNAT-2010

- En materia de **sanciones**, el incumplimiento de esta norma se rige conforme a la **Ley General del Equilibrio Ecológico y la Protección al Ambiente** y demás disposiciones aplicables. Las sanciones pueden incluir:
- **Multas económicas**, que pueden ir desde cientos hasta miles de Unidades de Medida y Actualización (UMA), dependiendo de la gravedad de la infracción.
- **Suspensión temporal o revocación de permisos** para la actividad turística.
- **Aseguramiento de embarcaciones** en casos de reincidencia o daño grave a la fauna.
- Posibles responsabilidades administrativas o incluso penales, si se demuestra afectación directa a especies protegidas.

MITIGACIÓN DE DAÑOS

- i bien la NOM-131-SEMARNAT-2010 establece lineamientos claros, su efectividad depende directamente de la vigilancia ejercida por PROFEPA, SEMARNAT y otras instituciones, así como de la verificación en campo. En zonas como Manzanillo, donde coexisten turismo y actividad portuaria, resulta fundamental fortalecer la inspección, el monitoreo y la participación ciudadana para asegurar su cumplimiento real.
- **Propuestas para Manzanillo:**
- Implementar **límites de velocidad en zonas de ballenas**
- Crear **zonas de exclusión acústica**
- Regular rutas de buques cercanas a áreas de avistamiento
- Monitoreo con hidrófonos **(ruido submarino)**
- Mayor vigilancia por PROFEPA

- Capacitación obligatoria a operadores turísticos

Uno de los ejemplos de protección que se pueden implementar es el programa de protección a ballenas desarrollado en el Puerto de Vancouver, Canadá.

Protección de Ballenas en el Puerto de Vancouver

- El Puerto de Vancouver implementa medidas para proteger a las ballenas, enfocándose en **la reducción del ruido submarino y la prevención de colisiones con embarcaciones.**

- 🐋 **Acciones Principales**

- **Programa ECHO (Enhancing Cetacean Habitat and Observation)**

  - Reducción voluntaria de velocidad de buques

  - Aplicado en zonas clave como el estrecho de Haro y el paso Boundary

  - Disminuye el ruido submarino y el riesgo de impacto

- **Avistamiento Responsable**

  - Empresas turísticas siguen normas estrictas

  - Presencia de guías naturalistas

  - Enfoque en educación ambiental y conservación

Programa ECHO – Protección de Ballenas en Vancouver

- **¿Qué es el Programa ECHO?**

El programa **ECHO (Enhancing Cetacean Habitat and Observation)** fue creado en 2014 por la Autoridad Portuaria de Vancouver para **reducir el impacto del tráfico marítimo en las ballenas**, especialmente las orcas residentes del sur.

- **Objetivos principales**
- Reducir el **ruido submarino** generado por los barcos
- Disminuir el **riesgo de colisiones** con cetáceos
- Proteger zonas clave de **alimentación y tránsito**

Generar **investigación científica** sobre el comportamiento de las ballenas

Programa ECHO – Protección de Ballenas en Vancouver

- **Medidas implementadas**

- **Reducción voluntaria de velocidad**
- Aplicada en áreas críticas del Mar de Salish
- Puede reducir significativamente el ruido submarino
- **Desvío de rutas marítimas:** Evita zonas donde se concentran las ballenas
- **Monitoreo acústico:** Uso de hidrófonos para medir el ruido bajo el agua
- **Colaboración internacional:**Participan científicos, navieras, gobiernos y comunidades

- **Resultados del Programa ECHO**

- Más de **6,000 barcos participantes** en iniciativas voluntarias
- Reducción de hasta **50% del ruido submarino** en zonas clave
- Alta participación: hasta **87% de buques reduciendo velocidad** en algunos periodos

Implementación del programa ECHO en Manzanillo

- El modelo del Programa ECHO demuestra que es posible **equilibrar turismo, economía y conservación**, y puede adaptarse a Manzanillo mediante regulación, tecnología y colaboración.

- **Identificación de zonas críticas**

- Realizar estudios con universidades para ubicar:
  - Rutas de migración
  - Áreas de alimentación y avistamiento
  - Definir **polígonos de protección** en la bahía de Manzanillo

- **Regulación de velocidad (medida clave)**

- Establecer límites de velocidad:
- **<10 nudos** en zonas con presencia de ballenas
- Aplicación:
- Temporada alta (Octubre-Abril)
- Supervisión por Capitanía de Puerto

Implementación del programa ECHO en Manzanillo

- **Control del turismo de avistamiento**

  Crear un **sistema de permisos oficiales** para lanchas

- **Reglas obligatorias:**

  - Distancia mínima (ej. 60–100 m)
  - Máximo de embarcaciones por grupo de ballenas
  - Capacitación certificada para guías

- **Monitoreo en tiempo real**

  Instalar:

  - **Hidrófonos** (ruido submarino)

- Drones o vigilancia costera
- Crear un sistema de alertas para embarcaciones

Implementación del programa ECHO en Manzanillo

- **Incentivos a navieras**

  Descuentos en tarifas portuarias a barcos que:

  - Reduzcan velocidad
  - Cumplan rutas ecológicas
  - Reconocimiento a empresas responsables

- **Coordinación institucional**

  Participación de:

  - SEMARNAT
  - CONANP
  - ASIPONA Manzanillo
  - Sector turístico

Implementación del programa ECHO en Manzanillo

- **Cronograma sugerido**

  Corto plazo (1 año): Regulación de velocidad + normas de avistamiento

  Mediano plazo (2–3 años): Monitoreo acústico + zonas protegidas

  Largo plazo (5 años): Sistema completo tipo ECHO con incentivos y tecnología

  Resultado esperado

- Menos ruido y estrés en ballenas
- Reducción de colisiones

- Turismo más ordenado y sostenible
- Modelo replicable en otros destinos de México

Conclusión: No se trata de copiar ECHO exactamente, sino de **adaptarlo a la realidad local** de Manzanillo con medidas progresivas y colaboración entre sectores.

3.5.2. Directrices revisadas para reducir el ruido submarino radiado debido al transporte marítimo con el fin de abordar sus efectos adversos en la fauna marina de la OMI

Las directrices de la Organización Marítima Internacional (OMI) sobre la reducción del ruido submarino radiado (URN) parten del reconocimiento de que el transporte marítimo constituye una fuente relevante de emisión acústica en el medio marino, particularmente en frecuencias que coinciden con los rangos de comunicación de diversas especies. Este ruido es generado principalmente por la interacción hidrodinámica del buque con el agua, siendo la cavitación de la hélice el mecanismo dominante, así como por la transmisión de vibraciones de la maquinaria hacia el casco y de éste al medio acuático.

El enfoque adoptado por la OMI no establece límites obligatorios, sino que propone un esquema de gestión progresiva del ruido basado en el entendimiento de sus fuentes y en la implementación de medidas de mitigación a lo largo del ciclo de vida del buque. En este sentido, se reconoce que la reducción del ruido es más efectiva cuando se aborda desde la etapa de diseño, mediante la optimización de la forma del casco, la mejora del campo de estela y el diseño de hélices que operen con menor propensión a la cavitación. Estas decisiones permiten reducir de manera significativa la generación de ruido desde su origen, evitando depender exclusivamente de medidas correctivas en operación.

No obstante, las directrices también consideran la realidad de la flota existente, por lo que plantean acciones operativas y de mantenimiento como herramientas clave de mitigación. Entre ellas, destaca la reducción de la velocidad del buque, dado que existe una relación directa entre la velocidad, la carga de la hélice y la intensidad de la cavitación. De igual forma, el mantenimiento adecuado del casco y la hélice, mediante limpieza y control de incrustaciones, contribuye a mejorar las condiciones hidrodinámicas y, por tanto, a disminuir la generación de ruido. La transmisión de vibraciones desde la maquinaria puede reducirse mediante aislamiento adecuado, lo que limita la radiación acústica estructural.

Las directrices también enfatizan que el ruido submarino debe analizarse en función de las condiciones ambientales locales, ya que su propagación depende de factores como la profundidad, la batimetría y las propiedades físicas del agua. Por ello, se propone que la gestión del ruido incluya procesos de evaluación y monitoreo, ya sea mediante medición directa o modelación, con el fin de establecer condiciones base y evaluar la efectividad de las medidas implementadas.

Finalmente, la OMI reconoce que la reducción del ruido submarino no debe considerarse de manera aislada, sino como parte de una estrategia más amplia de sostenibilidad marítima. Existe una sinergia importante con la eficiencia energética, ya que muchas de las medidas que reducen la resistencia hidrodinámica y el

consumo de combustible también disminuyen la generación de ruido. En este contexto, las directrices buscan promover una transición gradual hacia prácticas operativas y de diseño más eficientes y ambientalmente responsables, sin comprometer la seguridad ni la viabilidad económica de las operaciones marítimas.

En este caso específico de Manzanillo se está proponiendo reducir el régimen de máquinas a poca avante, lo cual equivale en promedio a la mitad de la propulsión total del buque.

Las DIRECTRICES REVISADAS PARA REDUCIR EL RUIDO SUBMARINO RADIADO DEBIDO AL TRANSPORTE MARÍTIMO CON EL FIN DE ABORDAR SUS EFECTOS ADVERSOS EN LA FAUNA MARINA se encuentran en el anexo “3.5 OMI - Revised Guidelines For The Reduction Of Underwater Radiated Noise” en inglés y en el anexo “3.5 OMI - Directrices Revisadas Para Reducir El Ruido Submarino Radiado Debido al Transporte Marítimo” en español.

4. Informe de recomendaciones para la modificación de las reglas de operación de la ASIPONA Manzanillo orientadas a la mitigación del impacto acústico en ballenas

Medidas de mitigación de ballenas y ballenatos en la laguna de Cuyutlán que deben ser incluidas en las reglas de operación, que se elaboren en general para el puerto de Manzanillo, pero específicamente para las embarcaciones que transiten hacia la laguna de Cuyutlán, es decir, el nuevo puerto de Manzanillo:

1. En términos generales: Queda prohibida toda actividad sísmica asociada a la exploración o infraestructura submarina, a menos que sea autorizada por la Comisión Nacional de Energía, CONAPESCA, y SEMARNAT en sus respectivos ámbitos de regulación.
2. Regla 42: Que las diferentes velocidades en las diferentes zonas de tráfico, la velocidad máxima será la ahí expresada, sin embargo, se debe de considerar que el régimen de máquina máximo será el de poca avante, lo que normalmente equivale a la mitad del régimen máximo de propulsión del buque.
   De acuerdo a la recomendación 6.23 Ship Speed de las recomendaciones de la OMI en las DIRECTRICES REVISADAS PARA REDUCIR EL RUIDO SUBMARINO RADIADO DEBIDO AL TRANSPORTE MARÍTIMO CON EL FIN DE ABORDAR SUS EFECTOS ADVERSOS EN LA FAUNA MARINA. Toda embarcación mayor de 500 Unidades de Arqueo Bruto de Registro, cuyo destino sea ya sea el antiguo de Manzanillo o la Laguna de Cuyutlán, al encontrarse a una distancia de 10 millas de las respectivas boyas de recalada, deberán de reducir su régimen de máquinas a poca avante con la finalidad de disminuir ruido del sistema de máquinas de la embarcación y evitar posibles colisiones con los mamíferos. Esto se debe discutir con el cuerpo de pilotos del puerto de Manzanillo.

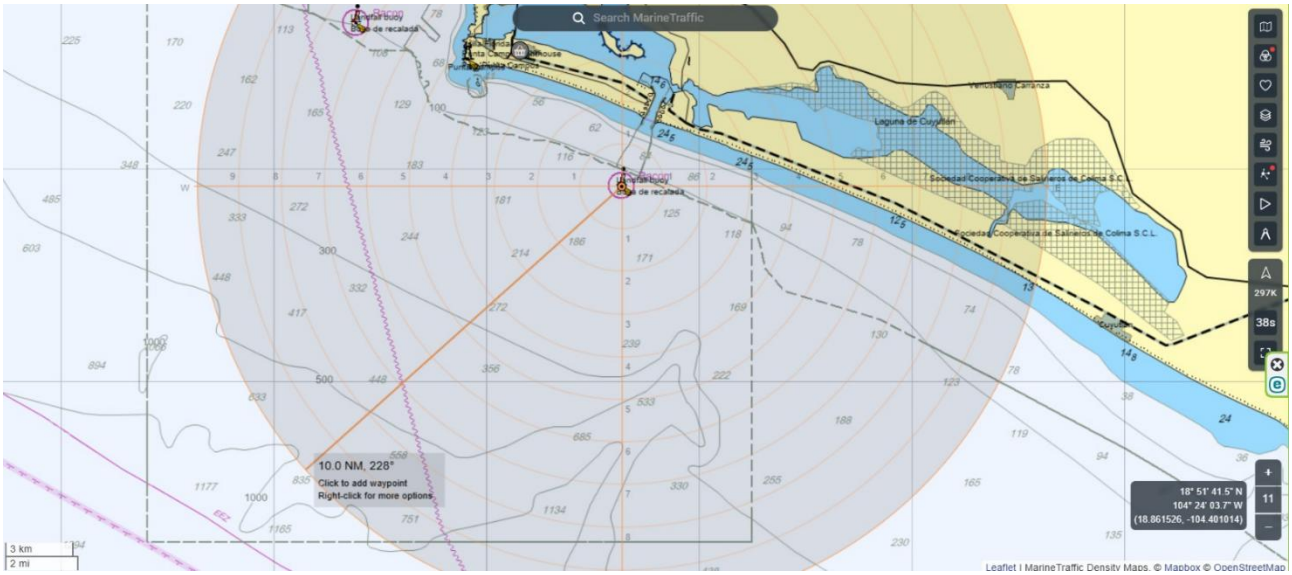

Figura 4-1. Zona de reducción de régimen de máquina

3. Una vez que se entre al radio de las 10 MN deberá haber un vigía con prismáticos para captar el avistamiento de ballenas en riesgo de colisión con la embarcación.
4. Notificación de accidentes: Toda embarcación mayor a 100 Unidades de Arqueo Bruto, en caso de haber tenido una colisión con ballenas, deberá reportarlo inmediatamente a la Capitanía de Puerto donde informe las condiciones de la colisión y las medidas de mitigación y maniobra de evasión para evitar la misma.
5. Optimización del asiento y el calado del buque puede reducir la potencia necesaria y, por tanto, el ruido de cavitación de la hélice. Deberá de hacerse un cálculo para que el asiento tenga un promedio de un diferencial de 2 pies entre el calado de proa y el calado de popa para embarcaciones tipo MR de 180 m y de 1.5 pies por lo menos para embarcaciones mayores de 200 m de eslora.
6. Ajustar y optimizar la ruta del buque, la velocidad y el tiempo de navegación para reducir el tiempo que esté fondeado y el ruido submarino radiado en puerto y zonas costeras.

5. Conclusiones

Con base en el análisis de tráfico marino y las condiciones operativas proyectadas para la Laguna del Vaso II en el Nuevo Puerto Laguna de Cuyutlán, se concluye lo siguiente:

1. **Aplicación en reglas de operación**
   El estudio constituye un insumo técnico fundamental para la elaboración y/o actualización de las reglas de operación de las terminales ubicadas en la Laguna de Cuyutlán, permitiendo establecer criterios que optimicen la gestión del tráfico marítimo bajo condiciones seguras y eficientes.
2. **Sustento para la evaluación ambiental (MIA)**
   Los resultados obtenidos permiten estimar los volúmenes de dragado requeridos para garantizar condiciones operativas óptimas, así como identificar medidas de prevención y mitigación ambiental alineadas con los Anexos I a VI del Convenio MARPOL, contribuyendo al desarrollo de la Manifestación de Impacto Ambiental correspondiente.
3. **Apoyo al análisis de maniobrabilidad**
4. El estudio proporciona información relevante para la evaluación de maniobrabilidad de embarcaciones de gran porte, particularmente en lo relativo al dimensionamiento de las áreas de navegación y la determinación del claro bajo quilla (UKC), elementos clave para garantizar la seguridad de la navegación.
5. **Insumo para análisis estratégicos**
6. La información generada podrá ser utilizada como base parcial en la elaboración de análisis FODA y otros estudios estratégicos asociados al desarrollo portuario.
7. **Determinación de requerimientos de dragado**
   Se establece la necesidad de desarrollar un canal de navegación con una plantilla de:
   - **250 m en la zona de acceso**, y
   - **200 m en las áreas correspondientes a las terminales TEC 2 y 3 y TEC 4,5 y 6.** con una **profundidad de proyecto de 18.5 m**.
     A partir de la comparación entre la batimetría actual y la sección de diseño propuesta, se deberá determinar el volumen total de material a dragar, expresado en metros cúbicos (m^3), así como definir las zonas de disposición final del material (zonas de tiro) o su posible aprovechamiento en zonas de relleno, conforme a criterios técnicos y ambientales aplicables.
8. **Integración en la planeación portuaria**
   En conjunto, los resultados del estudio contribuyen a la planeación integral del Nuevo Puerto Laguna de Cuyutlán, al vincular la operación marítima, el diseño de infraestructura y la gestión ambiental bajo un enfoque de seguridad, eficiencia y sostenibilidad.

9. Dada la conformación de la flota mundial, y los movimientos históricos del puerto en las condiciones actuales, nos lleva a la conclusión de que el puerto tiene la posibilidad de crecer un 300% lo que implica que el puerto de Manzanillo pudiese considerarse como un puerto HUB en América que le de servicio tanto para la navegación inter-Pacífica como el movimiento intra-regional o navegación de corta distancia, en este sentido, el puerto de Manzanillo pudiese estar apoyando el desarrollo de trans-oceánico, es decir, una navegación de corta distancia de Manzanillo a Salina Cruz para así enviar contenedores de Salina Cruz a Coatzacoalcos y posteriormente a puertos del Golfo tanto en cabotaje como en corta distancia entre puertos de México y Estados Unidos. Y por otro lado se puede fortalecer la distribución intra-regional entre el Puerto de Manzanillo combinado con puertos de Estados Unidos en el Pacífico como son Los Ángeles y San Diego, Centro América en puertos como son Guatemala, Panamá, Puerto Rico, entre otros y Sud-América como son Colombia, Perú y Ecuador.

1.0 INTRODUCCIÓN

El Proyecto Arquitectónico de Redimensionamiento, Actualización y Optimización Conceptual del Puerto Nuevo Manzanillo–Cuyutlán se inscribe en el proceso de transformación estructural del sistema portuario mexicano ante el crecimiento sostenido del comercio marítimo internacional y la consolidación de Manzanillo como principal nodo contenerizado del país.

La ampliación hacia la Laguna de Cuyutlán representa una intervención de alta complejidad técnica, dada la naturaleza lagunar del entorno, la exposición a fenómenos meteorológicos extremos del Pacífico oriental y la interacción dinámica entre procesos oceánicos, mareales y sedimentológicos. En este contexto, el conocimiento detallado de las condicionantes físicas y ambientales no constituye un insumo accesorio del proyecto, sino la base estructural sobre la cual deben definirse los criterios de diseño, seguridad y operación de la nueva infraestructura.

El presente informe tiene por objeto caracterizar y analizar de manera integral los factores climáticos, oceanográficos, hidrodinámicos y sísmicos que inciden en la zona de proyecto, estableciendo los parámetros técnicos necesarios para el dimensionamiento seguro y eficiente de las futuras terminales, estructuras de contención y obras marítimas asociadas. El entendimiento de estos procesos es indispensable para garantizar la resiliencia del sistema ante eventos extremos, optimizar el comportamiento hidráulico de la laguna y asegurar la viabilidad técnica de la expansión portuaria.

2.0 OBJETIVOS.

2.1 Objetivo Principal.

El objetivo principal de los servicios descritos en el presente documento es:

- Desarrollar el análisis técnico de las condicionantes físicas y medioambientales que inciden en la zona de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán, con el propósito de establecer los parámetros de diseño y operación que aseguren la funcionalidad, seguridad estructural y sostenibilidad de la infraestructura proyectada..

2.2 Objetivos Particulares.

Los objetivos particulares de los servicios descritos en el presente documento son:

- El estudio busca caracterizar el régimen climático regional, incluyendo temperatura, precipitación y vientos dominantes, así como realizar el análisis probabilístico de eventos extremos asociados a huracanes y tormentas tropicales. Asimismo, se propone evaluar el comportamiento del oleaje normal y extremal, la dinámica de corrientes exteriores e interiores de la laguna, la marea astronómica y la posible incidencia de tsunamis en la zona de influencia del proyecto.

- De manera complementaria, el informe tiene como finalidad definir las solicitaciones físicas que deberán considerarse en el diseño de estructuras marítimas y de contención de rellenos, garantizando que el proyecto ejecutivo incorpore criterios de seguridad compatibles con periodos de retorno adecuados y estándares internacionales de ingeniería portuaria.

3.0 CONDICIONANTES FÍSICAS Y MEDIOAMBIENTALES.

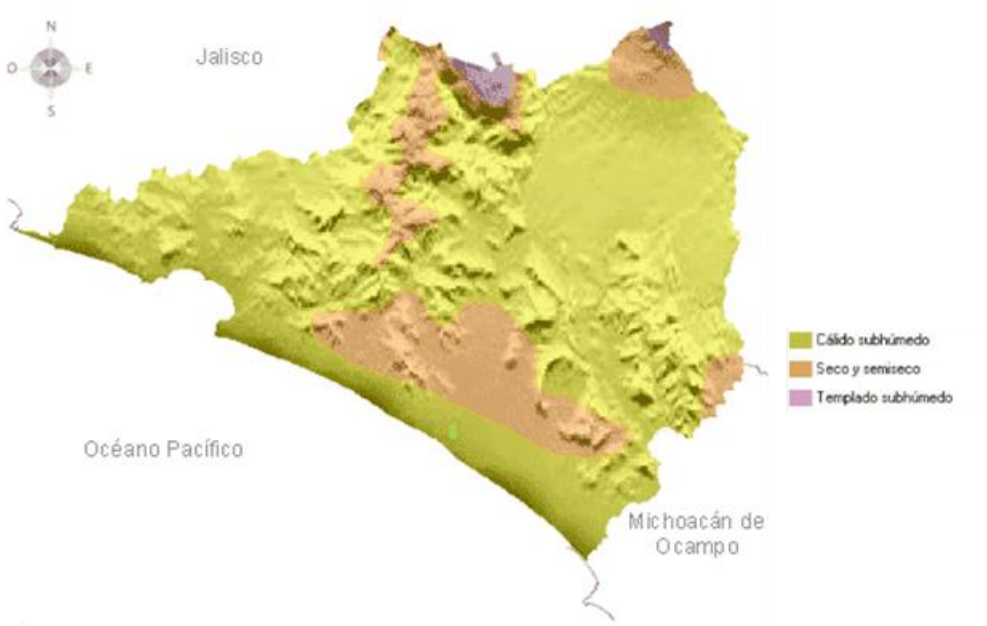
El conocimiento y comprensión del comportamiento de los aspectos físicos en la zona de estudio es esencial para el desarrollo del presente proyecto.

3.1 Clima.

El clima que impera en la región es tropical lluvioso; se considera que la temporada de lluvias corresponde a los meses de junio a octubre; siendo septiembre el mes más lluvioso debido a los frecuentes ciclones durante este mes (Rzendowski, 1978). Como resultado de los procesos climáticos, el número de días despejados es en promedio de 137 al año, y el promedio de días nublados de 116 según los reportes meteorológicos del Instituto Oceanográfico de Manzanillo. El promedio anual de humedad relativa es del 75%, siendo el mes de septiembre, el que alcanza mayor humedad, con un promedio de 82% (semar, 1989).

Esta región se caracteriza según la clasificación de Köppen modificada por Enriqueta García (1964), como del tipo Awo(w)i, que corresponde a un clima tropical cálido subhúmedo, el más seco de los subhúmedos por presentar una precipitación en el mes más seco menor de 60 mm, correspondiendo en promedio a cinco milímetros para el caso de Manzanillo (Carta de Climas del INEGI, 1980).

Figura 3.1 Clima en la Zona de Proyecto**.**



Fuente: Elaboración con base en INEGI, Carta de Climas 1:1,000,000**.**

3.2 Temperatura.

La temperatura media mensual para el sistema ambiental regional en los meses más cálidos son julio y agosto con 28.5°C y de diciembre a abril, los meses más fríos, con 25°C; en el mes más frío se ha registrado una temperatura media de 20°C (Cruz et al., 1988); la temperatura anual promedio es de 25°C con una oscilación de 10°C (Cruz et al., 1992). La Carta de Temperaturas Medias Anuales del INEGI (1980), reporta un rango de temperatura de 26°C a 28°C.

Los registros de las Normales Climatológicas de Temperatura para el Puerto de Manzanillo en la serie 1981-2000 se presentan en la Tabla 3.1.

Tabla 3.1 Normales Climatológicas de Temperatura para el Puerto de Manzanillo.

3.3 Precipitación.

La evaluación de la lluvia en su comportamiento como fenómeno extraordinario se ha realizado a partir del cálculo de probabilidades de ocurrencia, con base en datos de lluvia máxima en 24 h registrados en estaciones meteorológicas.

La Secretaría de Recursos Hidráulicos llevó a cabo un estudio a nivel nacional regional, del cual resultó publicado un boletín donde se muestra gráficamente la distribución de isoyetas, basada en la ocurrencia de tormentas máximas observadas y probables en 24 h (SARH, 1976). En dicho trabajo se consideraron ocho diferentes períodos de retorno, desde 2 hasta 10,000 años. Se utilizó el método Hershfiel para la estimación de las frecuencias de las tormentas máximas probables (en 24 h), en los períodos de retorno mencionados, con base en datos de 2,600 estaciones (Hershfield, 1963).

El promedio anual de la precipitación máxima para el Puerto de Manzanillo es de 766.4 mm en la serie de 1981 a 2000. Los valores de los promedios mensuales de la precipitación

máxima y máxima en 24 horas para el Puerto de Manzanillo de acuerdo a las Normales Climatológicas de la serie de tiempo de 1981 a 2000 del Observatorio Sinóptico del Servicio Meteorológico Nacional de la Comisión Nacional del Agua (CONAGUA) se presentan en la Tabla 3.2

Tabla 3.2 Promedios Mensuales de Precipitación Máxima y Máxima en 24 horas para el Puerto de Manzanillo.

3.4 Vientos.

Como parte importante de este estudio está la recopilación y análisis de datos de viento. Se puede afirmar que el régimen de vientos de la República Mexicana está influido por las masas de aire del Océano Atlántico, Océano Pacífico y las de alta atmósfera, siendo estas dos últimas, las que afectan de manera importante el área de proyecto. El viento es el factor meteorológico más importante en el interior del canal de acceso y en las dársenas de ciaboga y operativa del muelle.

La información utilizada procede de una base de datos de viento correspondiente a las medidas de viento de la Estación de Manzanillo, en el periodo del 2 de septiembre de 2008 al 11 de enero de 2012, de la cual se extrae la tabla de distribución de dirección y velocidad del viento (ver Tabla 3.3).

3.4.1 Probabilidad de Excedencia.

En la Figura 3.2 se muestra la probabilidad anual de excedencia de velocidades de viento sostenidas. Estos valores se encuentran resumidos en la Tabla 3.4. Las velocidades con un 90% de ser excedidas es de 5.0 m/s, con 75 % la velocidad es 4.5 m/s, con un 50% de ser excedidas un 4.0 m/s con un 25% de ser excedidas de 1.5 m/s.

3.4.2 Rosa de viento.

Considerando como base la información de vientos citada, fue realizado el análisis y acondicionamiento de la información de viento. El procesamiento de dicha información permite identificar las direcciones y magnitudes con las que actúa el viento anualmente en la zona del proyecto, quedando ilustradas en frecuencia, magnitud y dirección, en la Rosa de Vientos (ver

Figura 3.3). Asimismo, se presentan los histogramas de números de eventos por rachas de vientos por magnitud de velocidad sostenidos y dirección.

Tabla 3.3 Frecuencia de Vientos Máximos.

Figura 3.2 Clima en la Zona de Proyecto.

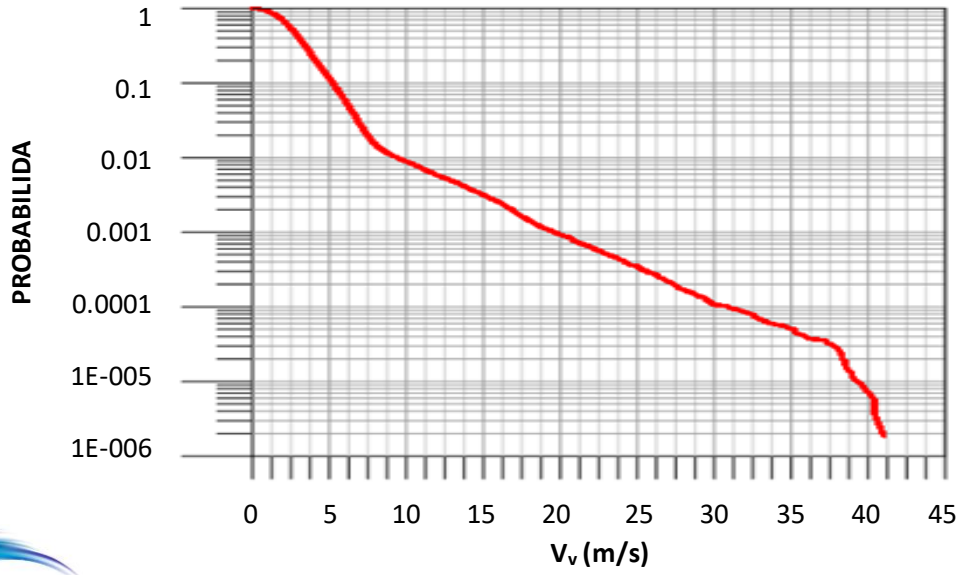

Tabla 3.4 Velocidades Sostenidas Asociadas a una Probabilidad de Excedencia.

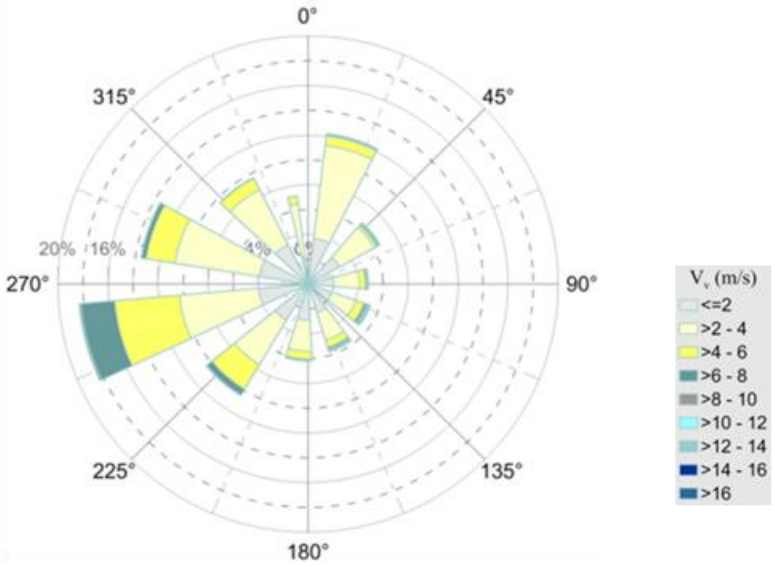
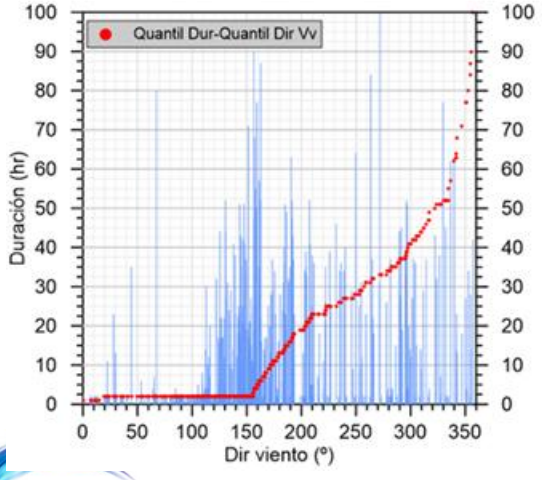
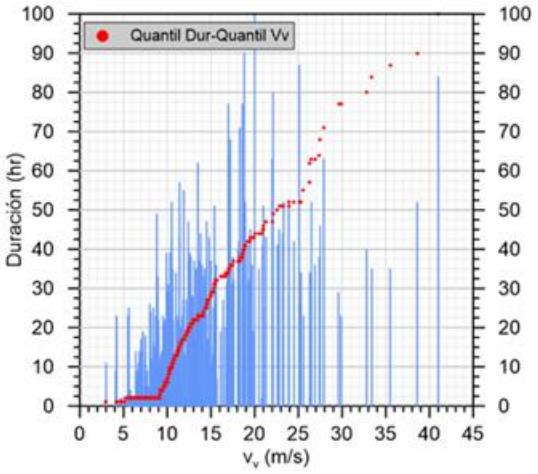
Probabilidad de Excedencia (%)	V (m/s)	Denominación
90	5.0	Flojo (brisa débil)
75	4.5	Flojo (brisa débil)
50	4.0	Flojo (brisa débil)
25	1.5	Ventolina

Figura 3.3 Rosa de Vientos Anual (1949-2018).







Las direcciones anuales que se presentan en la rosa de vientos, se muestra la rosa de velocidad sostenida de viento anual, en dicha figura este apartado se presentan las rosas de vientos (hacia donde van). Todas las direcciones tienen probabilidad de ocurrencia, sin embargo, las gobernantes son WNW, WSW y NNE, las velocidades mayores se presentan provenientes del WSW.

La velocidad media anual de los vientos es de 5 m/s. Los vientos dominantes en condiciones normales proceden del Nor-Noreste, con velocidad promedio de 1.5 m/s y del Oeste al Oeste – Suroeste, con velocidad promedio de 5.0 m/s.

3.4.3 Análisis Extremal de Viento.

En esta sección se presenta el análisis extremal realizado con el papel probabilístico de Weibull (ver Figura 3.4) para extremos de velocidades sostenidas del viento. Este análisis nos permite obtener las velocidades de viento asociadas a un periodo de retorno, que se relaciona con una probabilidad de ocurrencia.

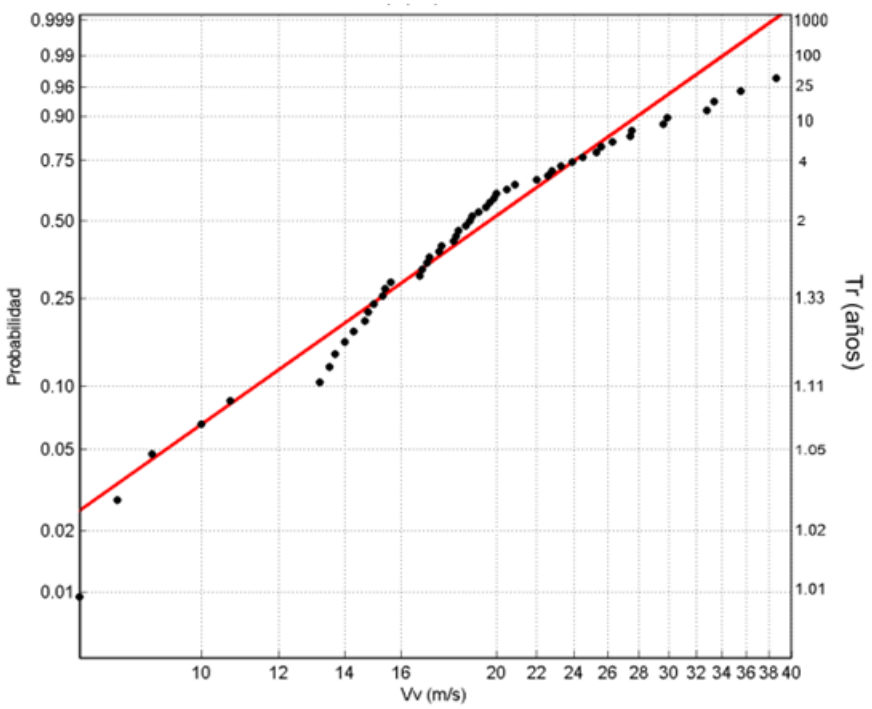
Para realizarlo se seleccionan de cada año la velocidad sostenida mayor presentada, es decir, se tienen 60 velocidades de máximas anuales y con ellas se representan el papel probabilístico. Los puntos negros son los datos reales de la serie de datos y la línea roja representa el ajuste de Weibull. En el eje e izquierdo se presenta la probabilidad de ocurrencia y en el eje y derecho el periodo de retorno en años. El eje x representa los valores de velocidades sostenidas de viento en m/s.

Tabla 3.5 Velocidades Sostenidas de Viento Asociadas a Periodos de Retorno.

Tr (años)	Vv (m/s)	Régimen de viento
2	20.0	Temporal
5	25.0	Temporal duro
10	28.0	Temporal duro
25	28.5	Temporal muy duro
50	33.0	Temporal huracanado
100	34.0	Temporal huracanado

De acuerdo con el análisis desarrollado se observa que, para un período de retorno de 50 años, la velocidad de viento sostenido corresponde a 33 m/s.

Figura 3.4 Análisis Extremal de Viento Papel Probabilístico de Weibull**.**



3.5 Oleaje Normal.

El oleaje es una de las condiciones marítimas de mayor influencia en la zona litoral, por tal motivo, se establece la necesidad de conocer cuál es el comportamiento del oleaje en condiciones ordinarias (oleaje normal) y extraordinarias (oleaje ciclónico).

El oleaje frecuente o normal es aquel que incide periódicamente y bajo condiciones normales en la zona de interés. Para este caso, también deben identificarse dos fuentes generadoras de oleaje normal: el oleaje completamente desarrollado en alta mar (swell), generado por vientos lejanos que soplan sobre la superficie del mar, y al oleaje asociado a vientos locales, desarrollado dentro de un campo de generación limitado por distancia y como consecuencia de la existencia de barreras naturales contra el oleaje distante.

La fuente de datos de oleaje utilizada proviene de los reanálisis climáticos realizados por The Copernicus Climate Change Service (C3S) el cual proporciona información autorizada sobre el clima pasado, presente y futuro en Europa y el resto del mundo a partir de un reanálisis climático

que combina observaciones pasadas con modelos para generar series temporales consistentes de múltiples variables climáticas que proporcionan una descripción completa del clima observado a medida que ha evolucionado durante las últimas décadas, en cuadrículas 3D a intervalos sub-diarios.

El nodo utilizado en el presente apartado corresponde a:

- ERA5-02 (18.5° N, 104.5° W)

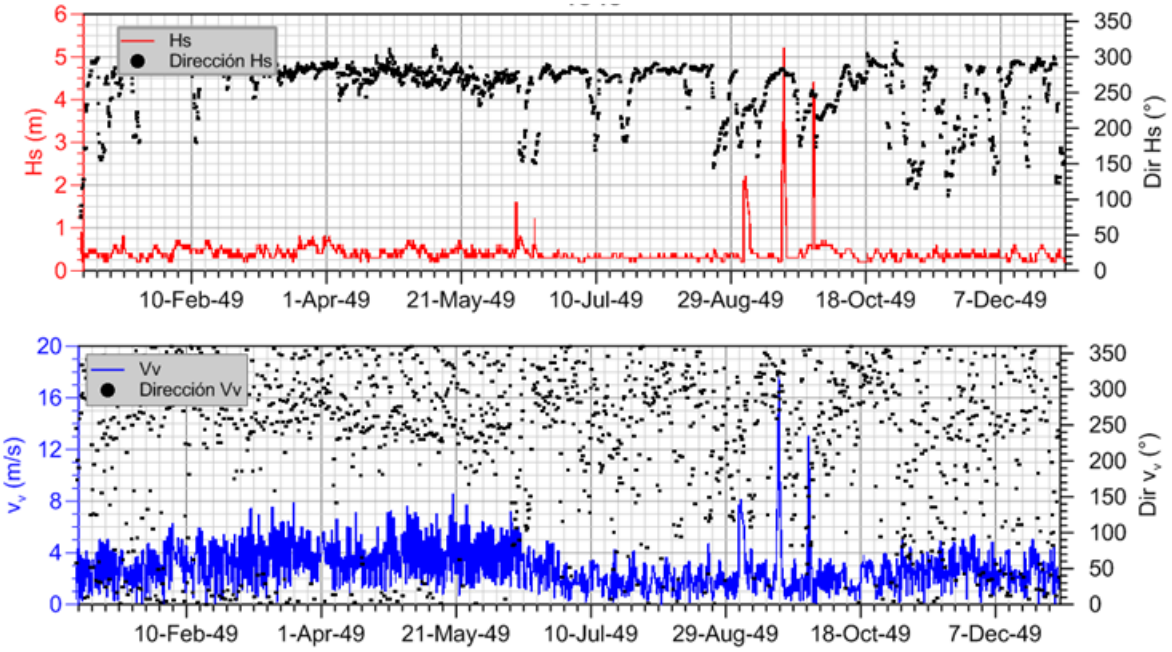
Se cuenta con 187,704 estados de mar con datos en formato ASCII para un periodo de 21 años, con datos que abarcan desde el 1 de enero de 1998 hasta el 31 de mayo del año 2019, ver Figura 3.5.

Figura 3.5 Localización del Nodo de Oleaje ERA5-02**.**

Considerando como base la información de oleaje y siguiendo las actividades particulares del presente estudio se realizó una revisión grafica de la información contenida en las bases de datos. Dicha información consiste en la graficación de los estados de mar para revisar año con año que la información contenida no contenga picos o anomalías o irregularidades que representen alguna variabilidad no común y que durante el procesamiento de la información resulte en la generación estadística y probabilística poco confiable o no representativa de las condiciones de los procesos físicos que ocurren en la zona de interés.

A manera de ejemplo se presenta el grafico de la revisión de los estados de mar (oleaje y viento) de las series de datos contenida en la información recopilada, Figura 3.6.

Figura 3.6 Estados de Mar (Oleaje y Viento) de las Series de Datos Contenida en el Nodo de Información ERA5-02**.**



En la rosa de oleaje anual, para los nodo de información con 21 años de registro, en la Figura 3.7 se presentan las direcciones (de dónde viene) el oleaje. Presenta una dirección gobernante SSW con un 45% de probabilidad de ocurrencia con alturas de ola asociadas entre 1.0 y 2.5 m. Seguida por las direcciones SW y WSW con un 24 y 15% de probabilidad de ocurrencia.

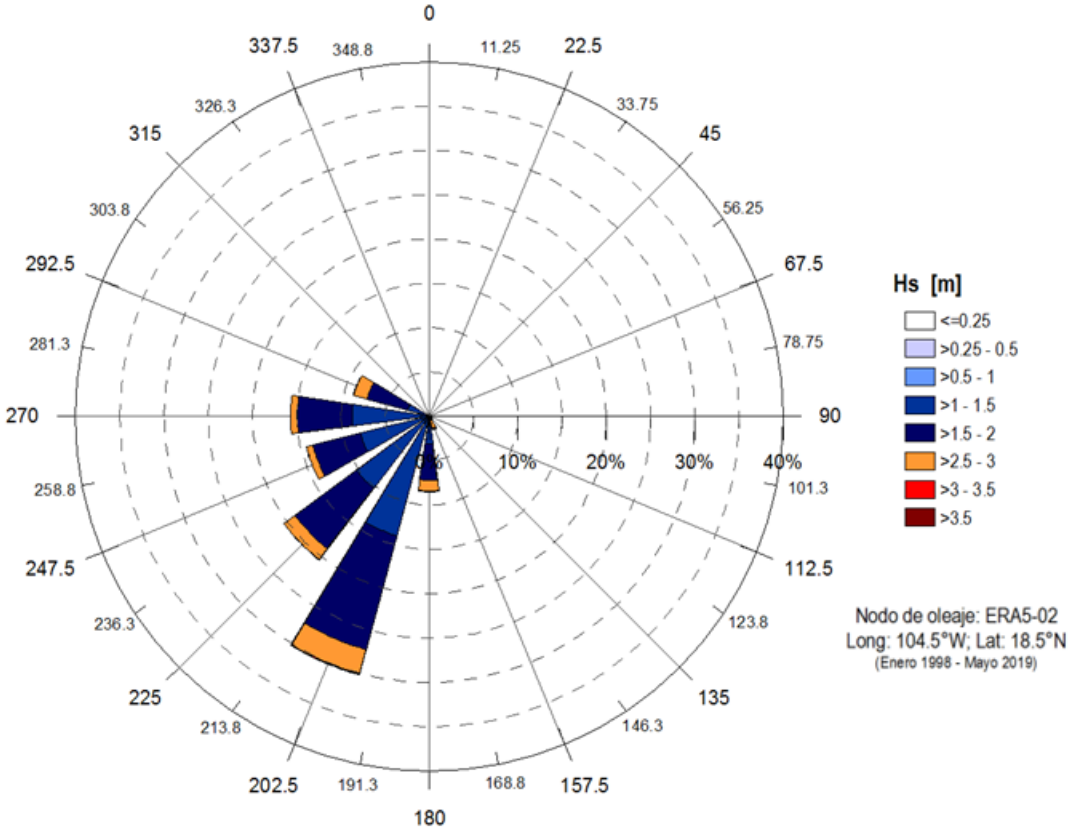
Los valores de probabilidad asociados a cada dirección y alturas de ola significantes se presentan en la Tabla 3.6.

Tabla 3.6 Valores de Altura de Ola con Probabilidades de Excedencia y sus Periodos Asociados.

Probabilidad de Ocurrencia (%)	Direcciones	Alturas de Ola Asociada (m)
44	SSW	1.0 - 2.5
24	SW	1.0 - 2.5
15	WSW	1.0 - 2.5
10	W Y WWN	1.0 - 2.5

7	S	1.0 - 2.5

Figura 3.7 Rosa de Oleaje Anual**.**



Fuente: Elaboración propia; con base en la serie de datos del ERA5.

3.6 Corrientes.

3.6.1 Corriente Exterior a la Laguna.

Las corrientes superficiales en invierno mostraron una tendencia hacia el Noroeste y Oeste así como dos convergencias frente a los Ríos Marabasco y Río Armería generalmente. El valor promedio de la velocidad fue de 0.60 nudos, ver Figura 3.8.

La circulación superficial en primavera se dirigió hacia el Noroeste y Oeste así como un flujo perpendicular a la costa frente a las Bahías de Manzanillo, los Ríos Armería y Coahuayana. El valor promedio de la velocidad fue de 0.53 nudos, ver Figura 3.9.

Figura 3.8 Corrientes Superficiales en el Mar Territorial del Estado de Colima (12-17 de Febrero)**.**

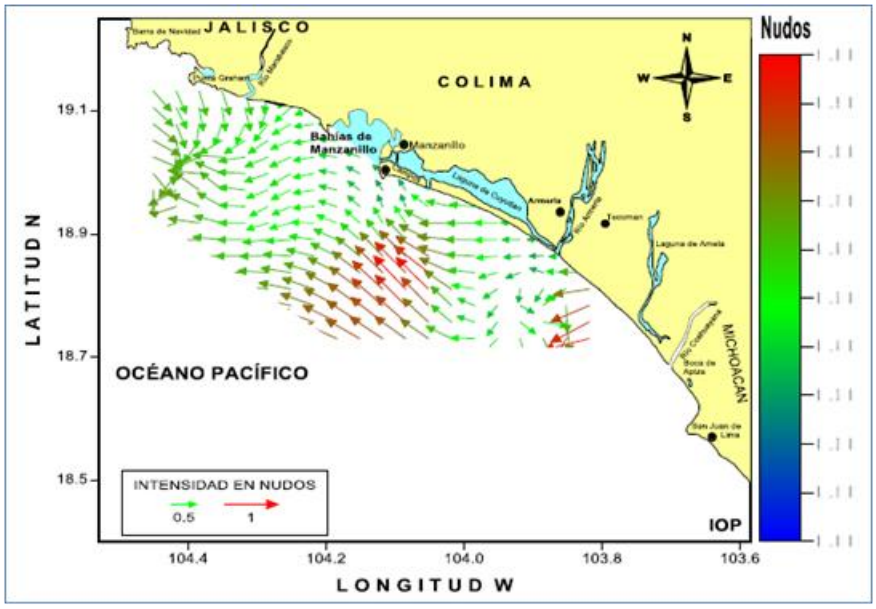


Figura 3.9 Corrientes Superficiales en el Mar Territorial del Estado de Colima (8-13 de Mayo)**.**

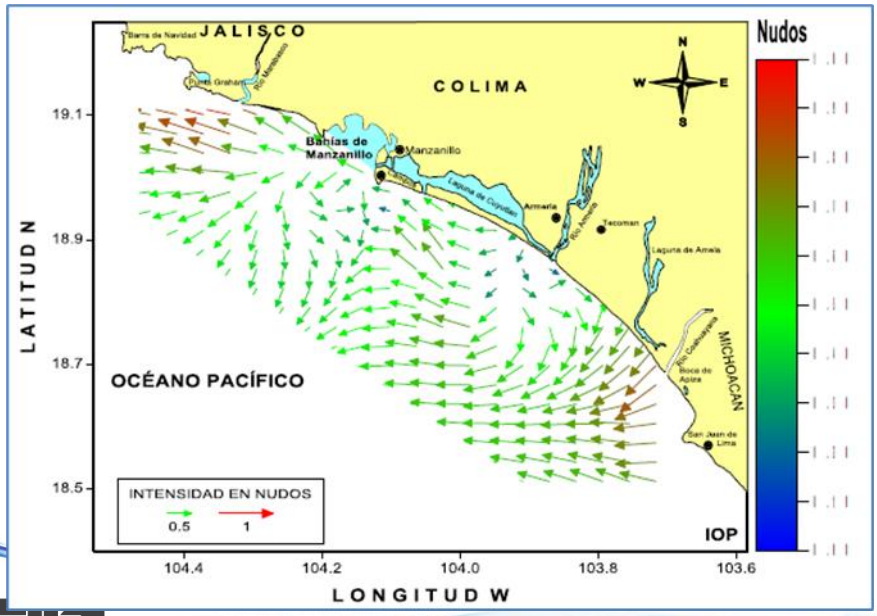
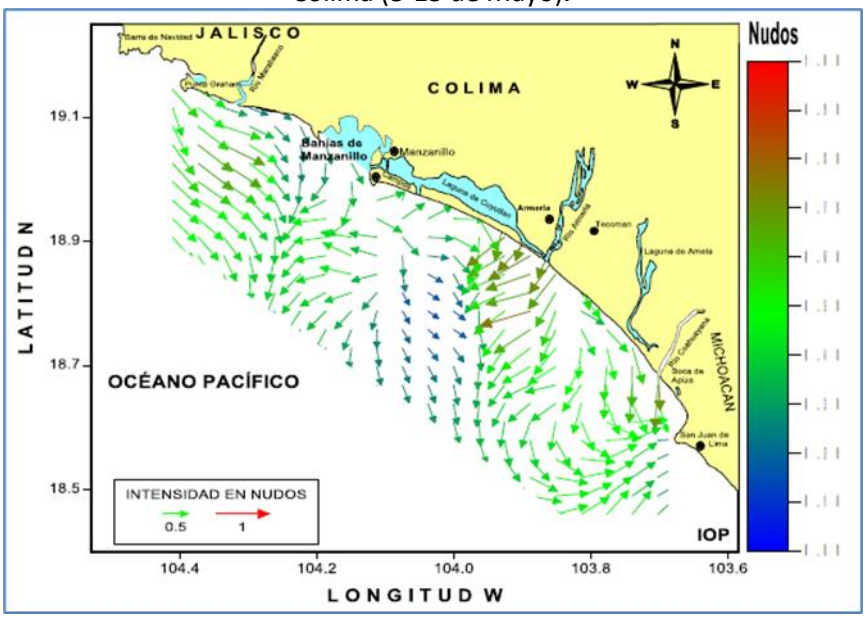


La dinámica superficial en verano presento dos zonas de convergencia hacia mar adentro: una frente a las Bahías de Manzanillo y otra frente a la Laguna de Cuyutlán. También la existencia de un flujo hacia la costa de San Juan de Alima, Michoacán. El valor promedio de la velocidad fue de 0.43 nudos, ver Figura 3.10.

Figura 3.10 Corrientes Superficiales en el Mar Territorial del Estado de Colima (8-13 de Mayo)**.**



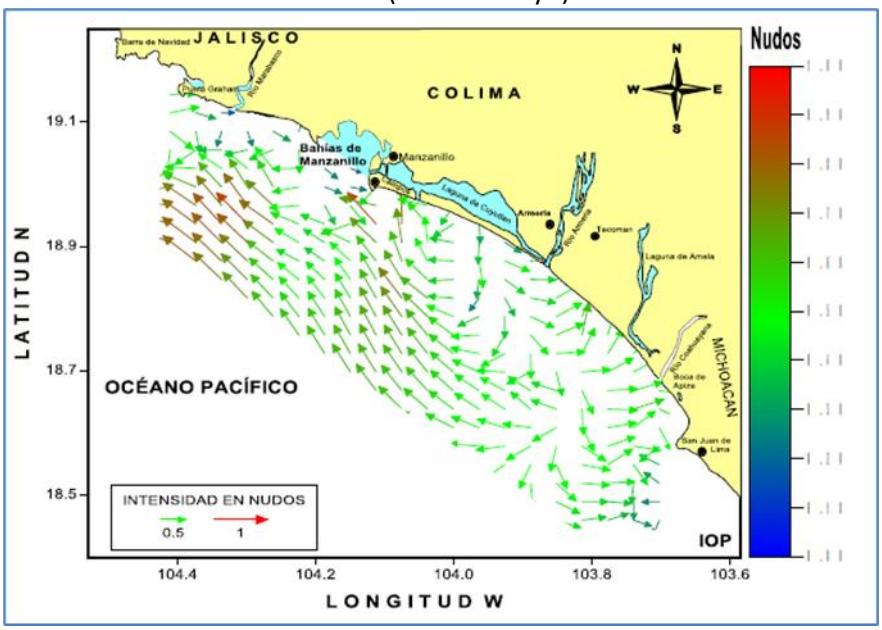
La dirección del movimiento de las aguas superficiales en otoño es muy irregular para las estaciones cercanas a la costa. El flujo en las estaciones más alejadas de la costa (oceánicas), se dirigen hacia el Noroeste (paralelas a la costa) generalmente. El valor promedio de la velocidad fue de 0.48 nudos, ver Figura 3.11.

De acuerdo con lo anterior, las corrientes son paralelas a la costa, en los dos sentidos, y completamente transversales al canal de acceso. La intensidad máxima de la corriente observada[1]

[1] De acuerdo con la conversación con los Pilotos de Puerto se ha confirmado la presencia de la corriente longitudinal a la costa. Asimismo, se comentó que en ocasiones la dirección de la corriente varía significativamente entre la recalada y el canal de acceso. Para conocer la corriente cerca del canal de acceso emplean una embarcación menor para determinar la corriente al dejar la misma a la deriva, ya que no se dispone de mayor información ni elementos de medida de la corriente

es de 2.50 nudos, y esta se presenta tras un fuerte temporal, y la mínima de unos 0.20 nudos. La velocidad de corriente, de forma general, suele encontrarse en valores entre 0.50 nudos a 1.50 nudos.

Figura 3.11 Corrientes Superficiales en el Mar Territorial del Estado de Colima (8-13 de Mayo)**.**



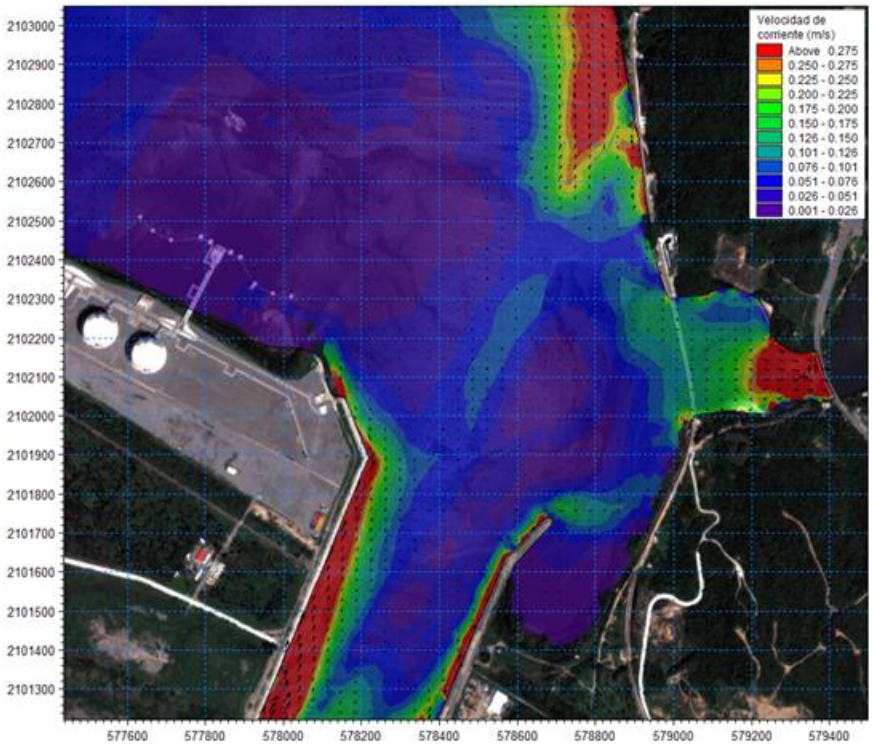
3.6.2 Corriente Interior de la Laguna.

La corriente en el interior de la Laguna contigua a la zona de proyecto se da en la zona de comunicación entre el Vaso II y el Vaso III, en la zona del Puente Malecón de la autopista, la cual se deriva de los efectos de flujo y reflujo de los ciclos de marea. El reflujo es más intenso y de mayor duración que el flujo, mayores velocidades de corriente, durante mareas vivas, mientras que durante mareas muertas es más intenso y de igual o menor duración que el flujo. Lo anterior indica que durante mareas vivas la marea a través del Puente malecón hace la función de exportador neto de aguas y sedimento del Vaso II al Vaso III, mientras que en mareas muertas importa sedimento del Vaso II al Vaso III.

Las corrientes en la zona del NE de la dársena de ciaboga están directamente influenciadas por las corrientes de marea generadas en la sección entre los Vasos II y III, bajo el Puente Malecón (PM), las magnitudes registradas para clima medio superan 0.3 m/s en flujo, y las direcciones predominantes NO es vaciante y ENE en llenante, las corrientes se aceleran entre los Vasos II y III. Dichas corrientes de marea disminuyen al centro de la dársena, mientras que presentan

velocidades de 0.30 m/s a ambos lados de las protecciones marginales, lo que indica un potencial acarreo de sedimento del Canal Tepalcates a la dársena de ciaboga, Figura 3.12.

Figura 3.12 Corrientes Superficiales en el Mar Territorial del Estado de Colima (8-13 de Mayo)**.**

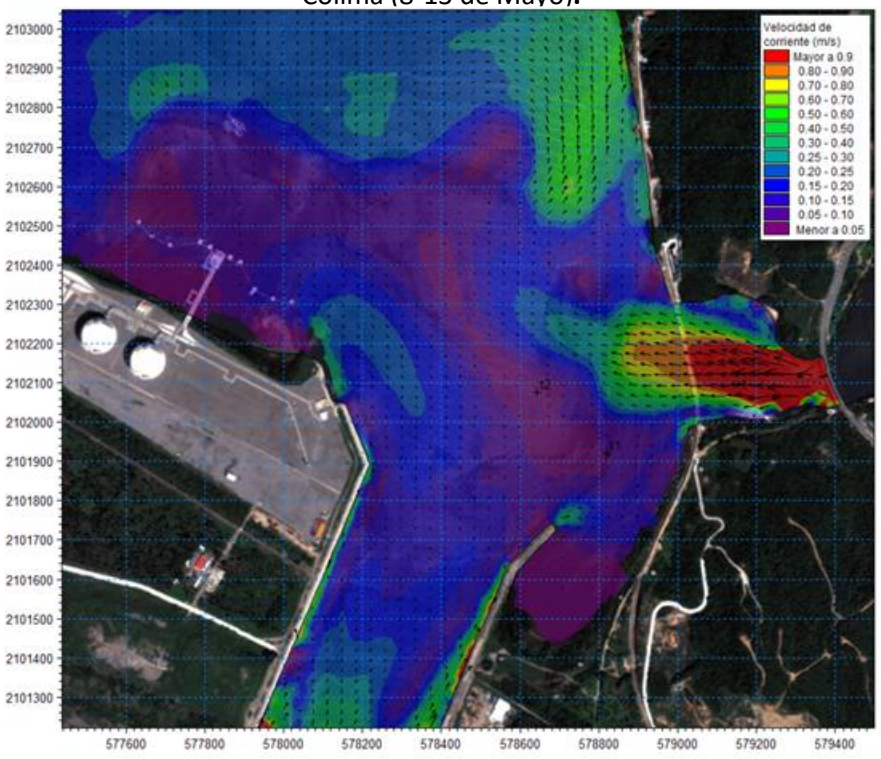


Los gastos aproximados a través de la sección transversal de Puente Malecón alcanzan una magnitud superior a 200 m3/s en mareas vivas, y de 100 m3/s en mareas muertas en el clima medio, mientras que en Puente del ferrocarril disminuyen a 28 m3/s y 14 m3/s, respectivamente. En el Canal Tepalcates la cantidad de agua que entra de manera gruesa es aproximadamente entre 700 m3/s y 1,100 m3/s, en marea vivas y muertas, respectivamente, lo que significa que aproximadamente el 20% del agua que entra por el Canal Tepalcates se dirige a los Vasos III y IV, mientras que el 80% a los Vasos I y II.

Las corrientes que se llegan a generar por efectos de las tormentas en la zona de proyecto alcanzan magnitudes que superan 1.5 m/s en el Puente Malecón, la zona de influencia de las corrientes que cruzan Puente Malecón sobre la dársena llega al centro de la dársena de ciaboga, donde el flujo de agua alcanza velocidades de 0.8 m/s a los 550 m del Puente malecón hacia la

dársena, y 0.30 m /s a los 600 m (cota de -14 m). Dichas corrientes de marea disminuyen al centro de la dársena, mientras que presentan velocidades de 0.15 m/s en el Sur de esta, en el seno de la escollera Este, y centro del Canal Tepalcates. Se muestran también velocidades de 0.40 m/s al oriente de la Terminal de Gas a 350 m al SE del muelle, NE de El Chipote, ver Figura 3.13.

Figura 3.13 Corrientes Superficiales en el Mar Territorial del Estado de Colima (8-13 de Mayo).



3.7 Marea Astronómica.

Uno de los procesos costeros que interviene en la zona lo constituyen las mareas astronómicas, definidas como la variación que experimenta la superficie del mar. Dichas variaciones de nivel diarias observadas en el mar, son debidas principalmente a las fuerzas de atracción de la tierra y la luna, la fuerza centrífuga debida a la órbita de la tierra, el efecto de la fuerza de Coriolis, las fuerzas de fricción del movimiento del agua con el fondo del mar y las fronteras irregulares de la costa sobre la que se desplaza. Debido a las complicaciones asociadas al considerar las fuerzas de carácter general, así como la configuración costera local, la mayoría de la información útil de mareas está basada en mediciones in situ.

Los datos para obtener las características de las mareas fueron obtenidos a partir de las Tablas Numéricas de Predicción de Mareas del 2019, correspondientes al Océano Pacífico, editadas por la Dirección General de Oceanografía Naval de la Secretaría de Marina.

Estas tablas contienen los niveles de pleamares y bajamares diarias, asociadas al tiempo de su ocurrencia para todos los días del año, en diferentes localidades a lo largo de los litorales de nuestro país.

Asimismo, las tablas contienen los niveles de los diferentes planos de mareas, resultado del análisis estadístico y armónico de todos los datos de marea registrados en el pasado en las diversas estaciones contenidas en dichas tablas.

La amplitud de la marea de la zona en estudio fue determinada con base a los planos de marea correspondientes al puerto de Manzanillo, Colima. Los datos de marea se presentan en la Tabla 3.7.

Tabla 3.7 Planos de Marea para Manzanillo.

Planos de Mareas	Elevación	
	[m]	[ft]
Pleamar Máxima Registrada	1.295	4.249
Nivel De Pleamar Media Superior	0.750	2.459
Nivel De Pleamar Media	0.676	2.219
Nivel Medio Del Mar	0.414	1.359
Nivel De Bajamar Media	0.165	0.542
Nivel De Bajamar Media Inferior	0.000	0.000
Bajamar Mínima Inferior	-0.880	-2.887

Fuente: Elaboración propia con base en la información de las Tablas de Predicción de Mareas de la Secretaría de Marina, 2024

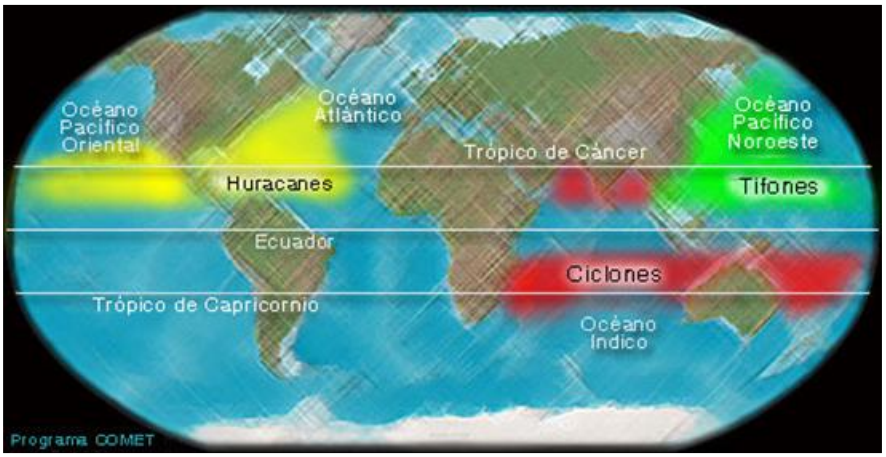
El tipo de marea que se presenta en la zona es mixta semidiurna, ya que de acuerdo con la forma que adopta la curva que representa la variación del nivel del mar, presenta dos pleamares y dos bajamares de diferente magnitud y semidiurna por la ocurrencia de un ciclo completo de marea en un periodo de 12 horas.

3.8 Procesos Físicos Extremos.

3.8.1 Huracanes.

El término "huracán" tiene su origen en el nombre que los indios mayas y caribes daban al dios de las tormentas, pero este mismo fenómeno meteorológico es conocido en la India con el nombre de "ciclón", en las Filipinas se le denomina "baguio", en el oeste del Pacífico norte se le llama "tifón", y en Australia "Willy-Willies", ver Figura 3.14. Estos términos identifican un mismo fenómeno meteorológico.

Figura 3.14 Localización de las Zonas de Huracanes, Ciclones y Tifones**.**



Nota: Mapa del mundo que muestra donde se localizan los huracanes (Océano Atlántico y este del Océano Pacífico), tifones (noroeste del Océano Pacífico) y ciclones (Océanos Índico y Pacífico Sur).

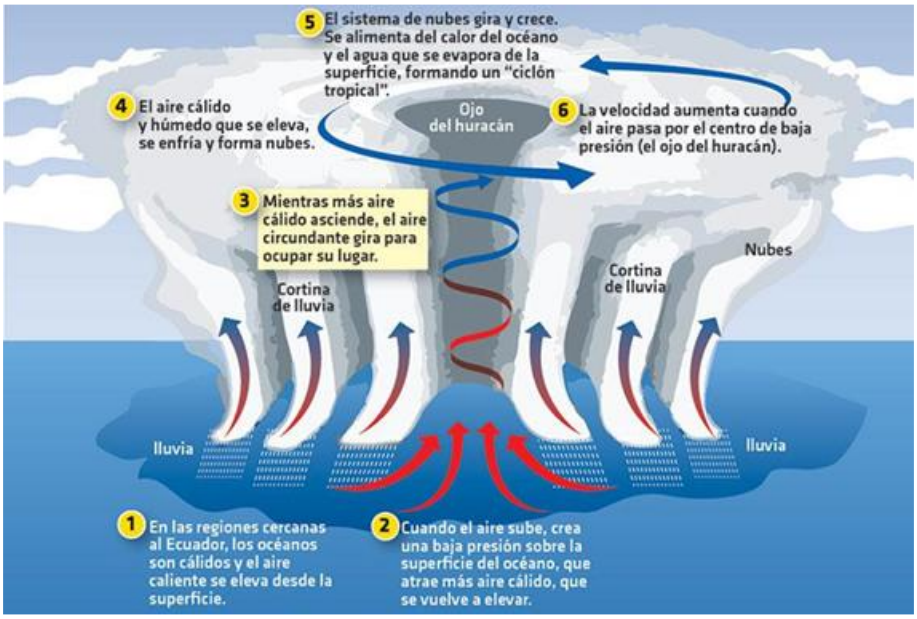
Los huracanes se forman sólo sobre océanos de agua templada, es decir, cerca del ecuador. El aire cálido y húmedo sobre la superficie de los océanos se eleva dejando un área de menor presión cerca del océano. El aire de las áreas circundantes, que tiene mayor presión, gira para llenar el área de baja presión hasta que se vuelve a tornar cálido para seguir elevándose. Cuando se enfría el aire cálido y húmedo que se elevó, se forman nubes. Todo el sistema de nubes y aire gira y va creciendo conforme se alimenta del calor del océano y el agua que se evapora de la superficie. Al girar el sistema de tormenta cada vez más rápido, se forma un ojo en el centro donde todo es tranquilo y claro, con una presión de aire muy baja. Lo anterior se desglosa en una serie de pasos, descritos en la Figura 3.15.

En forma sencilla, un huracán es un viento muy fuerte que se origina en el mar, remolino que se desplaza sobre la superficie terrestre girando en forma de espiral o acarreando humedad en enormes cantidades, y que, al tocar áreas pobladas generalmente causa daños importantes o incluso desastres.

3.8.1.1 Clasificación.

Los huracanes se clasifican en tres tipos de acuerdo con la velocidad de sus vientos máximos, mientras los vientos no rebasen los 63 km/h, se llamará depresión tropical; cuando los vientos tengan una velocidad de entre 63 y 118 km/h se considerará como tormenta tropical, y finalmente cuando rebasen los 118 km/h se convertirá en un huracán.

Figura 3.15 Esquema de Formación de los Huracanes**.**



Existen varias escalas para clasificar los huracanes, en el Pacífico Este y Atlántico se utiliza la escala de Saffir-Simpson (ver Tabla 3.8) para clasificar los huracanes en categorías, según su intensidad de viento.

Tabla 3.8 Escala Saffir - Simpson.

FENÓMENO	VELOCIDAD DE VIENTO [km/h]	MAREA DE TORMENTA [m]	DAÑOS
Depresión Tropical	Menor a 63		Mínimo
Tormenta Tropical	63 - 118		Mínimo
Huracán Categoría 1	119 - 153	1.2 - 1.5	Mínimo
Huracán Categoría 2	154 - 177	1.8 - 2.4	Moderado
Huracán Categoría 3	178 - 209	2.7 - 3.7	Extensivo
Huracán Categoría 4	210 - 249	3.9 - 5.5	Extremo

Huracán Categoría 5	Mayor a 250	Mayor a 5.5	Catastrófico

Por lo general, se debilitan cuando tocan tierra, porque ya no se pueden "alimentar" de la energía proveniente de los océanos templados. Sin embargo, a menudo avanzan bastante tierra adentro causando mucho daño por la lluvia y el viento antes de desaparecer por completo.

En las zonas costeras pueden producir lluvias torrenciales de hasta 9 billones de litros al día, que a su vez pueden ocasionar inundaciones y deslizamientos de tierra. También sobre elevan el nivel del mar con la denominada marea de tormenta, que puede alcanzar los 6 m de altura y se extiende por cientos de kilómetros.

Aunque sus efectos en las poblaciones y embarcaciones pueden ser catastróficos, los huracanes también tienen beneficios ya que transportan el calor de los trópicos a latitudes más templadas, lo que hace que sean un importante mecanismo de la circulación atmosférica global que mantiene en equilibrio la troposfera y mantiene relativamente estable y cálida la temperatura terrestre.

Además, las lluvias que generan pueden traer consigo varios beneficios, como recargar los mantos acuíferos y reducir los efectos de una sequía.

La mejor defensa contra un huracán es un pronóstico exacto que da a la gente tiempo para salir de su camino.

3.8.1.2 Temporada de Huracanes.

Existe un patrón general más o menos constante, pero que puede variar según las condiciones meteorológicas.

A nivel mundial, la actividad ciclónica alcanza su punto máximo al final del verano, cuando la temperatura superficial de los océanos es más cálida. Sin embargo, cada zona en particular tiene diferentes patrones de actividad.

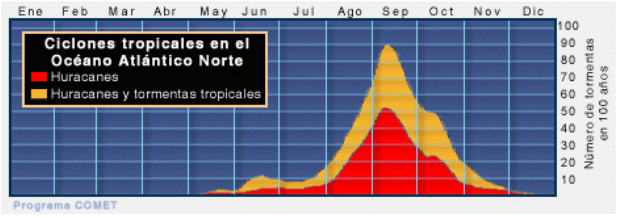
En el Atlántico norte, una temporada de huracanes comienza el día 1 de junio y termina el 30 de noviembre, siendo el mes más activo septiembre. El noreste del Pacífico suele tener un período más largo de actividad, iniciando el 15 de mayo y terminando el 30 de noviembre (ver Figura 3.16).

3.8.1.3 Historia de los Huracanes en la Zona de Estudio

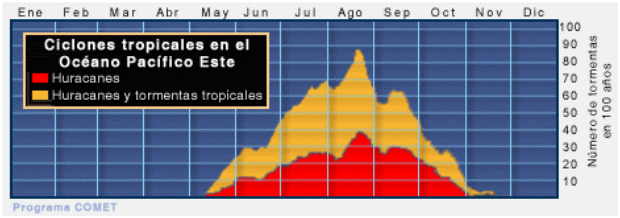
La zona de estudio está expuesta a los huracanes y tormentas tropicales, algunos de ellos peligrosos, basta señalar que a lo largo de la historia se tiene registro de tres huracanes de gran

intensidad, siendo estos el huracán de 1959, huracán Lili de 1971, huracán Eugene de 1987, huracán Calvin 1993 y el huracán Jova del 2011, así como el huracán Olaf en el 2003 (aunque este último toco tierra siendo una tormenta tropical), ver Figura 3.17.

Figura 3.16 Número Promedio de Tormentas Tropicales (amarillo) y Huracanes (rojo) que han Ocurrido en la Cuenca del Atlántico y al Este del Océano Pacífico Durante 100 Años**.**



En el gráfico que muestra el número de tormentas tropicales y huracanes que se producen en el Atlántico Norte en los diferentes meses del año. Hay un pico de actividad a inicios de septiembre, durante un periodo de tiempo que va de junio a finales de noviembre.



En el gráfico se muestra el número de tormentas tropicales y huracanes que ocurren al este del Océano Pacífico durante los diferentes meses del año. El gráfico señala que la temporada de ciclones tropicales va de junio a octubre, con un pico de actividad en agosto.

a) Huracán de 1959.

El huracán México fue un devastador ciclón tropical que afectó la costa del Pacífico mexicano en octubre de 1959, siendo uno de los más fuertes conocidos de la zona del Pacífico Oriental (ver Figura 3.18). Mató a más de 1,000 personas, aunque otras fuentes afirman que llegó a los 1,500 o 1,800, convirtiéndose en uno de los peores huracanes de la década de los cincuenta y el más mortal registrado por un huracán del océano Pacífico.

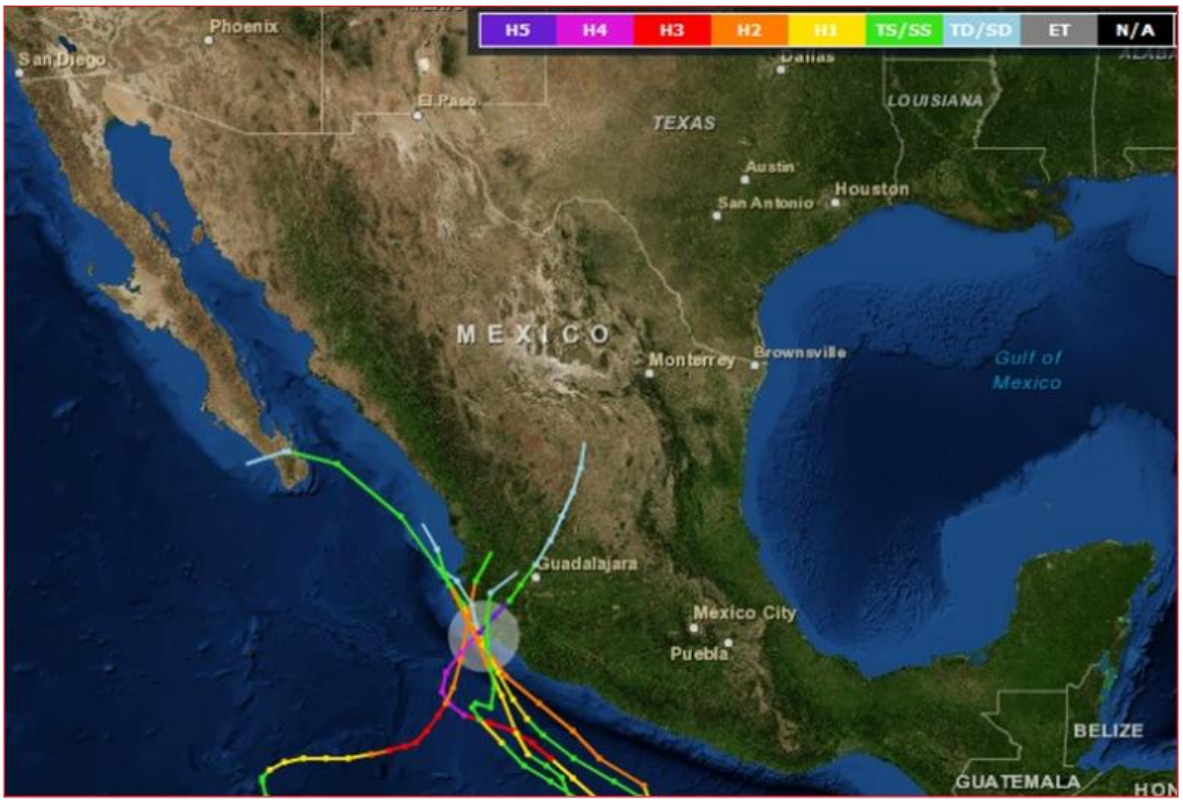
El decimoquinto ciclón tropical conocido en la temporada de 1959 fue observado el 23 de octubre al sur de México. Como ya era un huracán categoría 1, se concluyó que su formación era probablemente de poco antes de esta fecha. Siguió la vía habitual del noroeste de los huracanes en el Pacífico oriental.

El estado de este se intensificó de manera constante, convirtiéndose en un importante huracán el 25 de octubre, alcanzando la categoría 4 en la Escala de Huracanes de Saffir-Simpson al día siguiente. Esto fue seguido por un giro al noreste. Se siguió intensificando, y se convirtió en Categoría 5 el 27 de octubre. Finalmente tocó tierra cerca de Manzanillo, Colima, debilitándose rápidamente por tierra y despareciendo en el centro de México el 29 de octubre.

La presión central más baja que alcanzó fue de 958 hPa. Su máxima de viento fue de 140 nudos (160 mph, 260 km/h). El "best track" indicó que esta velocidad se logró después de tocar tierra. Sin embargo, una revisión menor corrige este error, dejando claro que el huracán fue reforzado por el agua y confirmó que el huracán llegó a tierra con fuertes vientos según un documento que marca el dato por encima de los 135 nudos (155 mph) en Manzanillo. La revisión

también indicó que el huracán pudo haber tenido vientos más altos que los registrados oficialmente.

Figura 3.17 Trayectoria de las Tormentas que han Tocado Tierra Cercana a la Zona de Estudio**.**



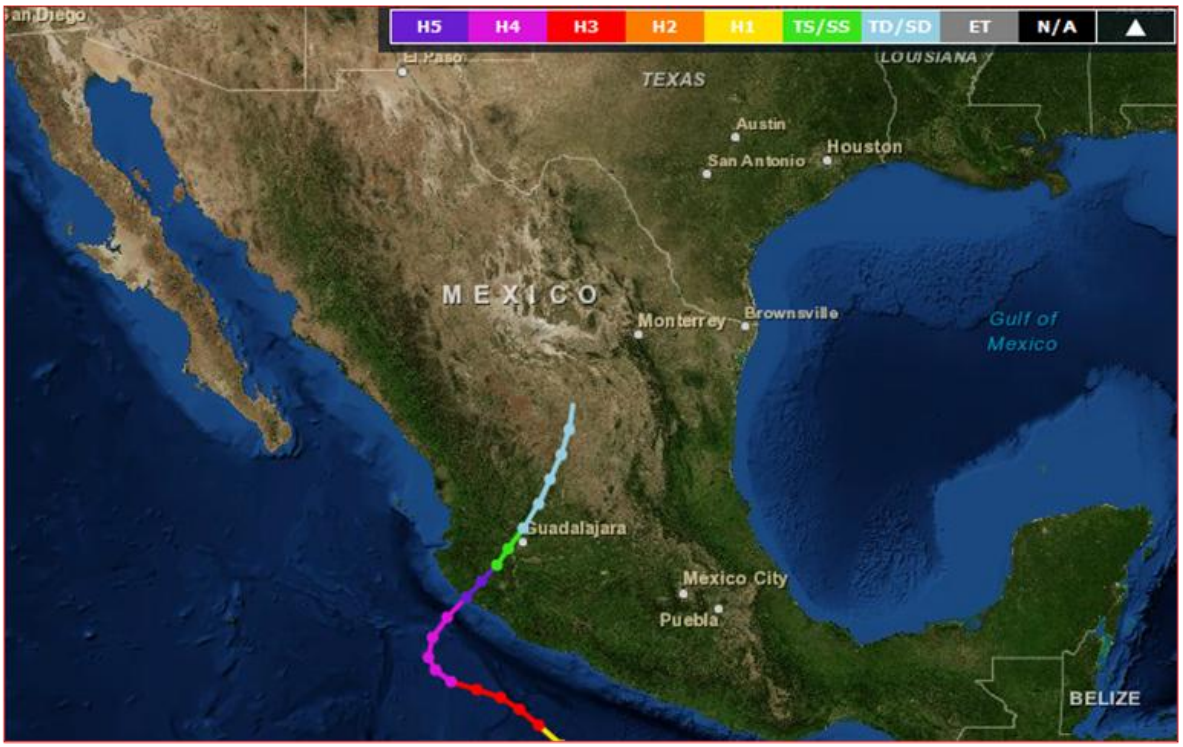
Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

b) Huracán Lily de 1971.

El huracán Lily fue un huracán de categoría 1, que devastó la ciudad de Puerto Vallarta. La formación de un área de nubosidad asociada a una tormenta tropical, que se intensificó lentamente hasta convertirse en un huracán categoría 1, presentando su mayor intensidad justo antes de tocar tierra al noroeste de Manzanillo, Colima el 31 de agosto, ver Figura 3.19.

El huracán se debilitó rápidamente y se convirtió en una depresión tropical. Después de salir de la tierra, los restos de la tormenta Lily se disipan el 1 de septiembre. El movimiento de la tormenta cerca de la costa presentó un número elevado de afectados debido a una advertencia limitada, debido parcialmente a las dificultades que se tuvo para identificar la posición del huracán en el radar de los aviones de reconocimiento.

Figura 3.18 Trayectoria de las Tormentas que han Tocado Tierra Cercana a la Zona de Estudio**.**



Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

Este había sido el peor huracán que ha tocado tierra en la zona de Puerto Vallarta en dos décadas y el segundo huracán de la temporada en impactar fuertemente las costas mexicanas tras el paso del huracán Bridget.

La tormenta causó el desbordamiento del río Cuale, inundando la sección del centro de Puerto Vallarta con una altura de agua de 2.40 m. Dado que los caminos fueron inundados o bloqueados con derrumbes, el ejército mexicano prestó ayuda vía aérea.

El huracán también pasó por la localidad de Barra de Navidad, donde existe una leyenda local, los residentes cuentan que durante el huracán Lily llegó a las costas de Jalisco afectando a las comunidades costeras de la región, principalmente Barra de Navidad, sus habitantes se refugiaron en la iglesia de la comunidad por ser la construcción más sólida. Y la historia cuenta que durante la tormenta uno de los brazos de la imagen en el altar se trozo parcialmente y cayó a un costado, enseguida sucedió lo mismo con el otro brazo; así cuando el Cristo bajo los brazos de la

cruz de donde los tenía clavados, la tormenta cesó y el fuerte viento bajo su intensidad. El resto del cuerpo del Cristo no sufrió ningún otro daño. Actualmente los brazos continúan colgados, de la misma manera como continúa el agradecimiento de la población por el milagro y la imagen se conoce como el Cristo del ciclón o Cristo de los brazos caídos.

Figura 3.19 Trayectoria del Huracán Lily de 1971**.**

Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

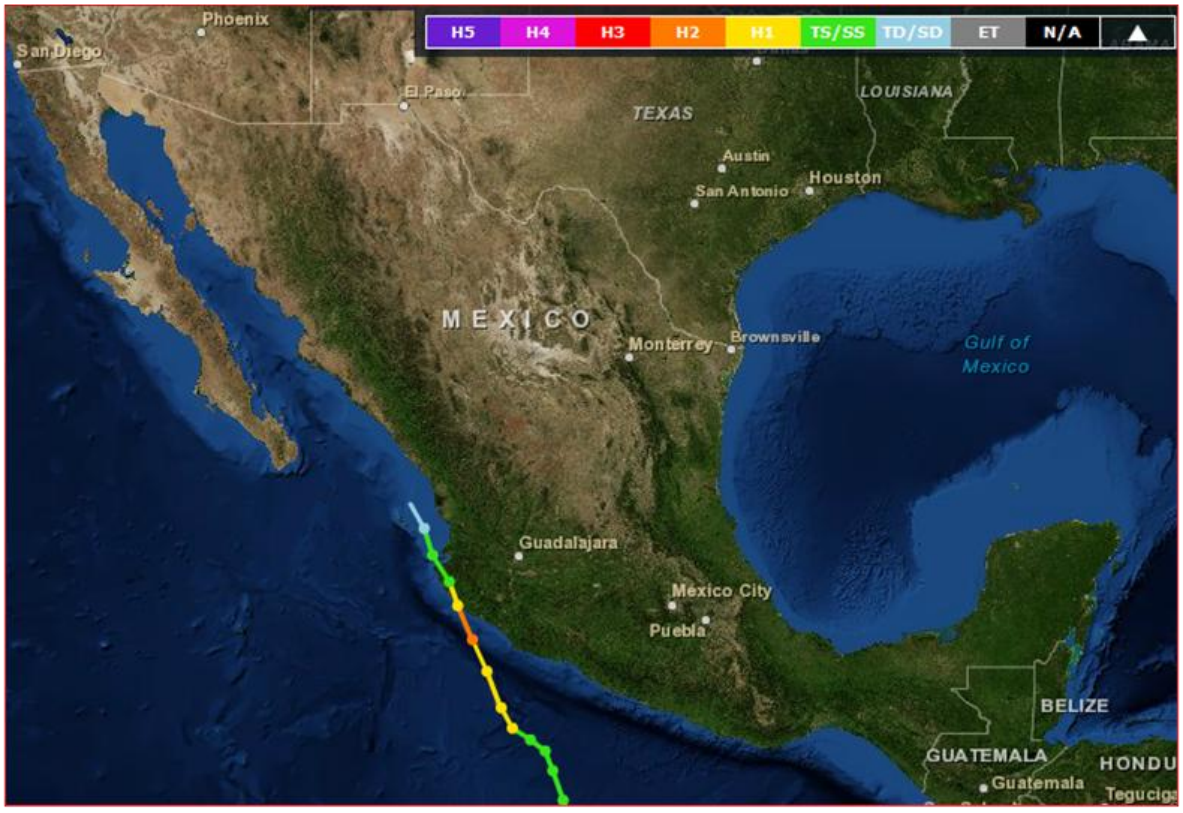
El huracán se llevó tres vidas en el continente y nueve vidas cuando un barco se hundió.

c) Huracán Eugene de 1987.

El huracán Eugene fue el único ciclón tropical que tocó tierra en México durante la temporada de huracanes del Pacífico de 1987. Eugene fue octavo ciclón tropical, la quinta tormenta con nombre, y el primer huracán de la temporada.

Eugene se desarrolló el 22 de julio a partir de una perturbación tropical localizada lejos de costas de México. Más tarde ese mismo día, el sistema se intensificó a tormenta tropical mientras se movía hacia el noroeste. Eugene alcanzó la categoría de huracán el 24 de julio, y fue clasificado brevemente como un huracán de categoría 2, dos días después, ver Figura 3.20.

Figura 3.20 Trayectoria del Huracán Eugene de 1987**.**



Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

Posteriormente el huracán Eugene se debilitó a un huracán de categoría 1, una vez que tocó tierra cerca de las costas de Barra de Navidad. Poco después de tocar tierra, Eugene se debilitó rápidamente, pasando a ser una tormenta tropical, y cuando volvió a surgir en aguas abiertas se disipó rápidamente.

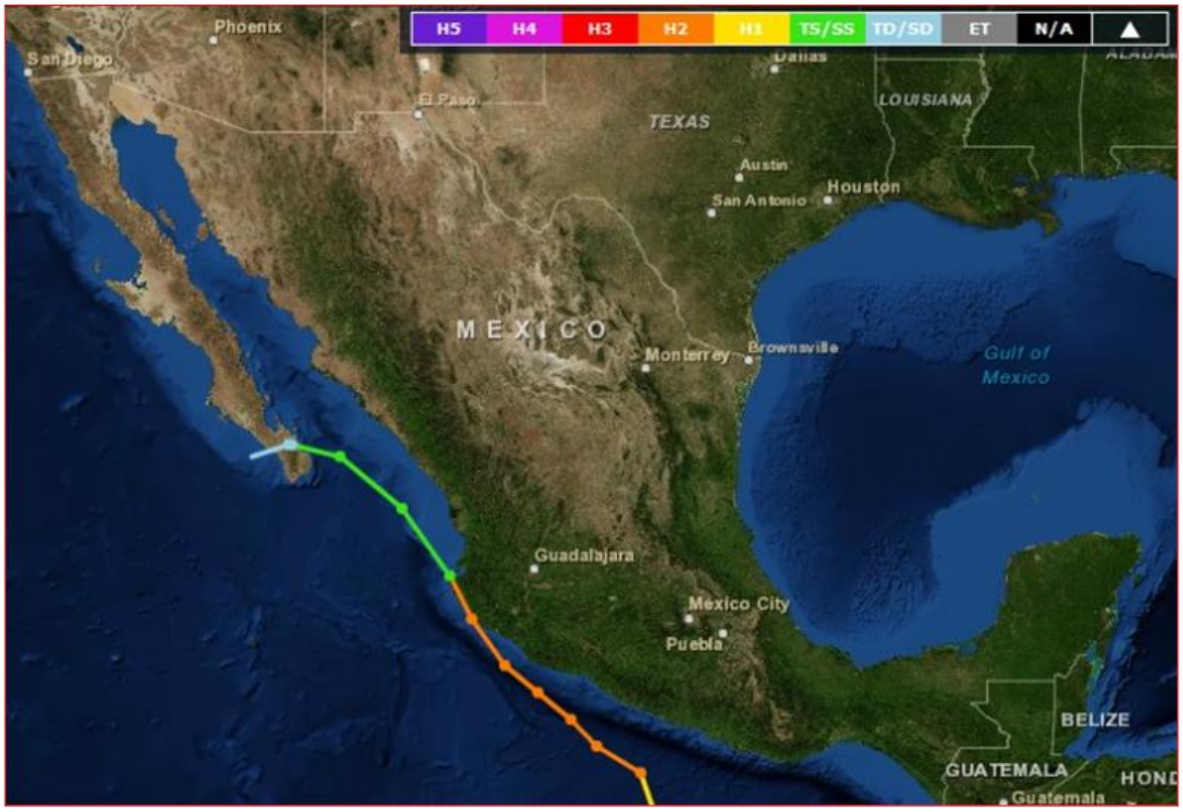
A lo largo de México, la tormenta produjo fuertes vientos, especialmente en la parte suroeste del país. El huracán inundó la costa suroeste de México, dando lugar a las lluvias más intensas en cinco estados mexicanos asociadas a un huracán. Más de 5,000 personas se quedaron sin hogar. El aeropuerto de Manzanillo fue cerrado por los daños que sufrió la torre de control. Por

otra parte, entre 200 y 300 casas fueron destruidas en Colima. En total, Eugene lesionó a 18 personas y causó tres muertes y dejo daños estimados en $142,120,000 de dólares (costos estimados en 1987).

d) Huracán Calvin de 1993.

El huracán Calvin fue uno de los huracanes que se registraron en el océano Pacífico y que tocaron tierra en costas mexicanas durante el mes de julio. Fue el cuarto ciclón tropical, la tercera tormenta con nombre y segundo huracán de la temporada de huracanes del Pacífico de 1993, ver Figura 3.21.

Figura 3.21 Trayectoria del Huracán Eugene de 1987**.**

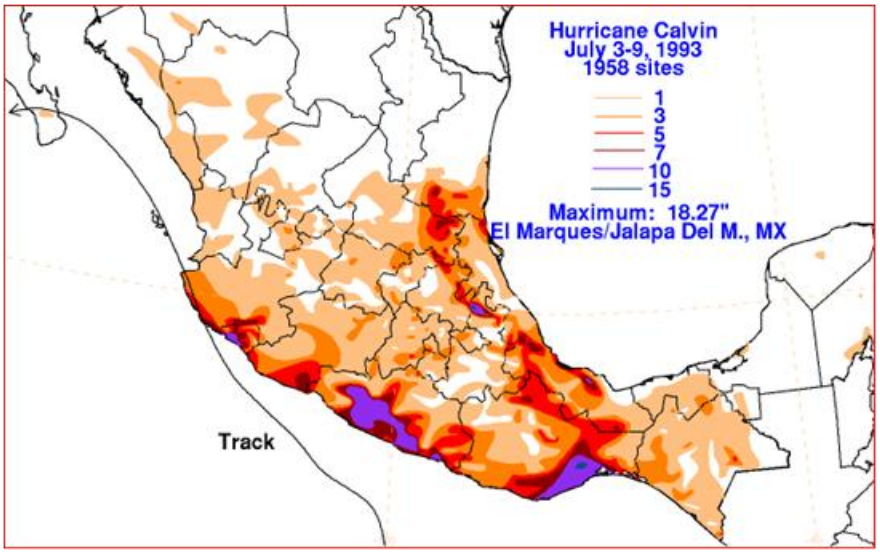


Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

Cuando Calvin volvió a tocar tierra mexicana, cerca de la punta sur de la Península de Baja California la noche del 08 de julio, se debilitó a depresión tropical y para la mañana del día 9 de julio, la depresión se disipó poco después de entrar en el Océano Pacífico por tercera vez.

Por su paso a lo largo de las costas de México, Calvin dejó fuertes lluvias, sobre todo en la parte suroeste del país (ver Figura 3.22). Las fuertes lluvias produjeron inundaciones, que, a su vez, causaron deslizamientos de tierra en varios estados.

Figura 3.22 Intensidad de Lluvia por el Huracán Calvin de 1993**.**



Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

Calvin se desarrolló el 4 de julio a partir de un área de convección en el sur de México. Al día siguiente, el sistema se intensificó en una tormenta tropical, que fue nombrado Calvin. La tormenta continúo fortaleciéndose y pasó a ser un huracán el 06 de julio, clasificándose como un huracán de categoría 2 en la escala Saffir-Simpson.

Para el 07 de julio, el huracán Calvin tocó tierra cerca de las costas de Barra de Navidad con su fuerza máxima. Sin embargo, Calvin se debilitó rápidamente tras tocar tierra, y cuando reapareció en el Océano Pacífico sobre la primera el 8 de julio ya era una tormenta tropical. El huracán siguió debilitándose mientras se dirigía rápidamente hacia el noroeste.

A raíz de Calvin, se reportaron 37 muertes. La mayoría de las muertes se debieron a inundaciones o accidentes automovilísticos. En el estado de Michoacán, se destruyeron 700 hogares. Además, se informó de marejada de 4.6 m. Muchos barcos y las estructuras de la costa de Acapulco a Barra de Navidad fueron dañados. La marejada cerca de Lázaro Cárdenas en el oeste de México causó una fuga de un barco que contenía ácido sulfúrico.

Las actividades de limpieza se llevaron a cabo en un mes. En total, 30,000 personas fueron desplazadas por la tormenta y el monto de los daños ascendió a $32 millones dólares (costos de 1993).

e) Huracán Jova del 2011.

El día 5 de octubre por la noche se formó la depresión tropical No. 10-E de la temporada 2011 en el Pacífico Nororiental, la cual se inició a partir de una baja presión originada dentro de la vaguada monzónica al Sur del estado de Guerrero, donde se dieron las condiciones favorables que permitieron la formación de la DT-10 a 1,005 km al Sur de Manzanillo, Col. con vientos máximos sostenidos de 55 km/h, rachas de 75 km/h y desplazamiento hacia el Oeste a 15 km/h, ver Figura 3.23.

Figura 3.23 Trayectoria del Huracán Jova del 2011**.**

Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

La depresión tropical No. 10 continuó su desplazamiento hacia el Noroeste y el día 6 por la tarde, se ubicó a una distancia de 800 km al Sursuroeste de Manzanillo, Col., con vientos máximos sostenidos de 65 km/h y rachas de 85 km/h, es decir, fuerza de tormenta tropical, por lo que se le asignó el nombre de “Jova”.

La tormenta tropical “Jova” seguía ganando fuerza mientras cambiaba gradualmente el rumbo de su trayectoria. El día 7 de octubre por la tarde se ubicó a 815 km al Suroeste de Manzanillo, Col., con vientos máximos sostenidos de 100 km/h, rachas de 120 km/h y desplazamiento hacia el Nor-Noroeste a 13 km/h.

El día 8 por la tarde, se ubicó a 710 km al Oeste-Suroeste de Manzanillo, Col., ya como huracán, con vientos máximos sostenidos de 120 km/h, rachas de 150 km/h y desplazamiento hacia el Este-Noreste a 6 km/h.

Mientras avanzaba hacia el Este el huracán “Jova” siguió ganando fuerza y mayor velocidad en su desplazamiento y así, el día 9 de octubre por la noche, se encontraba a 420 km al Suroeste de Manzanillo, Col. con vientos máximos sostenidos de 160 km/h y rachas de 195 km/h como huracán de categoría II y en la madrugada del día 10, alcanzó la categoría III, con vientos máximos sostenidos de 195 km/h y rachas de 240 km/h cuando se encontraba a 430 km al Suroeste de Manzanillo, Col.

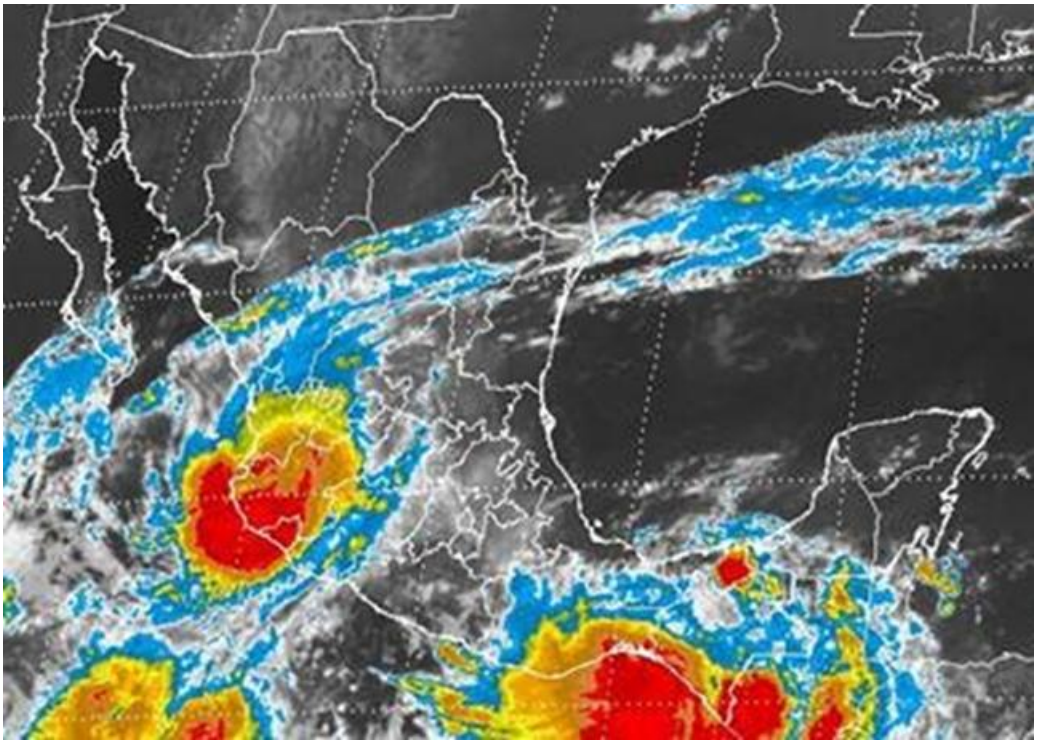
El día 10 de octubre por la mañana, “Jova” alcanzó su mayor intensidad con vientos máximos sostenidos de 205 km/h y rachas de 250 km/h dentro de la categoría III de la escala Saffir-Simpson, a 400 km al Suroeste de Manzanillo, Col., misma fuerza que mantuvo hasta el anochecer de este día, cuando empezó a debilitarse como resultado del contacto de sus bandas nubosas con la costa occidental de México, pero manteniéndose dentro de la categoría III, con vientos máximos sostenidos de 195 km/h y rachas de 240 km/h, a una distancia de 255 km al Suroeste de Manzanillo, Col.

Mientras se desplazaba lentamente hacia el Nor-Noreste acercándose a la costa de Jalisco, “Jova” siguió perdiendo fuerza, por lo que el día 11 poco después del mediodía, se debilitó a huracán de categoría II, con vientos máximos sostenidos de 160 km/h y rachas de 195 km/h a una distancia de 175 km al Suroeste de Manzanillo, Col., fuerza con la que se mantuvo hasta las 01:00 horas local del día 12, cuando el centro del sistema se encontraba en la línea de costa, a 8 km al Sur de La Fortuna, Jal., pues a partir de ese momento, debido a la fricción con el terreno, “Jova” siguió debilitándose rápidamente, por lo que a las 4:00 horas, ya se encontraba en tierra, en las cercanías de la población de Puentecillas, del municipio de Tomatlán, Jal., con vientos máximos sostenidos de 140 km/h, rachas de 165 km/h y desplazamiento hacia el Norte a 15 km/h, ver Figura 3.24.

Mientras avanzaba hacia el Norte sobre territorio del Occidente del estado de Jalisco, “Jova” siguió debilitándose por lo que a las 10:00 horas del día 12, cuando se encontraba a 16 km

al Oeste-Noroeste de la población de Atajo, Jal., se degradó a tormenta tropical con vientos máximos sostenidos de 100 km/h y rachas de 130 km/h.

Figura 3.24 Imagen Satelital del Huracán Jova del 2011**.**



Fuente: CONAGUA, 2019.

La tormenta tropical “Jova” continuó su trayectoria hacia el Norte sobre el Occidente del país, debilitándose rápidamente por el efecto de fricción sobre el terreno y así, por la tarde del día 12, se degradó a depresión tropical presentando vientos máximos sostenidos de 55 km/h y rachas de 75 km/h a una distancia de 35 km al Este-Sureste de Tepic, Nay.

Finalmente, a las 22:00 horas del día 12, la depresión tropical “Jova” se ubicó a 75 km al Este-Noreste de Tepic, Nay., con vientos máximos sostenidos de 45 km/h y rachas de 65 km/h, muy próxima a debilitarse a una baja presión remanente.

Jova dejó un saldo de nueve personas muertas y seis personas resultaron heridas. En el estado de Jalisco, el huracán provocó un deslizamiento de tierra en el municipio de Cihuatlán, asimismo, varias carreteras fueron dañadas por la tormenta.

A lo largo del estado de Jalisco, las pérdidas por Jova sumaron 1.3 mil millones de pesos ($ 96,1 millones dólares EE. UU.) y aproximadamente 46.280 personas se vieron afectadas. En Colima, las pérdidas preliminares para la industria del turismo se estimaron en 170 millones de pesos (12.700.000 dólares USD), los daños a la infraestructura de Colima alcanzaron 1,283 millones de pesos (94.870.000 dólares USD).

f) Huracán Olaf del 2003.

El día 3 de octubre del año 2003, por la mañana, se formó la depresión tropical No. 15-E de la temporada en el Océano Pacífico Nororiental; se inició a 500 km al Sursuroeste de Puerto Escondido, Oax., con vientos máximos sostenidos de 55 km/h, rachas de 75 km/h y presión mínima de 1005 hPa. Mientras se desplazaba hacia el Noroeste en forma paralela a las costas nacionales, la DT-15 adquiría mayor fuerza, por lo que, en la tarde de este día, cuando se encontraba a 446 km al Suroeste de Puerto Escondido, Oax., se desarrolló a la tormenta tropical “Olaf” con vientos máximos sostenidos de 75 km/h y rachas de 95 km/h, alcanzando al final del día, vientos máximos sostenidos de 85 km/h con rachas de 100 km/h, ver Figura 3.25.

Figura 3.25 Trayectoria del Huracán Olaf del 2003**.**

Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

Durante el día 4, “Olaf” siguió su trayectoria con desplazamiento predominante hacia el Noroeste, mientras seguía intensificándose, por lo que al final de este día, cuando se encontraba a 280 km al Suroeste de Lázaro Cárdenas, Mich., ya tenía vientos máximos sostenidos de 110 km/h con rachas de 140 km/h.

El día 5 por la mañana, cuando se encontraba a 215 km al Sur de Manzanillo, Col., con rumbo hacia el Noroeste, “Olaf” se intensificó a huracán alcanzando vientos máximos sostenidos de 120 km/h con rachas de 150 km/h, misma fuerza con la que se mantuvo durante el resto de este día.

Aunque se había mantenido muy cerca del litoral central del Pacífico mexicano, fue hasta el día 6 por la mañana, cuando con el empleo de las imágenes del radar meteorológico de Cuyutlán, Colima, se detectó que “Olaf” adoptaba un desplazamiento franco con rumbo hacia el Norte debido a que se ubicaba en el borde Suroeste de una cuña de alta presión en la corriente de arrastre en la capa media de 850-250 hPa, convirtiéndose en una seria amenaza para las costas de Jalisco y Colima. La cercanía a la costa y la rotación del sistema, golpeando con sus bandas nubosas sobre el litoral central del Pacífico, originó su pérdida de fuerza y así, poco después del mediodía, cuando se encontraba a 140 km al Sur de Manzanillo, Col., el huracán “Olaf” se debilitó a tormenta tropical, con vientos máximos sostenidos de 65 km/h y rachas de 85 km/h. Durante el resto del día “Olaf” estuvo recuperando fuerza mientras se acercaba lentamente a las costas de Colima y Jalisco, por lo que al final del día, a una distancia de 35 km al Sursuroeste de Manzanillo, Col., presentó vientos máximos sostenidos de 95 km/h con rachas de 110 km/h.

En las primeras horas del día 7, el centro de la tormenta tropical “Olaf” se localizó a 30 km al Oeste de Manzanillo, Col., y a 25 km al Sur de Cihuatlán, Jal., con vientos máximos sostenidos de 100 km/h y rachas de 120 km/h, misma fuerza con la que poco después, alrededor de las 2:00 de la mañana, hora local, la tormenta tropical “Olaf” tocó tierra en los límites entre Colima y Jalisco, a 8 km al Sursuroeste de Cihuatlán, Jal. A las 4:00 horas locales, “Olaf” se localizó en tierra, 10 km al Norte de Cihuatlán, Jal., con vientos máximos sostenidos de 95 km/h con rachas de 110 km/h.

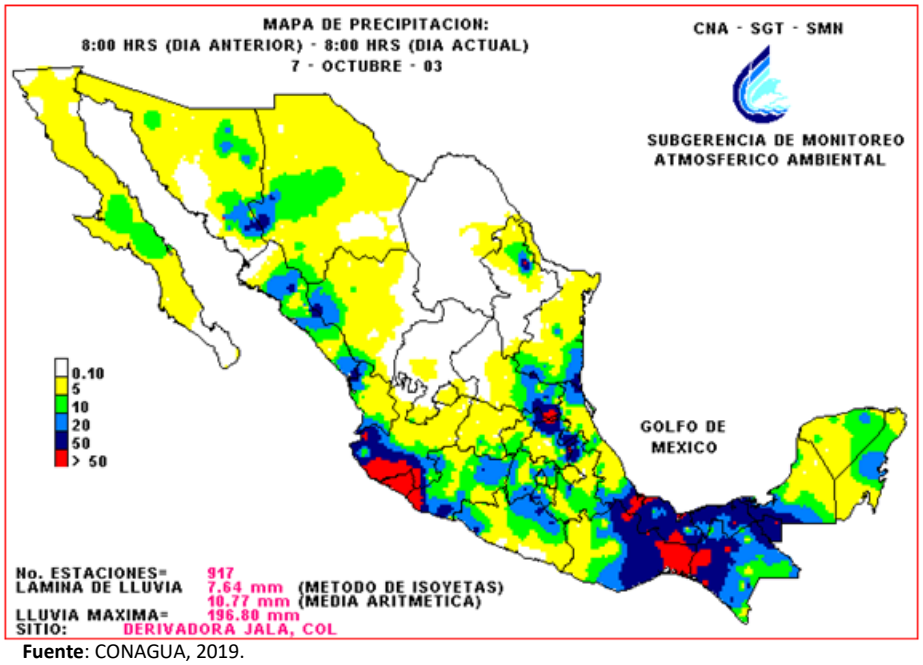
“Olaf” siguió su trayecto sobre el Occidente del estado de Jalisco, mientras se debilitaba rápidamente al encontrarse con la Sierra de Cacoma y así, poco después del mediodía, cuando se encontraba a unos 100 km al Este-Sureste de Puerto Vallarta, Jal., se degradó a depresión tropical con vientos máximos sostenidos de 55 km/h y rachas de 75 km/h. Por la tarde del día 7, la depresión tropical “Olaf” pasó a unos 85 km al Este de Puerto Vallarta, y a 40 km al Oeste de Ameca, Jal., con vientos máximos sostenidos de 45 km/h y rachas de 65 km/h, misma fuerza con la que entró a territorio de Nayarit en las primeras horas de la noche, localizándose a 80 km al Sursureste de Tepic, Nay., y a 15 km al Suroeste de Ixtlán del Río, Nay.

Finalmente, después de mantenerse con desplazamiento hacia el Norte por varias horas, al final del día 7, “Olaf” entró nuevamente a territorio de Jalisco, esta vez, por la parte que se

extiende hacia el Norte, localizándose a 30 km al Norte de Tequila, Jal., con vientos máximos sostenidos de 45 km/h y rachas de 65 km/h, ya en proceso de disipación.

Los registros de lluvia máxima puntual en 24 horas, originados durante el recorrido de "Olaf" fueron de 196.8 mm en Derivadora Jala, Col. y 87.0 mm en Cihuatlán, Jal., el día 6 de octubre, y de 87.0 mm en Gaviotas, Nay., 72.2 mm en Colima, Col., y 71.0 mm en Basilio Badillo, Jal., el día 7 del mismo mes (ver Figura 3.26).

Figura 3.26 Mapa de Lluvia Acumulada del Día 6 al 7 de Octubre del 2003**.**



Fuente: CONAGUA, 2019.

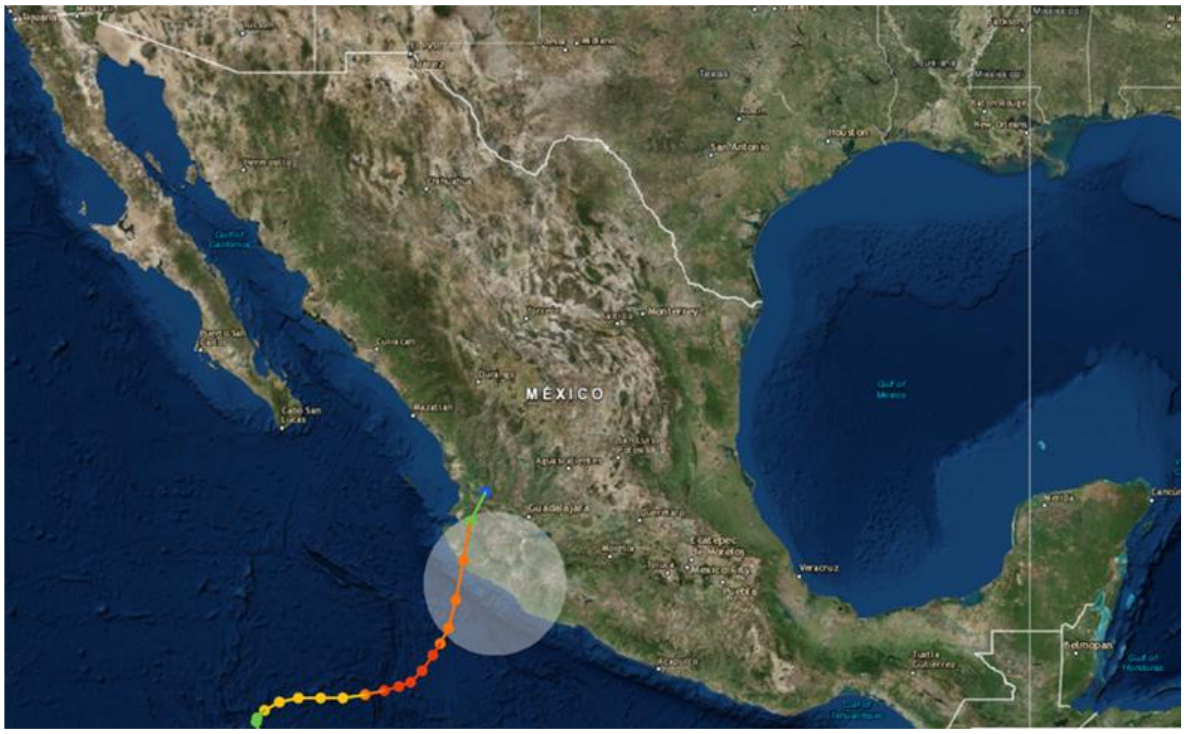
El huracán "Olaf" afectó varios estados de la costa Sur y Occidente del país, aunque los efectos más importantes se dieron en Colima y Jalisco, en donde dio lugar a inundaciones con importantes daños materiales en viviendas, carreteras, zonas agrícolas y servicios de energía eléctrica y telefonía, entre otros.

El desarrollo de las diferentes etapas del ciclón "Olaf" tuvo una duración de 108 horas, tiempo en el que recorrió un total de 1,975 km, a una velocidad promedio de 18 km/h.

g) Huracán Jova de 2011

El día 5 de octubre por la noche se formó la depresión tropical No. 10-E de la temporada 2011 en el Pacífico Nororiental, la cual se inició a partir de una baja presión originada dentro de la vaguada monzónica al Sur del estado de Guerrero, donde se dieron las condiciones favorables que permitieron la formación de la DT-10 a 1,005 km al Sur de Manzanillo, Col. con vientos máximos sostenidos de 55 km/h, rachas de 75 km/h y desplazamiento hacia el Oeste a 15 km/h, ver Figura 3.27.

Figura 3.27 Trayectoria del Huracán Jova del 2011**.**



Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

La depresión tropical No. 10 continuó su desplazamiento hacia el Noroeste y el día 6 por la tarde, se ubicó a una distancia de 800 km al Sur-Suroeste de Manzanillo, Colima, con vientos máximos sostenidos de 65 km/h y rachas de 85 km/h, es decir, fuerza de tormenta tropical, por lo que se le asignó el nombre de “Jova”.

La tormenta tropical “Jova” seguía ganando fuerza mientras cambiaba gradualmente el rumbo de su trayectoria. El día 7 de octubre por la tarde se ubicó a 815 km al Suroeste de

Manzanillo, Colima, con vientos máximos sostenidos de 100 km/h, rachas de 120 km/h y desplazamiento hacia el Nor-Noroeste a 13 km/h.

El día 8 por la tarde, se ubicó a 710 km al Oeste-Suroeste de Manzanillo, Colima, ya como huracán, con vientos máximos sostenidos de 120 km/h, rachas de 150 km/h y desplazamiento hacia el Este-Noreste a 6 km/h.

Mientras avanzaba hacia el Este el huracán “Jova” siguió ganando fuerza y mayor velocidad en su desplazamiento y así, el día 9 de octubre por la noche, se encontraba a 420 km al Suroeste de Manzanillo, Col. con vientos máximos sostenidos de 160 km/h y rachas de 195 km/h como huracán de categoría II y en la madrugada del día 10, alcanzó la categoría III, con vientos máximos sostenidos de 195 km/h y rachas de 240 km/h cuando se encontraba a 430 km al Suroeste de Manzanillo, Colima.

El día 10 de octubre por la mañana, “Jova” alcanzó su mayor intensidad con vientos máximos sostenidos de 205 km/h y rachas de 250 km/h dentro de la categoría III de la escala Saffir-Simpson, a 400 km al Suroeste de Manzanillo, Colima, misma fuerza que mantuvo hasta el anochecer de este día, cuando empezó a debilitarse como resultado del contacto de sus bandas nubosas con la costa occidental de México, pero manteniéndose dentro de la categoría III, con vientos máximos sostenidos de 195 km/h y rachas de 240 km/h, a una distancia de 255 km al Suroeste de Manzanillo, Colima.

Mientras se desplazaba lentamente hacia el Nor-Noreste acercándose a la costa de Jalisco, “Jova” siguió perdiendo fuerza, por lo que el día 11 poco después del mediodía, se debilitó a huracán de categoría II, con vientos máximos sostenidos de 160 km/h y rachas de 195 km/h a una distancia de 175 km al Suroeste de Manzanillo, Colima, fuerza con la que se mantuvo hasta las 01:00 horas local del día 12, cuando el centro del sistema se encontraba en la línea de costa, a 8 km al Sur de La Fortuna, Jalisco, pues a partir de ese momento, debido a la fricción con el terreno, “Jova” siguió debilitándose rápidamente, por lo que a las 4:00 horas, ya se encontraba en tierra, en las cercanías de la población de Puentecillas, del municipio de Tomatlán, Jalisco, con vientos máximos sostenidos de 140 km/h, rachas de 165 km/h y desplazamiento hacia el Norte a 15 km/h.

Mientras avanzaba hacia el Norte sobre territorio del Occidente del estado de Jalisco, “Jova” siguió debilitándose por lo que a las 10:00 horas del día 12, cuando se encontraba a 16 km al Oeste-Noroeste de la población de Atajo, Jal., se degradó a tormenta tropical con vientos máximos sostenidos de 100 km/h y rachas de 130 km/h.

La tormenta tropical “Jova” continuó su trayectoria hacia el Norte sobre el Occidente del país, debilitándose rápidamente por el efecto de fricción sobre el terreno y así, por la tarde del día 12, se degradó a depresión tropical presentando vientos máximos sostenidos de 55 km/h y rachas de 75 km/h a una distancia de 35 km al Este-Sureste de Tepic, Nayarit.

Finalmente, a las 22:00 horas del día 12, la depresión tropical “Jova” se ubicó a 75 km al Este-Noreste de Tepic, Nayarit, con vientos máximos sostenidos de 45 km/h y rachas de 65 km/h, muy próxima a debilitarse a una baja presión remanente.

Jova dejó un saldo de nueve personas muertas y seis personas resultaron heridas. En el estado de Jalisco, el huracán provocó un deslizamiento de tierra en el municipio de Cihuatlán, asimismo, varias carreteras fueron dañadas por la tormenta.

A lo largo del estado de Jalisco, las pérdidas por Jova sumaron 1.3 mil millones de pesos y aproximadamente 46,280 personas se vieron afectadas. En Colima, las pérdidas preliminares para la industria del turismo se estimaron en 170 millones de pesos, mientras que los daños a la infraestructura alcanzaron 1,283 millones de pesos.

h) Huracán Patricia del 2015

El seguimiento de este sistema inició el 17 de octubre al observarse un centro de baja presión de 1006 milibares, localizado al Sursureste del Golfo de Tehuantepec, a 240 km de Puerto Chiapas. Fue desplazándose al Oeste con una velocidad de 4 m/s y vientos máximos sostenidos de 56 km/h. La noche del 20 de octubre se convirtió en Tormenta Tropical y recibió el nombre de Patricia.

A pesar de su rápida intensificación, la tormenta se desplazaba lentamente. El día 22 de octubre a primera hora, Patricia se convirtió en huracán de categoría 1, a 363 km al Sursuroeste de Acapulco, con una presión mínima de 987 milibares y vientos sostenidos de 120 km/h. Por su proximidad a la costa, sus bandas nubosas afectaron la región occidental de Jalisco, Colima, Michoacán, Guerrero y Oaxaca (ver Figura 3.28).

A lo largo de ese mismo día, 22 de octubre, patricia pasó de categoría 1 a 4, y las primeras horas del 23 de octubre por fin alcanzó la máxima categoría de la escala Saffir-Simpson, la categoría 5; situado a 330 km al Sur de Manzanillo.

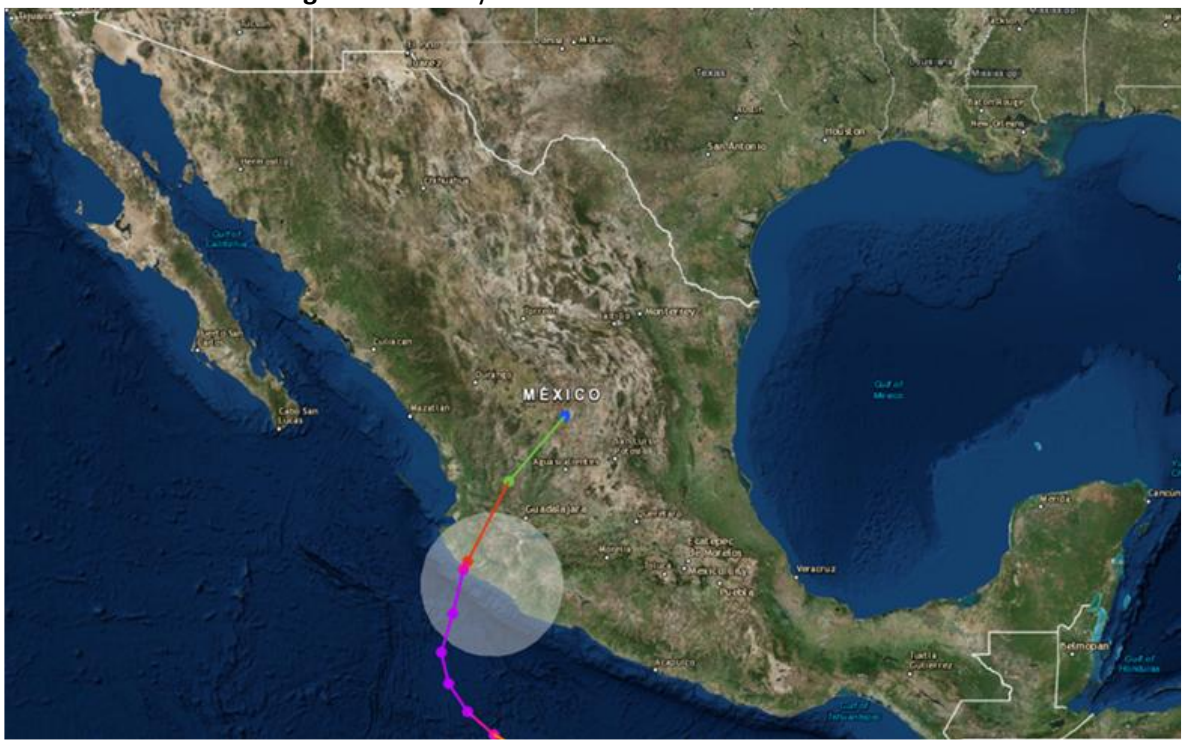
Fue hasta las primeras horas del 24 de octubre que Patricia se observó sobre tierra, a 75 km al Este de Puerto Vallarta, Jalisco, mientras mantenía la categoría 4. En las inmediaciones de bahía Chamela se fue debilitando hasta que bajó a categoría 1.

Avanzó tierra adentro, degradándose cada vez más, y pasó por los estados de Jalisco, Nayarit, Zacatecas y Nuevo León, hasta disiparse totalmente la noche del 24 de octubre.

Si bien el huracán Patricia fue catalogado por la Comisión Nacional del Agua y el Centro Nacional de Huracanes como el “más poderoso que haya existido en el planeta en toda la historia”, afortunadamente para la población no causó daños tan graves como se hubieran esperado. Esto gracias a varios factores, entre ellos destacan que la ruta de Patricia fue por zonas

montañosas (Sierra Madre Occidental y Sierra Volcánica Transversal), escasamente pobladas y alejadas de las grandes ciudades, lo cual dificultó su circulación mientras se iba disipando; además, las bandas de viento del huracán Patricia eran muy angostas.

Figura 3.28 Trayectoria del Huracán Patricia del 2015**.**



Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

No se reportaron pérdidas humanas, lo cual refleja un buen manejo de medidas de seguridad por parte de las autoridades. En cuanto a la infraestructura, se reportaron en Colima muchas afectaciones a las vialidades, daños a viviendas, caídas de muchos árboles e inundaciones en muchas zonas aledañas a la costa que a su vez afectaron miles de hectáreas de zonas agrícolas.

El Puerto de Manzanillo cerró sus instalaciones durante el paso del huracán Patricia, sufrió pequeños daños en su infraestructura como techos y ventanas, pero nada que pusiera en riesgos sus operaciones por lo que reanudaron rápidamente sus actividades.

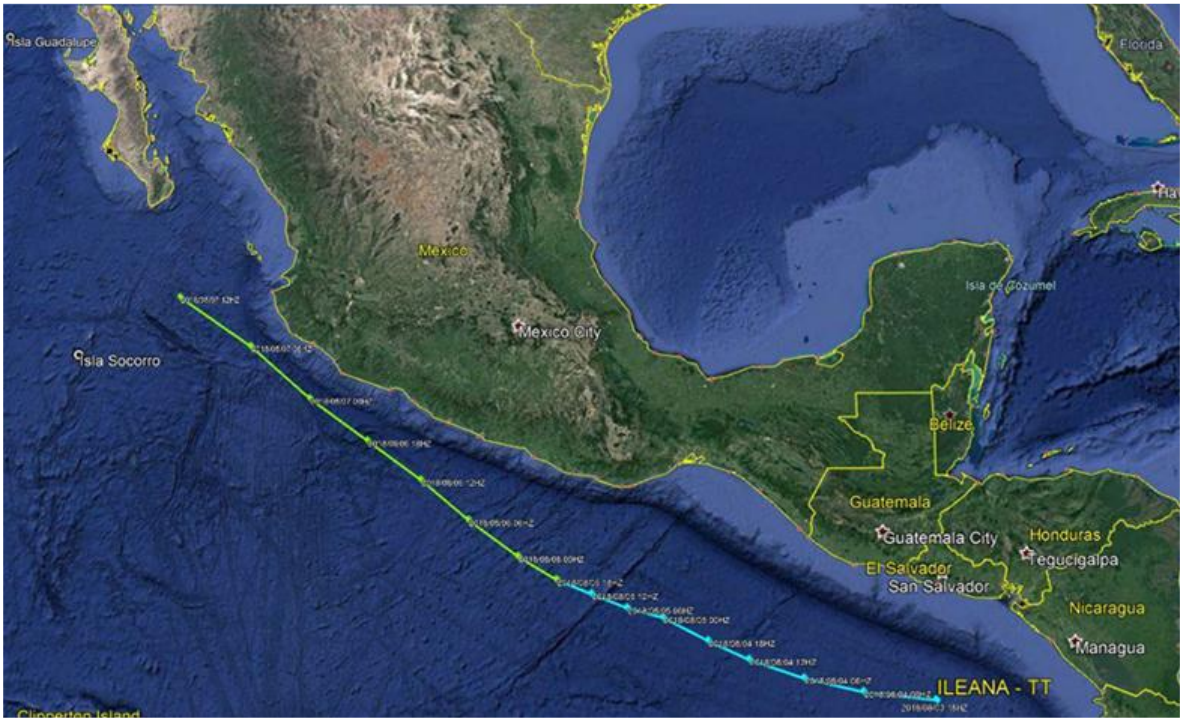
El Centro Nacional de Prevención de Desastres (CENAPRED) reportó un total de 4,008.70 millones de pesos en pérdidas ocasionadas por el huracán Patricia, de los cuales el estado de Colima sufrió 1,744.1 millones de pesos. De primera instancia parece una enorme cantidad, pero

comparada con los 10,000 millones de pesos que había pronosticado el consultor de desastres naturales para la Comisión Económica para América Latina y El Caribe (CEPAL), sólo se perdió el 40% de lo pronosticado.

i) Tormenta Tropical Ileana del 2018

A las 16:00 horas del 4 de agosto se formó la depresión tropical “Once-E” al sur del Golfo de Tehuantepec; un día después se convirtió en tormenta tropical, al Sur de las costas de Guerrero y Oaxaca, y se le nombró Ileana (ver Figura 3.29).

Figura 3.29 Trayectoria de la Tormenta Tropical Ileana del 2018**.**



Fuente: Comisión Nacional del Agua (CONAGUA), 2019.

El mayor acercamiento de la tormenta a las costas fue a el día 6 de agosto a las 22:00 horas cuando se ubicó 130 km al Sur-Suroeste de Manzanillo con vientos máximos sostenidos de 95 km/h. El martes 7 de agosto a las 10:00 horas la tormenta Ileana fue absorbida por las bandas nubosas del huracán John frente a las costas de Jalisco y Nayarit, habiendo recorrido un total de 2,300 km y durado 66 horas.

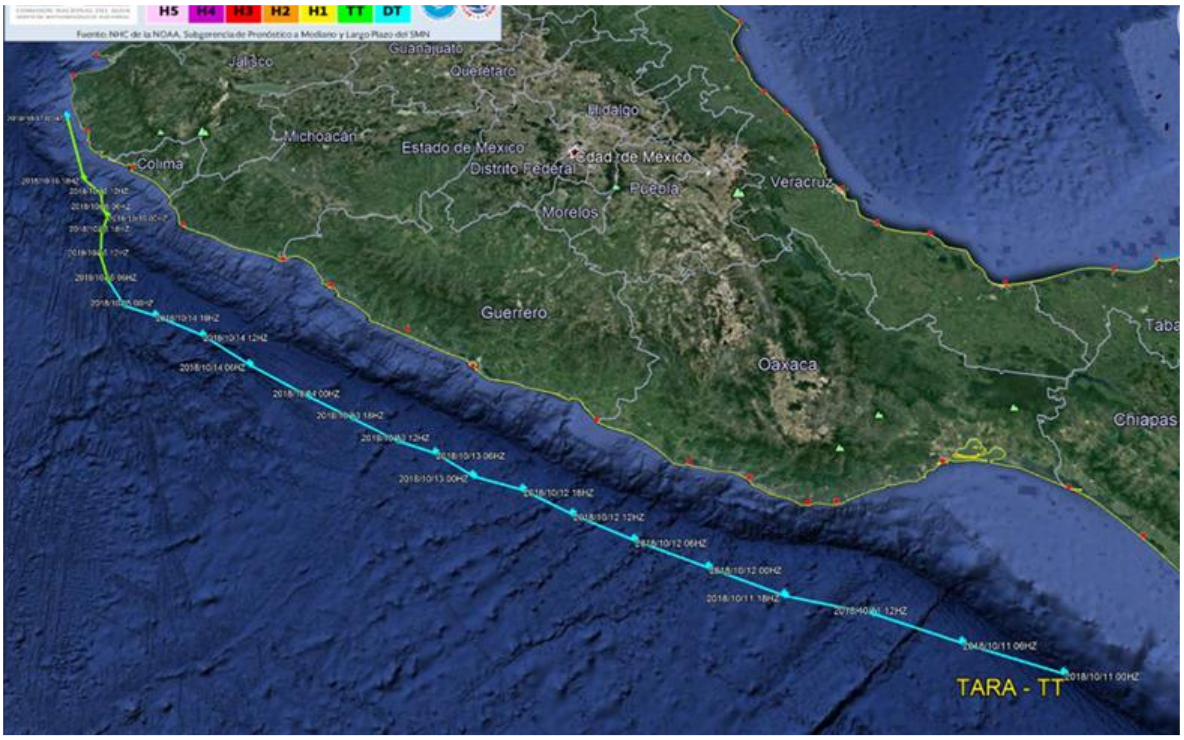
Si bien John fue de mayor categoría que Ileana, quien ni siquiera alcanzó la categoría 1 de huracán, fue Ileana quien provocó mayor precipitación en nuestra zona de estudio, pues pasó

mucho más cerca de Colima que John, acumulando una precipitación total de 50 mm. El periódico "El Universal" reportó 4 muertes debidas al huracán Ileana; 3 de ellas ahogadas por inundaciones y desbordes de ríos en Chilpancingo, Guerrero, y la cuarta ahogada en la playa por el fuerte oleaje.

j) Tormenta Tropical Tara del 2018

El 14 de octubre se formó la depresión tropical 22-E a 125 km al Sursuroeste de Lázaro Cárdenas, con desplazamiento hacia el Oeste-Noroeste a 9 km/h (ver Figura 3.30).

Figura 3.30 Trayectoria del Huracán Tara del 2018**.**



Fuente: Comisión Nacional del Agua (CONAGUA), 2019.

3.8.2 Registro Estadístico de Huracanes.

México es un país vulnerable a la influencia de los ciclones tropicales que se generan tanto en el Océano Atlántico como en el Pacífico. La fuerza destructiva de algunos de ellos en los últimos años ha provocado que se crea que estos meteoros se han incrementado en frecuencia y/o intensidad como consecuencia del cambio climático global.

En el Pacífico se genera la mayor densidad de ciclones tropicales, aunque por las circunstancias oceánicas y atmosféricas la mayoría de ellos tienden a alejarse de las costas mientras que en un porcentaje menor llegan a tocar tierra, no ocurriendo así para el Atlántico. El estudio de un periodo mayor de 50 años muestra que no existe una tendencia clara hacia el aumento en intensidad o frecuencia de los ciclones y que Jalisco es uno de los estados con mayor impacto de estas tormentas en el Océano Pacífico.

3.8.2.1 Incidencia de Huracanes.

Al revisar las estadísticas se encuentra que lo mismo ha habido años y épocas de mínima actividad ciclónica, que otros con numerosos huracanes y tormentas. Desde luego, mientras más tormentas se formen en una temporada, mayor será el número de ellos que puedan convertirse en huracán y mayores también las probabilidades de que algunos alcancen gran intensidad.

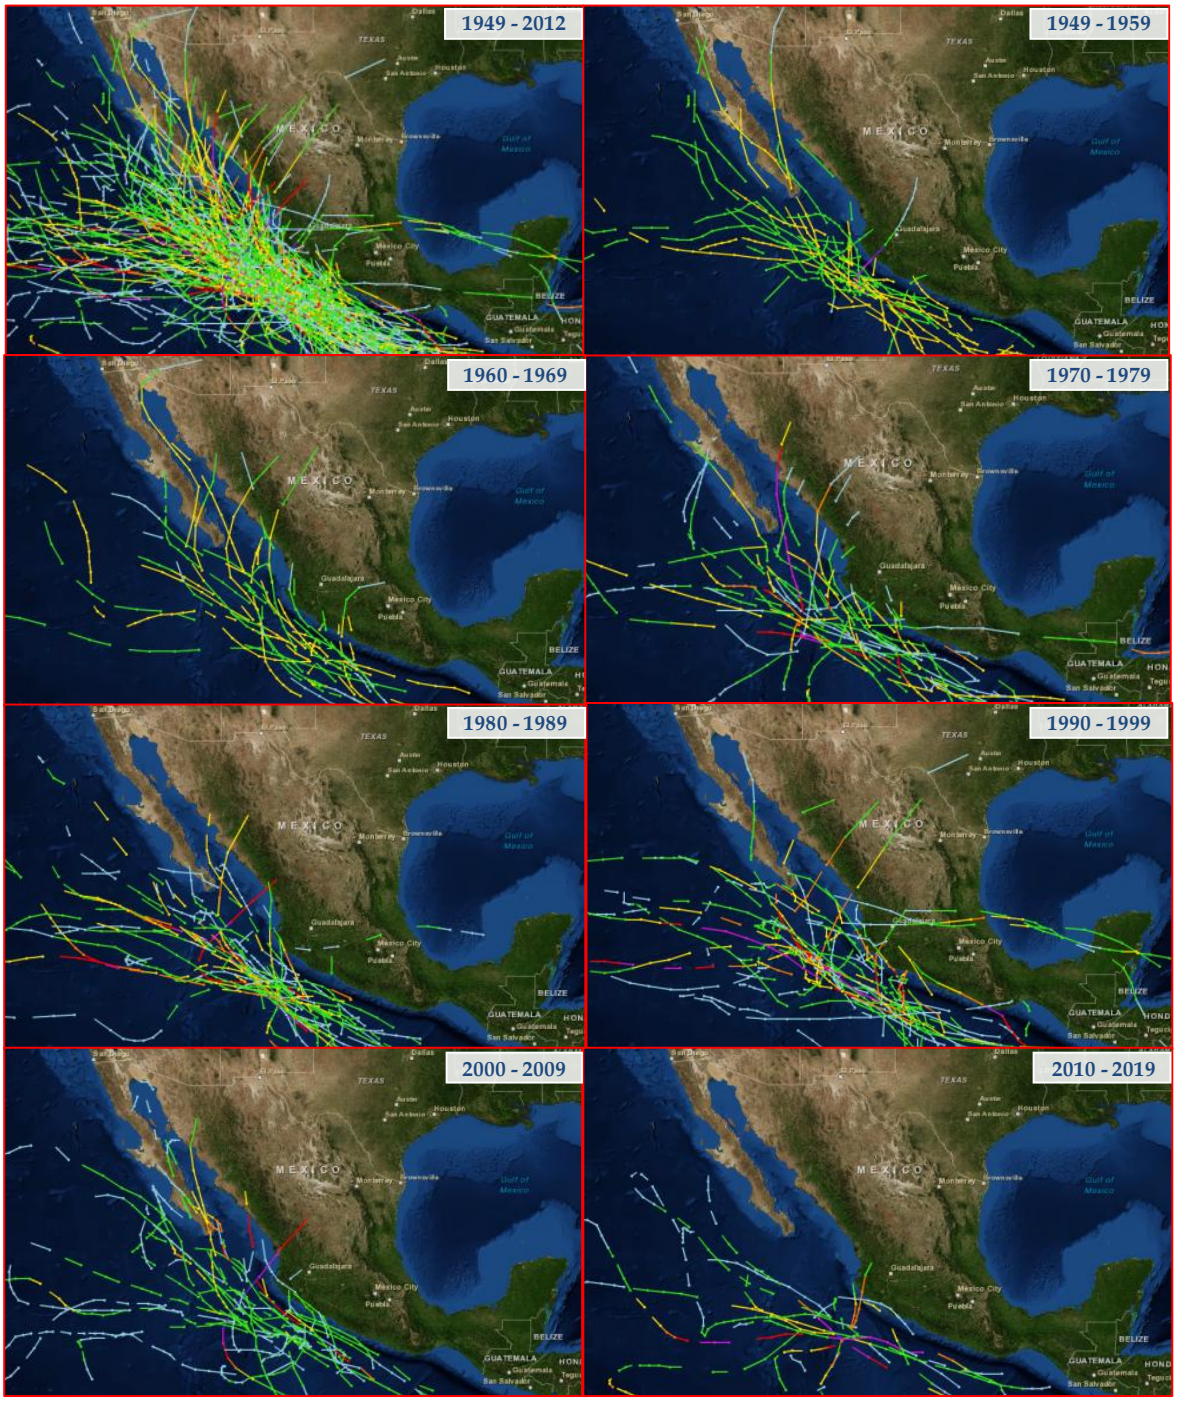
En la Figura 3.31 se muestran las trayectorias de los ciclones tropicales que han ocurrido en el Océano Pacífico, década por década, desde 1949 al 2012. Se observa que desde la década de los 60's a la fecha, las trayectorias muestran mayor densidad que en la primera (1950-1959). Lo anterior puede deberse, muy probablemente, a que en dicha década aún no operaban los satélites ambientales y por ello un número significativo de ciclones tropicales pudieron haber pasado inadvertidos. Esto significa, que probablemente no es un cambio real en el número de ciclones tropicales.

En contraste con el Océano Atlántico, en el Pacífico se observa un ligero aumento en el número de trayectorias en la década de 1980 a 1989. Por lo demás, los patrones de trayectorias son bastante consistentes entre década y década.

Por otra parte, se observa que, históricamente, México se ve afectado por ciclones tropicales desde el inicio de la temporada, la cual inicia el 15 de mayo y termina el 30 de noviembre. Los meses de julio, agosto y septiembre son los que presentan un mayor número de ciclones tropicales, y de ellos, el de septiembre es el que presenta un mayor número de ciclones que afectan directamente nuestras costas. En noviembre son ya muy pocos los ciclones que pueden presentarse, pero todavía existe una probabilidad de que haya afectaciones por estos fenómenos en nuestro país.

Las trayectorias menos climatológicas, es decir, las que menos siguen un patrón histórico, se dan al principio y al final de la temporada. Conforme avanza la temporada de junio a octubre la probabilidad de recurve e incidencia en México aumenta. Lo anterior produce que la mínima probabilidad de incidencia en México ocurra en julio.

Figura 3.31 Trayectorias de los Huracanes que han Pasado por el Océano Pacífico (1949-2019).

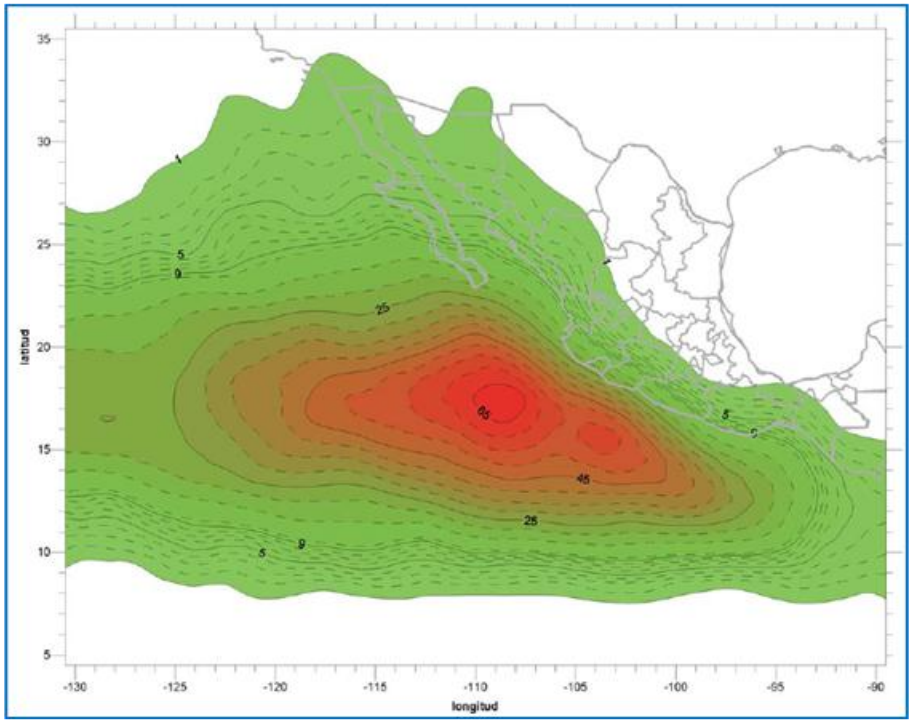


Fuente: National Oceanic and Atmospheric Administration (NOAA), 2019.

En el mes de junio se observa que la mayoría de los ciclones tropicales que recurvan a tierra afectan principalmente las costas centrales, y muy pocos llegan al noreste del país. En cambio, en julio la tendencia de las trayectorias es hacia el noroeste, con la posibilidad de que los ciclones se adentren a tierra en aquella zona del país. En el mes de agosto se observa que las trayectorias se definen más hacia el norte, afectando los estados de Sonora, Baja California, Baja California Sur y el norte de Sinaloa, principalmente.

De acuerdo con el registro de ciclones tropicales, es posible identificar una zona con mayor densidad de ciclones tropicales que se localiza en las coordenadas 109° oeste y 16° norte, ver Figura 3.32. Asimismo, se observa claramente la disminución de estos valores en los sitios donde se ubican zonas montañosas. Cabe resaltar que la isolínea de 10 ciclones tropicales va por la costa del Pacífico mexicano hasta cruzar el sur de la península de Baja California Sur, es decir que cerca de la zona de proyecto se tienen fácilmente frecuencias de hasta 10 ciclones tropicales en 60 años.

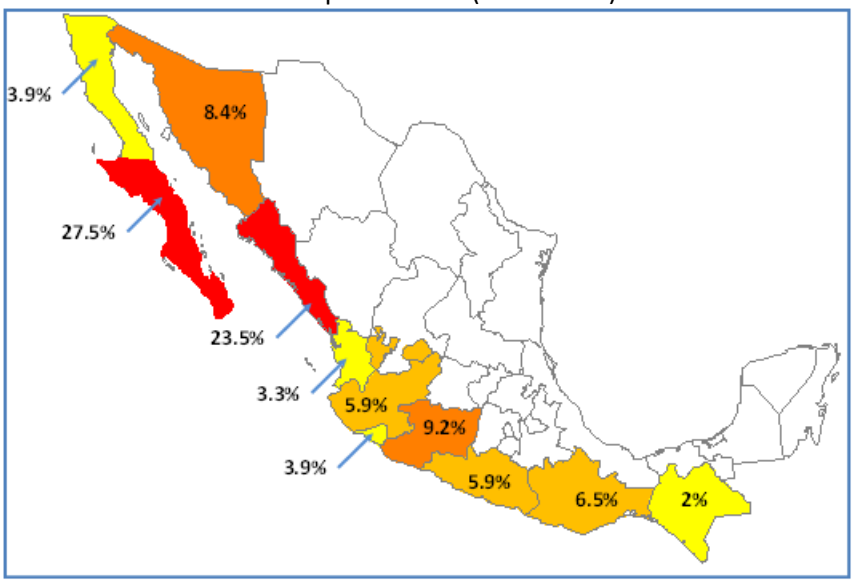
Figura 3.32 Distribución del Número de Tormentas Tropicales y Huracanes para el Océano Pacífico (1949-2019)**.**



Del análisis desarrollado, se observa que hay alternancia de periodos con mayor incidencia de ciclones tropicales de 1982 a 1994, mientras que en 1993 a 2004 predominó un menor número de ellos, asimismo, no se observa una tendencia al incremento de la intensidad de los huracanes.

Sin embargo, se puede apreciar que los huracanes categoría 5 son menos frecuentes. Al revisar la frecuencia de los ciclones que inciden sobre la costa, se observó que en 1981 y 2006 se dan las mayores frecuencias. Por otra parte, de acuerdo con el período estudiado, se observaron 755 ciclones tropicales, de los cuales 153 han tocado las costas del Pacífico mexicano, observándose que el Estado de Colima presenta un 3.9% de frecuencia relativa (ver Figura 3.33).

Figura 3.33 Incidencia de Huracanes en las Costas Mexicanas del Océano Pacífico por Estados (1949-2019)**.**



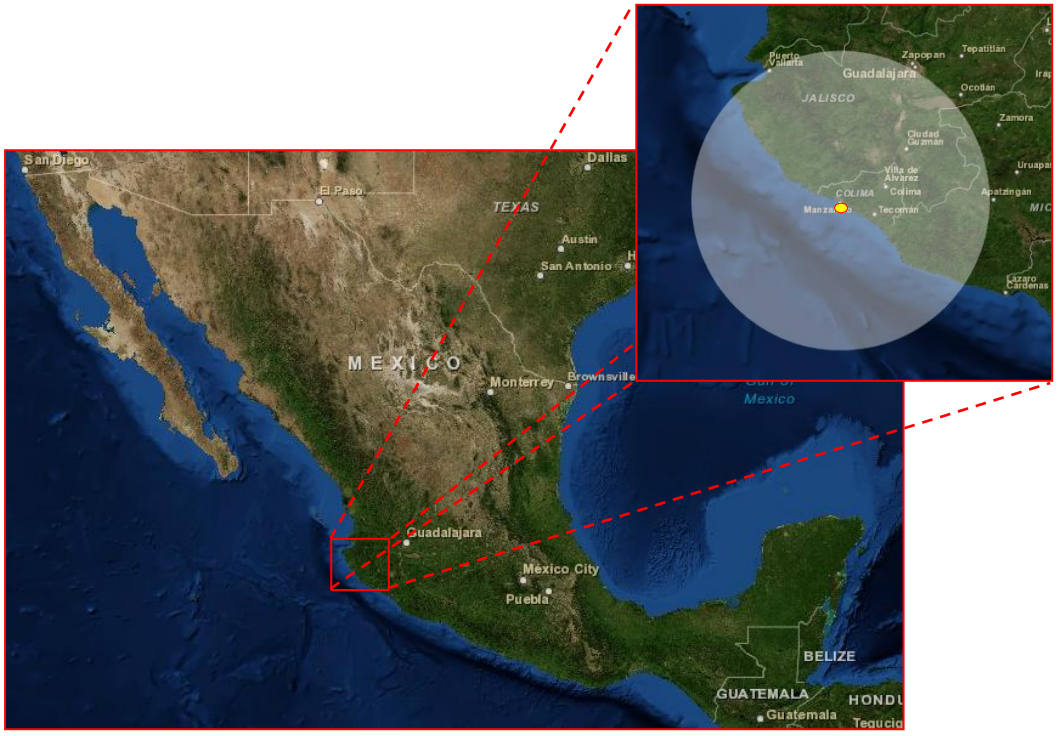
3.8.2.2 Eventos Climáticos Extremos en la Zona de Estudio.

Tal como se ha descrito en los párrafos anteriores, la zona de estudio es una región que se azotada por perturbaciones atmosféricas de gran magnitud, principalmente durante los meses de julio a septiembre, con los efectos consiguientes, tales como oleajes de gran magnitud, mayores a los normales y sobreelevaciones temporales del nivel medio del mar generados por el empuje del viento ciclónico sobre la superficie del agua.

Para determinar los efectos de estos ciclones en la zona de proyecto, fue realizado un análisis de eventos extremos actuando sobre el lugar a partir de los registros de los meteoros más significantes históricamente, que van desde las depresiones tropicales hasta los huracanes

categoría 5 en la escala Saffir-Simpson, para tal caso fue delimitada una zona de 200 km (108 millas náuticas aproximadamente, ver Figura 3.34), con el objeto de identificar las principales tormentas que han pasado o tocado tierra en la cercanía de las costas de Manzanillo.

Figura 3.34 Delimitación de la Zona de Estudio**.**



Fuente: Elaboración propia, 2019

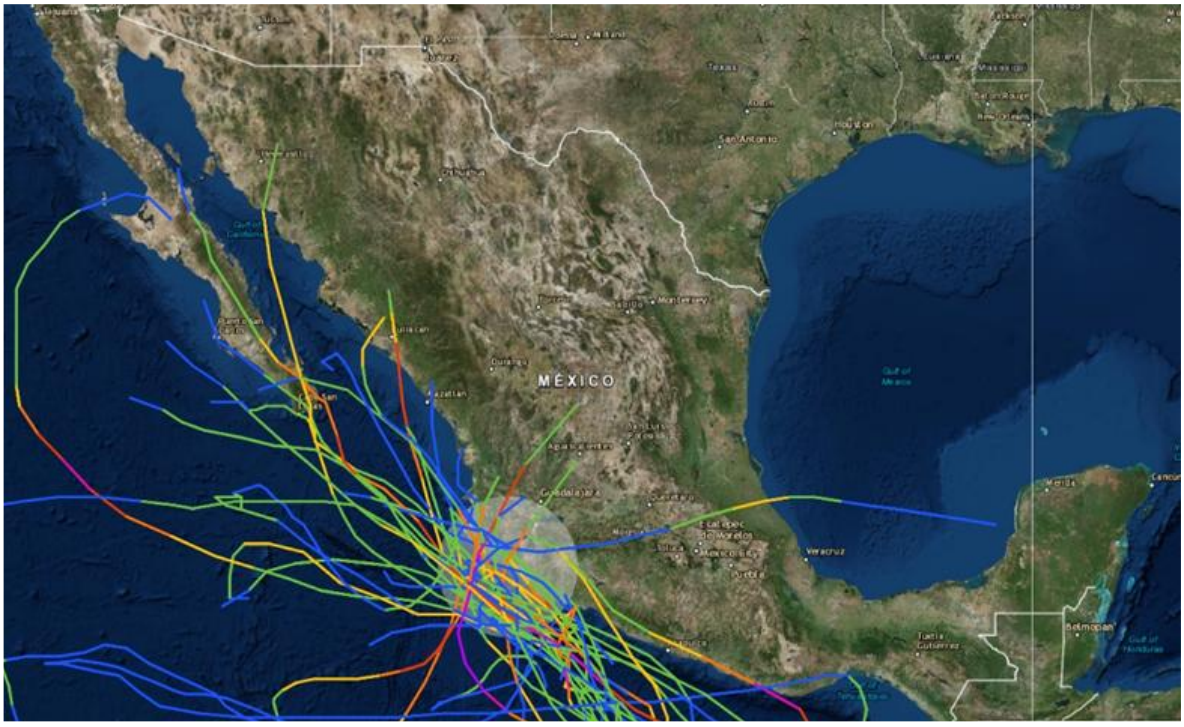
De acuerdo con los registros del National Hurricane Center, en el lapso de 1949 a 2018, se identificaron un total de 94 eventos ciclónicos que se presentaron en la zona de estudio, ver Figura 3.33. Del total de ciclones que se han presentado en la zona de estudio, el 44% corresponden a tormentas tropicales, mientras que los huracanes categoría 1 representan el 33% y 13% corresponde a huracanes categoría 2, el restante 9% se encuentra integrado por huracanes categoría 3 a 5 y el restante 2% corresponde a depresiones tropicales.

Es importante comentar, que las tormentas identificadas corresponden a la clasificación del tipo de ciclón tropical con el que fueron identificadas, más no implica necesariamente, que se hayan presentado con esa categoría en la zona de estudio. De acuerdo con el análisis desarrollado, se identificó el estado de cada tormenta en su posición más cercana a la zona de estudio, el 69%

corresponde a tormentas y depresiones tropicales, los huracanes categoría 1 disminuyen hasta el 25% y el restante 7% se encuentra integrado por huracanes categoría 2 a 5, ver Figura 3.35.

Ahora bien, como se ha comentado anteriormente, el monitoreo y registro de los ciclones tropicales en el Océano Pacífico es reciente, por lo cual de los 94 ciclones identificados no todos cuentan con los datos suficientes de mediciones de sus características (viento, presión y velocidad) para desarrollar su análisis y determinar su influencia sobre la zona de estudio, por tal motivo, de los 94 eventos se identificaron 43 ciclones con datos suficientes para ser evaluados, ver Tabla 3.9 y Figura 3.36. Con los datos de esos 43 eventos, se realizará el análisis extremal.

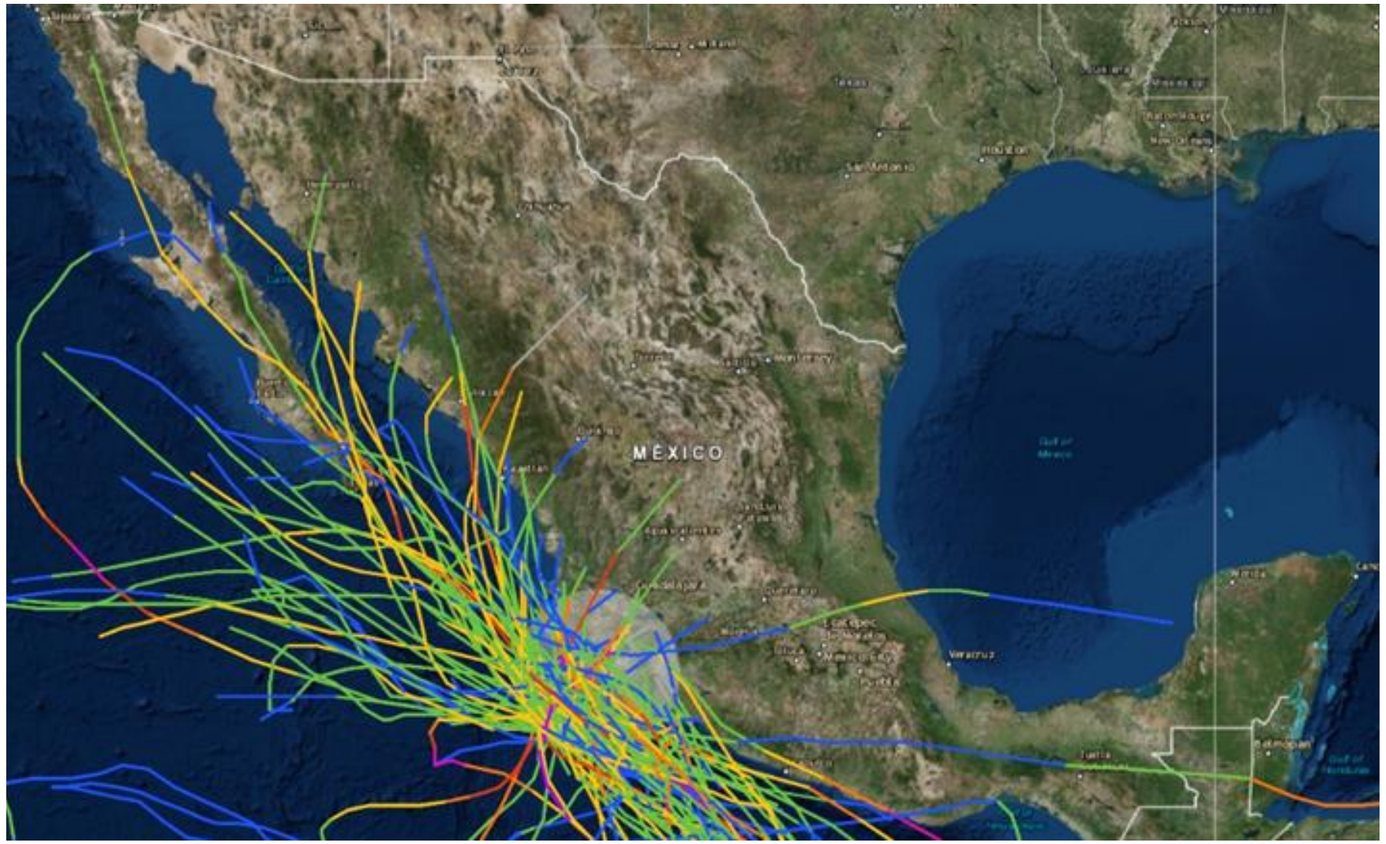
Figura 3.36 Delimitación de la Zona de Estudio**.**

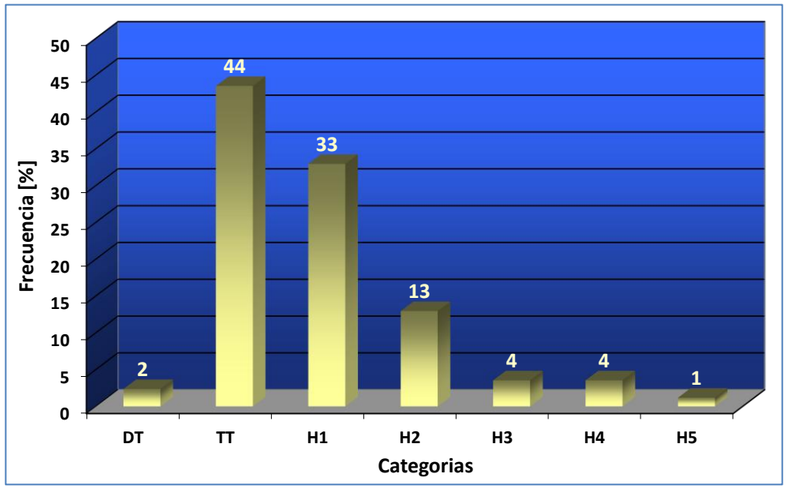


Fuente: National Oceanic and Atmospheric Administration (NOAA), 2018.

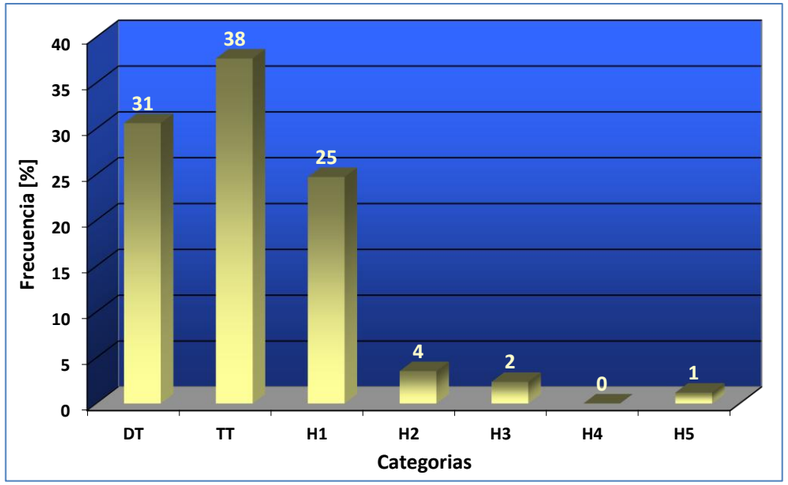
Del total de ciclones presentados en la zona de estudio desde 1949 a la actualidad, la mayor parte de eventos corresponde a depresiones y tormentas tropicales, solo la cuarta parte alcanza la categoría de huracán entre 1 y 5. De acuerdo con esta valoración, se observa que en la zona ha visto afectada por un huracán de categoría 5 en los últimos 24 años, por otra parte, los huracanes categoría 2 a 4 en conjunto representan el 6% de los eventos extremos.

Figura 3.35 Eventos Ciclónicos en la Zona de Estudio (1949-2019).





A) Total de eventos ciclónicos que se presentaron en la zona de estudio, clasificados de acuerdo a su desarrollo general.



B) Total de eventos ciclónicos que se presentaron en la zona de estudio, clasificados de acuerdo a su desarrollo particular en la zona de

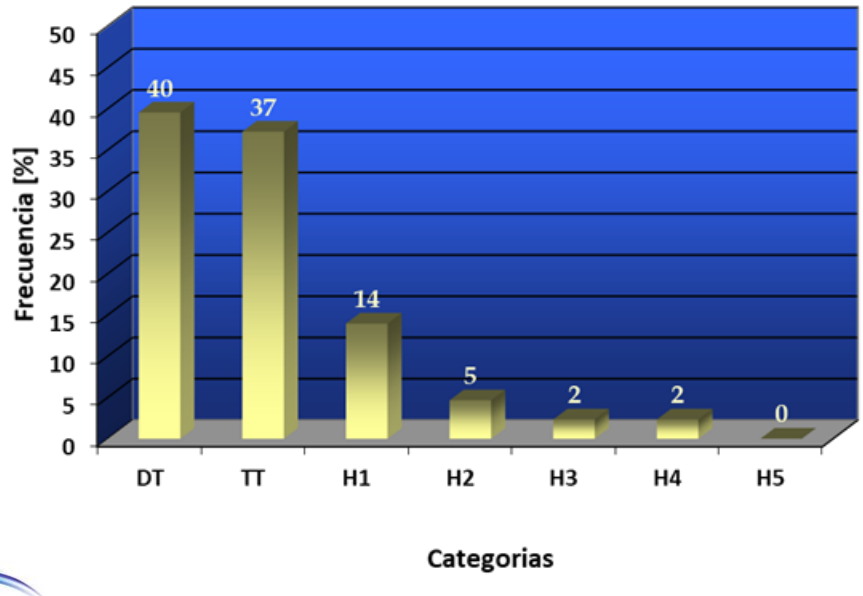
Es importante comentar que la clasificación de las tormentas para este proyecto corresponde a la clasificación del tipo de ciclón tropical con el que se haya presentado en su posición más cercana a nuestra zona de estudio. De acuerdo con el análisis desarrollado se identificó el estado de cada tormenta; el 40% está conformado por las depresiones tropicales, mientras que el 37% son tormentas tropicales; de la cuarta parte restante de eventos, el 14% son huracanes categoría 1, el 5% huracanes de categoría 2, y el 4% restante está repartido entre huracanes de categoría 3 a la 5, ver Figura 3.37.

Figura 3.37 Distribución Frecuencial del Total de Ciclones en la Zona de Estudio**.**



3.8.3 Oleaje Asociado a Eventos Extremos.

Parte fundamental en cualquier trabajo de ingeniería de costas consiste en determinar las características de oleaje que un evento extraordinario -concretamente un huracán-, puede generar en la zona en estudio. La importancia de conocer estas características radica en que de ellas se derivan las condiciones máximas extremas a las cuales estará sujeto un proyecto costero y que generalmente, representan los extremos climáticos más significativos.

Sobre esta base, fue realizado un análisis de oleaje extremal a partir de la base de datos de huracanes con que se cuenta. Para determinar las características del oleaje que potencialmente pudo haber generado cada evento meteorológico, se analizó su trayectoria y mediante la implementación del método del Huracán Standard (con registros de presión central, posición del meteoro, velocidad de viento y fecha de ocurrencia), se determinaron las características del oleaje en la zona de generación y de decaimiento, ver Tabla 3.10.

Para definir la relación entre la altura de ola asociada a huracanes y su distribución en el tiempo, al conjunto de resultados mayores le fue aplicada la metodología para correlacionar el período de retorno, asociándolo a los valores máximos registrados. La serie de datos (altura de ola-período de retorno) fue procesada empleando las curvas de ajuste a una distribución de probabilidad tipo Weibull, dado que este modelo matemático representa el mejor ajuste en función de la menor desviación estándar de la muestra.

Para el análisis, se han seleccionado de cada evento la altura de ola mayor presentada, es decir, se tienen alturas de ola máximas anuales y con ellas se representan el papel probabilístico de Weibull. Los puntos negros son los datos reales de la serie de datos y la línea roja representa el ajuste de Weibull. En el eje y izquierdo se presenta la probabilidad de ocurrencia y en el eje y derecho el periodo de retorno en años. El eje x representa la altura de ola significante.

En la Figura 3.38 se presentan la probabilidad conjunta de las alturas de ola superiores a 2.0 m a periodos picos. Se extraen los valores representativos para los diferentes periodos de retorno de altura de ola y periodo en la zona de generación que se presentan en la Tabla 3.11.

De esta manera, se tiene un gráfico de ajuste probabilístico en el cual se asocia la altura de ola para un evento extremo correlacionándolo con un periodo de retorno o probabilidad de ocurrencia. Dado que estas alturas de ola extremal se presentan en la zona de generación, resulta adecuado conocer la altura de ola de decaimiento, ver Figura 3.39

Tabla 3.10 Eventos Ciclónicos Evaluados para la Zona de Estudio.

En comparación con las condiciones de régimen medio, las direcciones más frecuentes están dentro del cuadrante SW. Por lo que se asocia que los eventos más energéticos provienen de este cuadrante.

3.8.4 Marea de Tormenta.

Otro fenómeno por considerar es el efecto de marea o variación del nivel del mar asociado a los huracanes. Dicho fenómeno se presenta de manera importante según los testimoniales en la zona.

La marejada de tormenta es el incremento en el nivel medio del mar provocado por la fuerza cortante que sobre la masa de agua ejercen vientos de velocidades altas, generalmente asociados a huracanes (y, sólo de manera secundaria, por la reducción de la presión barométrica a nivel del mar entre el ojo de la tormenta y la región externa), provocando una acumulación de masa en profundidades someras próximas a la línea de costa.

Se estima que la elevación temporal del nivel del mar es que por cada 100 milibares (mb) que baje en la presión barométrica, se espera una elevación de un 1 m del nivel del mar. La magnitud de la marea en un determinado lugar también es función del radio de los vientos máximos del huracán, la velocidad de avance del sistema y la batimetría frente a la costa. Es aquí

donde surge la dificultad para pronosticar los niveles de mareas de tormenta. Por otra parte, los registros históricos indican que un aumento del nivel promedio del mar puede ser insignificante o puede ser hasta de unos 7.5 metros (24.60 pies).

Esta sobreelevación del nivel del mar puede provocar, por un lado, la generación de inundaciones en el área de tierra próxima a la costa, sobre todo en lugares donde la pendiente de la playa y la placa continental son muy suaves y por otra parte, ocasionar el incremento y acercamiento de la franja de rompientes de las olas a la costa por el aumento de profundidad.

Para determinar las características de la marejada de tormenta que potencialmente se puede generar cada evento meteorológico, se analizó su trayectoria y mediante la implementación del método del Huracán Standard (con registros de presión central, posición del meteoro, velocidad de viento y fecha de ocurrencia), y los métodos de Per Brunn y Keulegan-Per Brunn para determinar la magnitud del ascenso del nivel del mar a causa de la marea de tormenta; asociada a viento y presión de los fenómenos extremos.

Con estos métodos se toma en cuenta la diferencia de presiones presentada por el huracán, el radio del huracán, el movimiento y velocidad de desplazamiento de la tormenta y las características de profundidad de la playa en la zona de estudio, ver Tabla 3.12.

Posteriormente, se aplicó el método de Gumbel para asociar las variables de interés con su periodo de retorno. Al ser una consecuencia de un evento extremo al que puede relacionársele un período de retorno, la marea de tormenta también está asociada con un período de retorno o una probabilidad de excedencia, ver Figura 3.41.

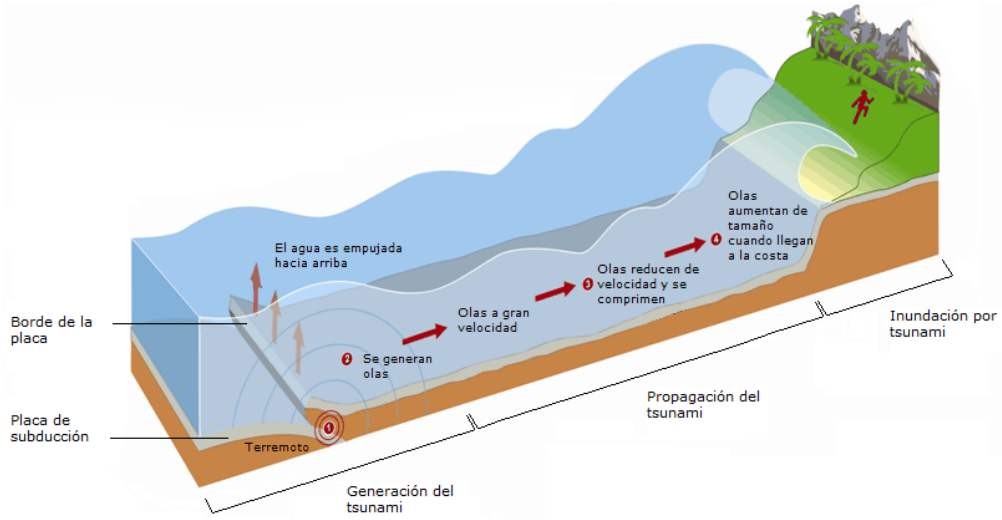
3.9 TSUNAMIS.

3.9.1 Introducción.

El término tsunami es japonés y se utiliza para designar el fenómeno que en español se denomina maremoto. Es una serie de ondas largas gravitacionales (Longitud de onda mayor que su altura) que se forman en el océano al ocurrir alguna alteración de corta duración, pero gran extensión en su superficie libre. Los sismos grandes con profundidad focal relativamente superficial son los causantes de la mayoría de estas ondas, aunque también pueden ser causadas por erupciones de volcanes sumergidos, impacto de meteoritos, deslizamientos submarinos o explosiones nucleares.

En su zona de generación, mientras se desplazan por aguas profundas mar afuera, las olas de los tsunamis son de gran longitud (cientos de kilómetros) y altura pequeña (centímetros). Debido a la gran velocidad a la que se propagan (cientos de kilómetros/hora) son visualmente indetectables desde embarcaciones y aviones. Sus periodos (lapso entre el paso de dos olas sucesivas) son de 15 a 60 minutos, en la Figura 3.42 se muestra gráficamente la generación de un Tsunami; es importante no confundir con las olas cortas de tormentas generadas por el viento que comúnmente llegan a las costas, ni con las ondas mucho más extensas de las mareas que de una a dos veces arriban todos los días.

Figura 3.42 Generación de Tsunamis**.**



Fuente: http://www.prsn.uprm.edu/

A medida que las ondas del tsunami entran a las aguas superficiales de la plataforma continental, su velocidad disminuye, pero su altura aumenta considerablemente (del orden de decenas de metros) y pueden ocasionar inundaciones repentinas o una retirada de la mar seguida por una inundación. La inundación se manifiesta como una marea que sube rápidamente y en ocasiones como una pared de agua que avanza sobre la costa, pudiendo penetrar varios kilómetros tierra adentro alcanzando alturas de hasta 30 metros, como fue el caso de Sumatra en el 2004 y de Japón en el 2011. No siempre la primera ola es la más alta, en ocasiones es la tercera o cuarta ola, mismas que se suceden en intervalos de 30 minutos y continúan llegando con menor altura durante al menos 24 horas.

3.9.2 Características de los Tsunamis.

Para que un sismo genere un tsunami, es necesario que:

a. El hipocentro (punto de origen del sismo, en el interior de la Tierra. Lugar donde empieza la ruptura que se extiende formando un plano de falla) del sismo, o una parte mayoritaria de su área de ruptura, esté bajo el lecho marino a una profundidad menor a 60 km (sismo superficial).

b. Ocurra en una zona de hundimiento de borde de placas tectónicas; es decir, que la falla tenga movimiento vertical: que no sea solamente de desgarre, con movimiento lateral.

c. En cierto lapso, el sismo libere suficiente energía y que ésta se transmita eficientemente. Aún no existe algún modelo teórico ni método operacional totalmente satisfactorio que permita determinar si un sismo es tsunami-génico (generador de tsunami) ni de que tamaño (magnitud, intensidad o altura de ola) será el tsunami generado.

Por tratarse de trenes de ondas marinas, los tsunamis se pueden caracterizar por su período, altura de onda, longitud de onda y velocidad de propagación, que son atributos comunes a ellas.

- Período: T, se define como el tiempo que transcurre entre el paso de dos ondas sucesivas por un mismo punto de observación. Para tsunamis de origen cercano, el período es de unos 7 a 30 minutos; y para los de origen lejano, entre 30 a 70 minutos.

- Altura de onda: H, es la distancia vertical entre el seno o valle y la cresta, mientras el tsunami se dirige a tierra.

- Longitud de onda: L, es la distancia que separa a dos crestas sucesivas. Se estima que la longitud de onda inicial es aproximadamente igual a la dimensión mayor del área dislocada.

- Velocidad de propagación: v, La velocidad de propagación del tsunami está determinada por la profundidad del agua que está directamente sobre el sismo y la gravedad terrestre.

Puede observarse que la velocidad de propagación del tsunami es función solamente de la profundidad del sector del océano por el cual viaja. Por ejemplo, un tsunami que atraviesa una parte del océano donde la profundidad es de 4,000 m, tendrá una velocidad de 200 m/s o 720 Km/h. Si asumimos como profundidad promedio del océano Pacífico la mitad de la profundidad máxima que es 11,022 m, es decir, 5,511 m, el tsunami viajaría a 837 Km/h; velocidad similar a la de un avión jet.

Como la velocidad del tsunami es mayor en un mar profundo que en un mar superficial, cuando el tsunami viaja en un mar de profundidad variable, la dirección de propagación gira gradualmente hacia la zona menos profundidad. Este fenómeno se denomina «Refracción de ondas», y en su tratamiento se aplica la Ley de Snell, de la Óptica.

3.9.3 Tipos de Tsunamis.

Los tsunamis se clasifican en el lugar de arribo a la costa, según la distancia (o en el tiempo de desplazamiento) desde su lugar de origen, en:

a. Tsunamis locales. El lugar de arribo a la costa está muy cercano o dentro de la zona de generación (delimitada por el área de dislocación del fondo marino) del maremoto; por tiempo de desplazamiento: a menos de una hora. La inundación queda confinada a lo largo de la costa en el área del terremoto y a distancias de 100 km aledañas al área del terremoto. Ejemplo: el generado por un sismo en la Fosa Mesoamericana frente a Michoacán el 19 de septiembre de 1985, que tardó sólo 30 segundos para llegar a Lázaro Cárdenas, y 23 minutos a Acapulco.

b. Tsunamis regionales. El litoral invadido está a no más de 1,000 km o a pocas horas de viaje de la zona de generación (lapso de 2 a 4 horas desde su origen). Ejemplo: el provocado por un sismo en las costas de Colombia el 12 de diciembre de 1979, que tardó 4 horas para llegar a Acapulco.

c. Tsunamis lejanos (Remotos o transpacíficos). El sitio de arribo está muy alejado, en el Océano Pacífico, a más de 1,000 km de distancia de la zona de generación, a aproximadamente medio día o más de viaje. Ejemplos: el ocurrido tras un sismo en Chile el 22 de mayo de 1960; tardó unas 13 horas en llegar a Ensenada (México), y el maremoto generado en Japón el 16 de mayo de 1968; demoró 14 horas en arriba a Manzanillo (México).

El proceso de transformación de la onda larga del tsunami es el mismo que el de la onda corta, está sometido a los mismos procesos de refracción, difracción y someramiento. Este último se produce cuando la onda siente el fondo se acorta, y reduce su velocidad a la vez que se peralta y aumenta su altura de ola.

Existen 3 tipos de fallas que pueden producir terremotos:

- Normal: uno de sus bloques cae bajo la acción de la gravedad y de las fuerzas de extensión que actúan en la corteza. Las fuerzas tectónicas actúan dilatando o expandiendo el medio en forma perpendicular a la falla.

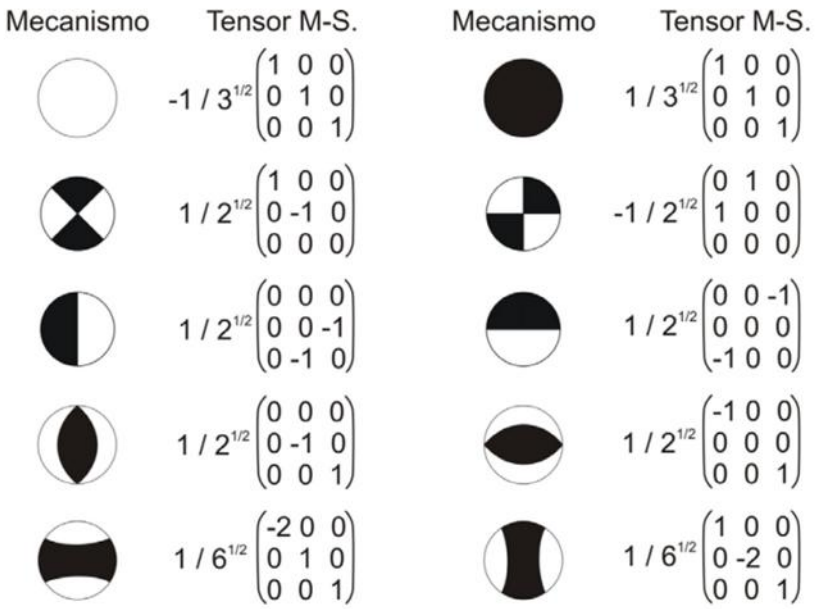
- Inversa: Uno de su bloque es empujado hacia arriba producto de las fuerzas que actúan en la corteza. Las fuerzas tectónicas actúan comprimiendo el medio y en forma perpendicular a la falla.

- Longitudinal: Este es el tipo de falla que se produce cuando las fuerzas tectónicas actúan en dirección opuesta a ambos lados de la falla, pero en forma paralela a ésta. Como consecuencia los bloques son desplazados horizontalmente.

Se denomina lo que es mecanismo focal de un sismo. Este es el resultado del análisis de las ondas sísmicas generadas por un terremoto, a través de éste se puede determinar las características de la falla que ha producido el sismo. Una manera para calcular el mecanismo

producido puede ser el cálculo del tensor de momento focal (MF). En la Figura 3.43 se muestra algunos mecanismos asociados a su tensor.

Figura 3.43 Generación de Tsunamis**.**



Fuente: Reduca (Geología). Serie Tectónica. 2 (6): 1-91, 2010. ISSN: 1989-6557

En la Figura 3.44 se ejemplifican los tipos de mecanismos que se producen asociados a la Falla de San Andrés, o al sismo de subducción de las costas de México.

3.9.4 Propagación y tiempo de desplazamiento de los Tsunamis.

La longitud de las olas de los maremotos (varios cientos de kilómetros) es mucho mayor que la profundidad de las aguas oceánicas por las que se desplazan. Esta propiedad (denominada de onda superficial) hace que, en primera aproximación, su velocidad de propagación dependa exclusivamente de la profundidad. Esto permite determinar la velocidad de propagación correspondiente a todos los puntos oceánicos de los que se tengan datos batimétricos, y asimismo a cuantificar el tiempo de desplazamiento del tsunami entre dos lugares (en particular el de origen y el de arribo a la costa), a lo largo de una trayectoria que una esos puntos. La más cercana a la realidad es el arco de círculo máximo común a ambos puntos, ver Figura 3.45.

En un sistema de alerta, para poder avisar a tiempo a la población de la llegada de un tsunami cuya generación ya se haya confirmado, estas cartas constituyen un recurso muy útil.

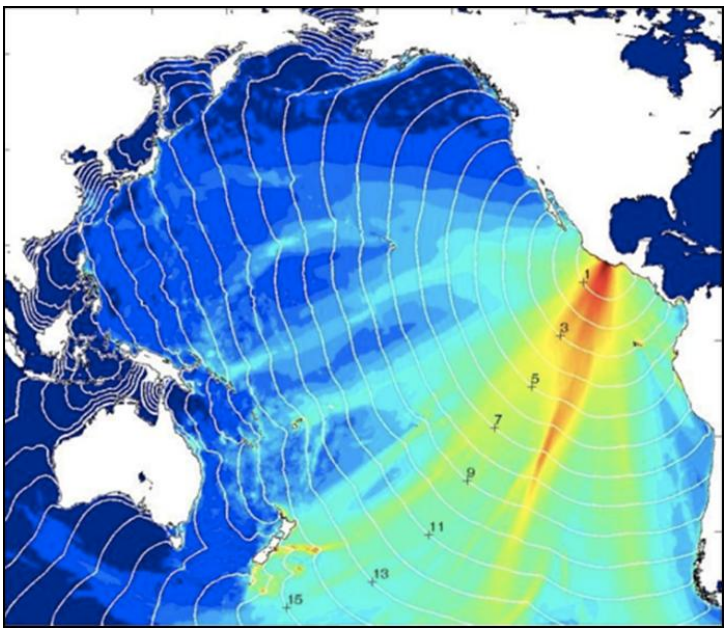
Figura 3.45 Estimación de Horas de Arribo en la Hipótesis de un Tsunami en México**.**



Fuente: http://skyalertblog.blogspot.com/

En 1965 la Comisión Oceanográfica Intergubernamental de la UNESCO estableció el Sistema de Alerta de Tsunamis del Pacífico (Pacific Tsunami Warning Center, PTWC) con sede en Honolulu, Hawái. Opera las 24 horas del día durante los 365 días del año y sus funciones son monitorear la actividad sísmica y las fluctuaciones excesivas y rápidas del nivel del mar registradas mediante una red extensa de instrumentos detectores, evaluar la existencia o la potencialidad de generación de un tsunami, y diseminar esta información por medio de mensajes de observación y de alerta a los países miembros.

Actualmente integran este grupo los siguientes países: Australia, Canadá, Chile, China, Colombia, Costa Rica, Ecuador, Estados Unidos de América, Federación Rusa, Fiji, Filipinas, Francia, Guatemala, Reino Unido, Indonesia, Islas Cook, Japón, México, Nicaragua, Nueva Zelanda, Perú, República Democrática Popular de Corea, Samoa Occidental, Singapur y Tailandia.

3.9.5 Arribo, evolución y efectos de los tsunamis.

En la costa la altura de los tsunamis depende de:

a. Las características de las olas en mar abierto.
b. La batimetría
c. La pendiente del fondo marino
d. La configuración del contorno de la costa
e. La refracción
f. La reflexión
g. El atrapamiento de sus olas en las diversas formaciones fisiográficas costeras: bahías, golfos, penínsulas, islas, cabos, deltas fluviales, lagunas costeras, etc.).

La multiplicidad de los factores anteriores hace que la evaluación del comportamiento local del arribo de un tsunami sea un problema complejo y que, aun en distancias cortas, la altura máxima de sus olas varíe considerablemente a lo largo de la costa.

Actualmente el método más confiable y riguroso para evaluar y pronosticar con detalle las alturas máximas que alcanzarían las olas de un maremoto a lo largo de una franja costera (por ejemplo, una bahía) es la simulación numérica de la generación, la propagación y su arribo. En México se está efectuando este trabajo para los puertos ubicados en la costa del Pacífico, como es el caso del puerto de Manzanillo.

Al llegar el tsunami a la costa, su incremento de altura por asomeramiento provoca retiro del agua ante el frente de la ola y grandes extensiones del fondo marino quedan al descubierto (secas). Es un aviso de que pocos minutos después llegará una ola a gran velocidad.

En bahías semicerradas (con forma semejante a una herradura) las olas del tsunami experimentan en el interior reflexiones múltiples sucesivas en las costas opuestas, amplificándose su oscilación y la altura con que invaden las costas. Este fenómeno se denomina amplificación resonante por formación de ondas estacionarias; se genera en olas de tsunami cuya longitud sea igual o múltiplo de las dimensiones horizontales (longitud y anchura) de la bahía. Es semejante al derrame que en un plato de sopa o en una taza de café sucede cuando el líquido se excita por oscilación.

Por análisis de los registros oceanográficos, se ha inferido la ocurrencia de amplificación resonante de olas de tsunamis en bahías semicerradas, como es el caso de Manzanillo. Debido a este fenómeno, al arribo de los maremotos provenientes de Chile en 1960 y de Alaska en 1964, las alturas máximas de ola registradas en el mareógrafo de Ensenada, B.C., fueron aproximadamente el triple de las ocurridas en la costa abierta de la vecina localidad de La Jolla, California (USA), y mayores a las de otros puertos mexicanos.

3.9.6 Sistemas de Alerta.

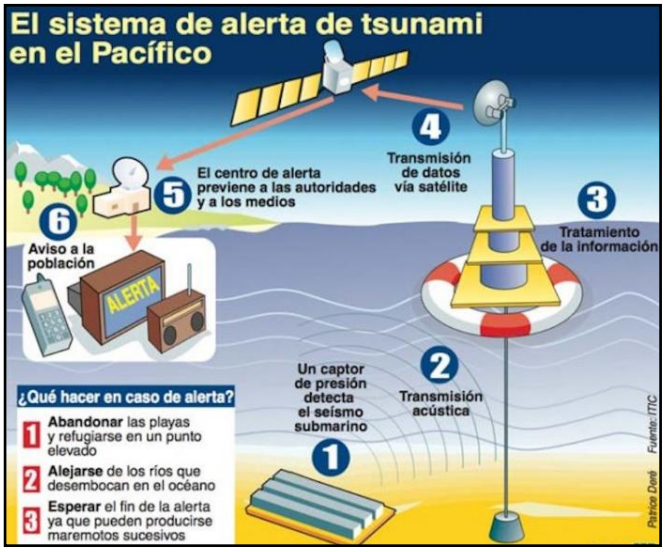
El objetivo operacional del Centro de Alerta de Tsunamis en el Pacífico (PTWC, por sus siglas en inglés) es detectar y ubicar los terremotos ocurridos en la Región del Pacífico, determinar si ellos han generado Tsunami y difundir mensajes de alerta proporcionando información en forma oportuna y efectiva. Es un programa internacional que requiere de la participación de los observatorios sismológicos y mareográficos; entidades responsables de comunicaciones y de difusión (Municipios, Defensa Civil, Ministerios, etc.) operadas en su mayor parte por las naciones localizadas alrededor del Océano Pacífico. Estas naciones participantes están organizadas bajo la Comisión Oceanográfica Intergubernamental (COI) dentro del Grupo Intergubernamental de Coordinación para el Sistema de Alarma de Tsunami del Pacífico (GIC/ITSU).

Al ocurrir un sismo de magnitud superior a 6.5 en el Océano Pacífico, el PTWC determina su epicentro, la potencialidad de que genere un tsunami, los posibles tiempos de arribo a localidades costeras vecinas, y emite un mensaje de observación. La primera confirmación proviene de las estaciones oceanográficas cercanas a la zona del epicentro. Al recibirla, el PTWC envía un mensaje de alerta con datos de altura máxima de las olas y de tiempos de arribo a otras localidades, cercanas y lejanas, ver Figura 3.46. Esta información se actualiza con mensajes de alerta subsiguientes, a medida que se monitorea el avance de las olas y su arribo a nuevas localidades, o en caso contrario, se emite un mensaje de cancelación.

3.9.6.1 Sistemas de Alerta en México.

En México, el encargado de recibir, evaluar y difundir mensajes e información provenientes del centro de operaciones en Hawái es el Centro de Alertas de Tsunamis (CAT), quien además se encarga de:

Figura 3.46 Ejemplo del Envío de Señal Desde el Mar**.**



Fuente: https://www.nauticalnewstoday.com

- Difundir información oportuna sobre la generación de tsunamis lejanos, regionales y locales que afecten el territorio nacional, que permita salvar y reducir la pérdida de vidas y bienes.

- Mantener durante las 24 horas del día, los 365 días del año, el monitoreo y análisis de la información sísmica y del nivel del mar.

- Obtener, analizar y almacenar la información sísmica y de nivel del mar que sirva de base para la emisión de boletines de alertamiento de tsunamis.

- Vigilar y alertar sobre la ocurrencia de tsunamis generados en cualquier parte del mundo que puedan afectar las costas del territorio nacional.

- Generar y difundir boletines de alertamiento de tsunamis, tomando como base los umbrales de emisión establecidos, en función de la magnitud del sismo, en coordinación con instituciones nacionales y extranjeras.

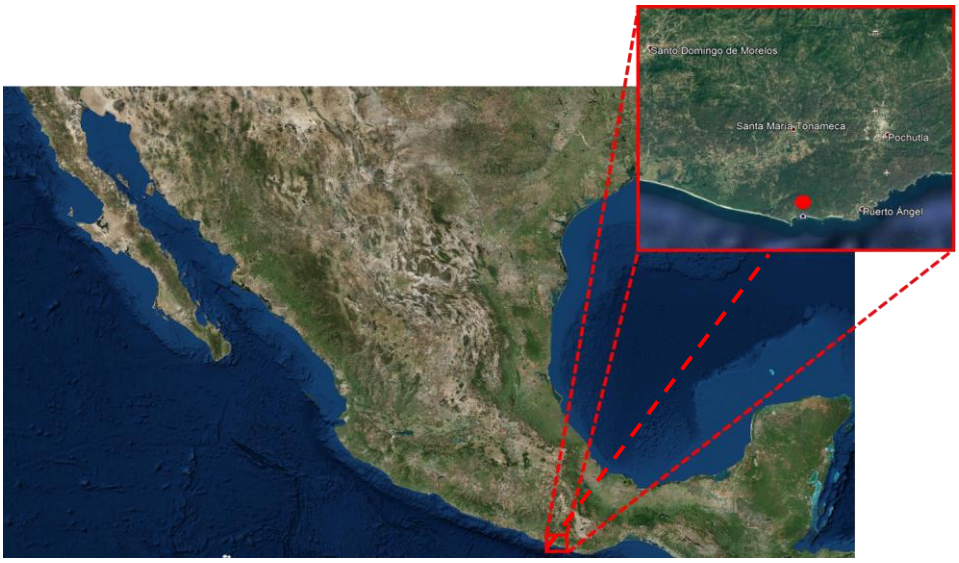
- Proponer con las instituciones académicas y/o gubernamentales el enlace técnico para llevar a cabo transferencia de tecnología, así como el desarrollo conjunto de proyectos de investigación sobre tsunamis.

- Diseñar y establecer cursos de capacitación para el personal del Centro de Alerta de Tsunamis, así como para el personal que recibe los boletines de alerta, a fin de que implemente las medidas de protección civil adecuadas.

3.9.7 Tsunamis Acontecidos en México.

En la historia reciente no se tiene conocimiento de que en México hayan ocurrido tsunamis tan destructivos como los de Chile de 1960 y del 2010; el de Alaska de 1964; el de Sumatra en 2004 y el de Japón en 2011. Sin embargo, no podemos descartar la posibilidad de que tsunamis como estos puedan ocurrir en la costa del Pacífico Mexicano. De hecho, existen evidencias de que en 1787 ocurrió un gran terremoto de magnitud 8.4 en San Sixto, Oaxaca, que generó un tsunami local sumamente destructivo (Núñez, Ortiz y Sánchez, 2008), ver Figura 3.47.

Figura 3.47 Ubicación Aproximada del Sismo Ocurrido en Oaxaca en 1787**.**



Fuente: Elaboración propia, Google Earth 2019.

La estadística de maremotos ocurridos en la costa occidental de México se dificulta porque:

- Excepto algunos lugares como Acapulco, antes del siglo XIX permaneció casi deshabilitada.

- La operación de la red de mareógrafos, lugar en el que tradicionalmente se registran los tsunamis, comenzó en 1952 y contiene vacíos notorios de datos.

Los tsunamis en la costa del Pacífico mexicano son habituales y su registro se ha dado en diferentes localidades de la Republica. Se tiene el registro realizado por CENAPRED (2005) en donde se indican el sismo que origina el tsunami, tipo de tsunami en función de la localización y la misma. La magnitud del sismo y el lugar del registro del tsunami, El valor N/D significa que no hay datos del registro.

De 1986 a 1991, en México no hubo registros; tal vez porque ninguno llegó, o por operación deficiente de los mareógrafos. En la Tabla 3.13 se muestran los tsunamis de origen local registrados en México desde 1770 hasta 1990.

En negrillas se destacan los que se han producido en la localidad de Manzanillo, en total se registran 9 tsunamis que han alcanzado las costas de Manzanillo en CENAPRED (2005), también se conoce que el tsunami de 2010 que tuvo lugar en Japón se propagó y arribó al Puerto.

De los 10 tsunamis, incluyendo este último mencionado, 7 han sido locales, 1 regional y 2 lejanos. De ellos los que mayores olas han producido en la costa de Manzanillo son los sismos locales generados en los años 1932 y 1995 (ver Figura 3.48).

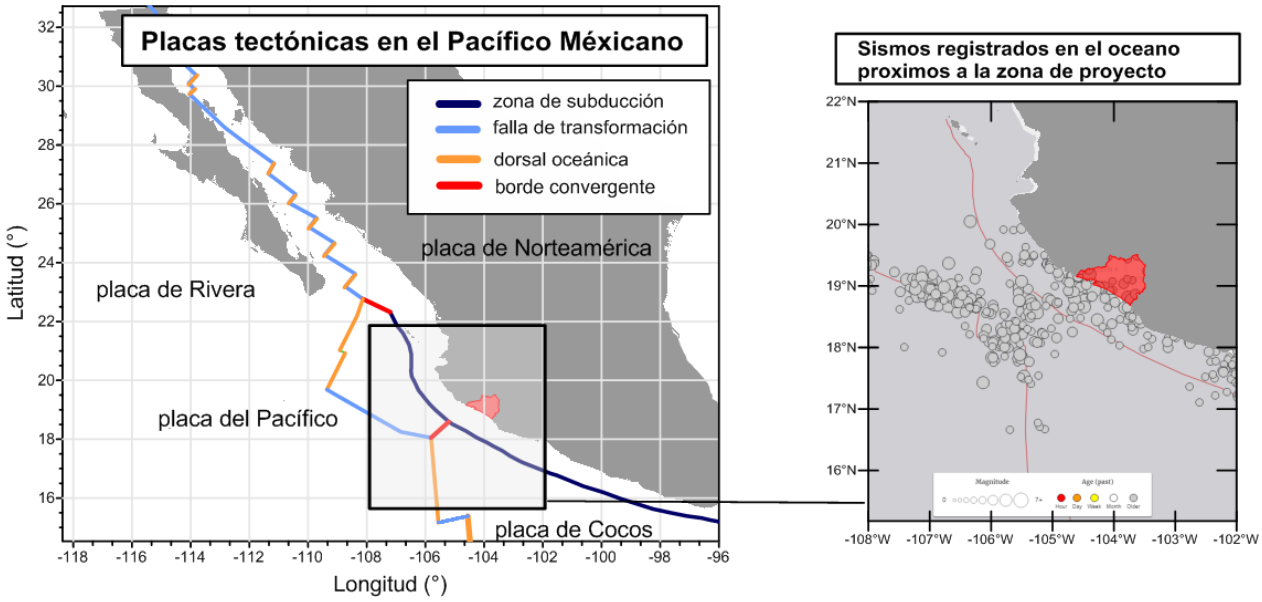
3.9.8 Vulnerabilidad de las Costas de México a los Tsunamis.

Para que un sismo genere un tsunami es necesario que ocurra una zona de hundimiento de borde de placas tectónicas; es decir: que la falla tenga movimiento vertical y no sea solamente de desgarre, con movimiento lateral. En la costa del Pacífico de México, esta condición permite diferenciar 2 zonas:

- Al norte de la Placa Rivera, donde la Placa del Pacífico se desliza hacia el norte con respecto a la Placa de Norteamérica, a lo largo de la falla de desgarre del Golfo de California. Esto propicia que las costas de Baja California, Sonora y Sinaloa no sean fuentes de tsunamis locales, sino únicamente receptoras de los lejanos, con alturas máximas de ola esperables de 3 metros, ver Figuras 3.49 y 3.50.

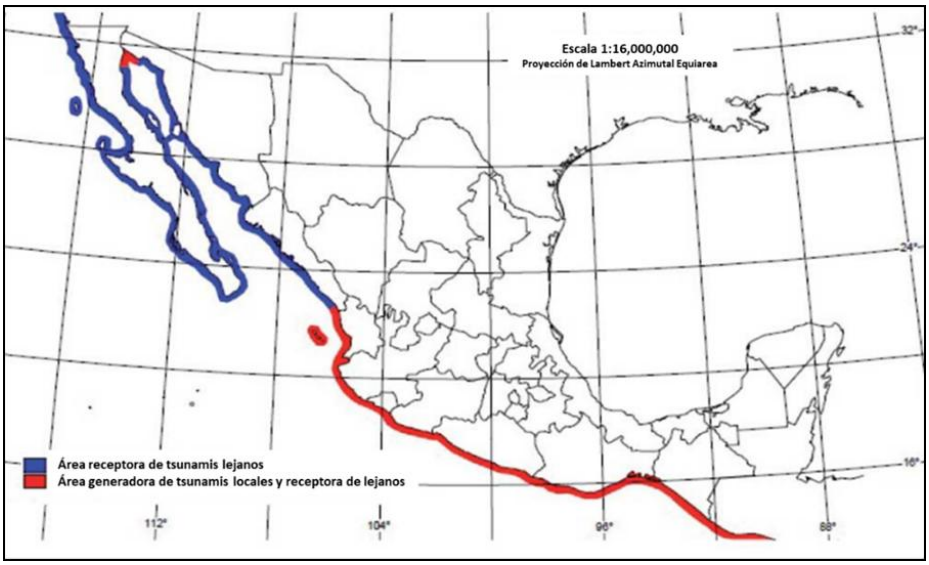
- En el Sur, la Placa de Rivera gira y la de Cocos se hunde bajo la Placa de Norteamérica a lo largo de la Fosa Mesoamericana; constituye una frontera de colisión con hundimiento, generadora de tsunamis locales, algunos de los cuales han demostrado destructividad en las costas de Nayarit, Jalisco, Colima, Michoacán, Guerrero, Oaxaca y Chiapas, con alturas de 10 metros. Esta zona también es receptora de tsunamis lejanos y regionales, con alturas esperables menores, ver Figuras 3.49 y 3.50.

Figura 3.49 Tectónica de placas en México**.**



Fuente: https://earthquake.usgs.gov/earthquakes/map/.

Figura 3.50 Vulnerabilidad de Tsunamis en México**.**



Fuente: https://digaohm.semar.gob.mx/

La zona de proyecto se ubica en lo que se denomina el Bloque tectónico de Jalisco. La ubicación de las placas tectónicas que lo conforman se observa en la Figura 4.6. También se presentan los sismos registrados hasta la fecha con magnitud superior a 6.5.

La dinámica del bloque está relacionada con la placa de Rivera. En este bloque se ubican los límites de las placas oceánicas: Cocos, Rivera y la placa del Pacífico. El movimiento relativo de la placa Rivera respecto a Norte América controlan de alguna manera el movimiento del bloque. La velocidad media de su movimiento en los 3 últimos millones de años es de 20 mm/año en el SE y va disminuyendo hacia el NW.

La geometría de la placa de subducción de las placas Cocos y Rivera es muy relevante en la zona en la tectónica regional, ya que controla el grado de acoplamiento o transmisión de esfuerzos tectónicas entre las placas. La placa de Cocos tiene una inclinación de 20° en Oaxaca (Suarez et al. 1992) con mayor inclinación al NW.

3.9.9 Tsunamis Ocurridos en Manzanillo.

Por su ubicación geográfica, el municipio de Manzanillo se encuentra sobre una de las zonas de mayor incidencia de fenómenos perturbadores de origen natural tanto geológicos como hidrometeorológicos, por lo tanto, está catalogado como un municipio de muy alto riesgo para este tipo de fenómenos dentro de la identificación de SEDESOL en el Programa de Riesgos en Asentamientos Humanos (PRAH) 2012.

A esta situación se suman los niveles de riesgo debidos a la poca planeación que históricamente se han presentado en el uso del suelo dentro del contexto urbano y el crecimiento de algunas áreas urbanas sobre suelos no aptos para los asentamientos humanos, incrementando así, el factor de riesgo y vulnerabilidad ante la presencia de fenómenos que pueden generar daños severos que incluyen: la pérdida de vidas humanas, cuantiosos daños a los bienes de la población, la infraestructura pública y privada, y en general a la economía en su conjunto.

Manzanillo se localiza sobre la zona generadora de tsunamis locales de origen sísmico (Muy cercanos de 0 a 100 Km de la costa) y tiempo de desplazamiento menor a una hora de arribo a la zona costera, y regionales (De 100 a 1,000 Km) de una a pocas horas de desplazamiento de arribo a la costa, y receptora de lejanos del Pacífico (Mayores a 1,000 Km), tiempo promedio de aproximadamente 12 horas en arribar a la costa.

Históricamente el municipio ha sido receptor de estas tres categorías de fenómenos, por lo cual, el nivel de peligro es muy alto, pues la cercanía a la zona de subducción y al desplazamiento de las placas de Rivera y Cocos con relación a la de Norteamérica, que es una zona donde se pueden generar desplazamientos verticales de importancia, generan sismos de gran magnitud, ver Tablas 3.14, 3.15 y 3.16. Otro factor detonante de este tipo de sismos, son las zonas de fracturas de Tamayo y de Rivera junto con el Dorsal del Pacifico.

3.9.10 Posibles Escenarios para Futuros Tsunamis en Manzanillo.

Los escenarios ante un tsunami en la zona de estudio están relacionados, por un lado, a la densidad de la propia población originaria del municipio y que habita en las diversas áreas susceptibles al impacto de tsunamis y, por otro lado, a la ubicación de zonas estratégicas susceptibles de gran importancia, así como la zona portuaria, por donde ingresan y salen gran cantidad de productos y mercancías para el comercio y la industria nacional e internacional.

Los factores topográficos, tales como la configuración costera (la línea de costa y la topografía del interior), así como la topografía del lecho marino, tienen gran influencia en los daños causados por un tsunami. Por ejemplo, si una bahía tiene forma de V, la concentración de la energía del tsunami tiende a amplificarse y el nivel de agua en toda la bahía tiende a ser más alto.

Una vez que el tsunami ha abierto una brecha en las defensas naturales o las construidas por el hombre, el área de inundación aumentará en las tierras bajas y llanas, que se encuentran detrás de la línea de costa. Así, aun los acantilados de fácil acceso y las zonas altas, que normalmente servirían como sitios útiles de evacuación durante una emergencia de tsunami, pueden ser difíciles de alcanzar si el terreno llano o las colinas bajas se encuentran inmediatamente detrás de la línea costera. Por consiguiente, las rutas de escape no deben seguir un camino paralelo a la costa.

Tabla 3.14 Eventos sísmicos registrados en la zona de proyecto de magnitud superior a 6.5.

De acuerdo con el análisis de la información disponible, es posible en la zona se presenten dos posibles escenarios: tsunami con una altura máxima de ola de 2 metros, siendo esta la más común, y un tsunami con una altura máxima de ola de 10 metros.

Figura 3.51 Zona de Inundación por una Ola de 10 m**.**

Fuente: http://www.atlasnacionalderiesgos.gob.mx/

3.9.10.1 Análisis para una Ola con Altura de 10 metros.

Se han realizado simulaciones numéricas de generación, propagación y arribo de tsunamis para varios puertos, zonas turísticas y comunidades costeras del Pacífico de México y como resultado de este trabajo se elaboraron los mapas de inundación. Para la ubicación del proyecto en cuestión, es posible encontrar dichos mapas en el Atlas Nacional de Riesgos de la República Mexicana (Diagnóstico de Peligros e Identificación de Riesgos de Desastres en México) editado por el CENAPRED.

Gracias al Atlas Nacional de Riesgos, fue posible obtener la imagen de la mancha de inundación para una ola generada por un Tsunami y con una altura de 10 metros. Es posible observar el alcance que dicha ola tendría en la laguna de Cuyutlán y en zonas aledañas a ésta.

De acuerdo con el modelo de inundación del CENAPRED, la zona de proyecto se encuentra comprometida de presentarse un tsunami con una altura de 10 m. Dada la magnitud de la inundación si se desea preparar la infraestructura para tal evento, el monto de inversión se incrementaría dejando fuera de todo contexto el desarrollo de esta, ya que no solo se trata del muelle y obras asociadas, si no, a toda la terminal.

En consecuencia, lo más adecuado es el preparar un plan de emergencia con los elementos básicos de preparación que comprenden la planificación anticipada y el establecimiento de áreas de evacuación, planteamiento de las rutas de evacuación, los sistemas de comunicación y la rápida divulgación de información precisa ya que cuando se genera un tsunami local, hay poco o nada de tiempo de alerta antes de que el mismo azote las costas.

La preparación ante la eventualidad de un tsunami constituye sólo parte de un plan integral que abarca un amplio abanico de potenciales daños locales, incluidos aquellos causados por terremotos, vientos y lluvias, tormentas intensas.

ÍNDICE DE TABLAS

Tabla 4.1 Participación Promedio de las Terminales de Contenedores del Puerto de Manzanillo – Periodo de Referencia 2016–2025 en el Manejo total de TEU's. 27

Tabla 5.1 Comparación estructural de escenarios. 52

1.0 INTRODUCCIÓN

El crecimiento del Puerto de Manzanillo no puede analizarse de forma aislada del contexto del comercio marítimo global, caracterizado por una creciente concentración de carga, volatilidad en los fletes, reconfiguración de rutas estratégicas y transición energética del transporte marítimo. En este escenario, la ampliación hacia la Laguna de Cuyutlán responde tanto a presiones internas de capacidad como a oportunidades estructurales derivadas de la evolución de las cadenas globales de suministro.

Manzanillo se ha consolidado como el principal puerto contenerizado de México y uno de los nodos más dinámicos del Pacífico latinoamericano. Su papel en la conexión Asia–México y su articulación con los corredores industriales del centro y occidente del país lo posicionan como infraestructura estratégica para la competitividad nacional.

El presente Estudio de Mercado tiene como propósito analizar la evolución histórica del manejo de carga del puerto, identificar las tendencias estructurales del comercio marítimo internacional, evaluar la dinámica regional y construir escenarios de proyección al horizonte 2050 que permitan sustentar técnicamente las decisiones de inversión asociadas a la ampliación.

2.0 OBJETIVOS.

2.1 Objetivo Principal.

El objetivo principal de los servicios descritos en el presente documento es:

- Analizar el entorno comercial, logístico y competitivo del Puerto de Manzanillo, con el fin de sustentar técnicamente la ampliación hacia la Laguna de Cuyutlán y definir escenarios de crecimiento consistentes con las tendencias del comercio marítimo global y nacional.

2.2 Objetivos Particulares.

Los objetivos particulares de los servicios descritos en el presente documento son:

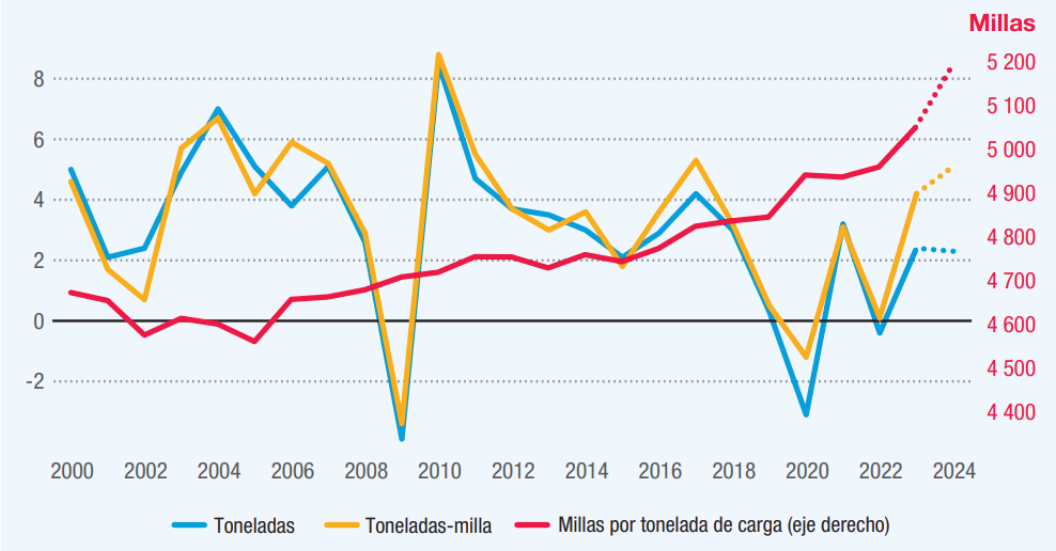
- El estudio busca examinar la evolución histórica del manejo de carga total y contenerizada del puerto, evaluar la participación de sus terminales en el sistema nacional, analizar la dinámica del comercio Asia–México y las implicaciones de la concentración naviera y los megabuques sobre la operación portuaria.

- Adicionalmente, se propone construir escenarios de proyección de carga al horizonte 2050, fundamentados en variables económicas, comerciales y operativas, así como identificar las implicaciones de infraestructura derivadas de dichos escenarios, permitiendo alinear la planeación física del puerto con una trayectoria de crecimiento sostenible y resiliente.

3.0 COMERCIO MARÍTIMO GLOBAL.

El comercio marítimo global repuntó en 2023, después de la contracción marginal del año anterior. Los volúmenes alcanzaron 12,292 millones de toneladas en 2023, lo que representó un aumento interanual del 2.4 %. El comercio en toneladas-milla[1] creció a un ritmo más rápido que el comercio en toneladas. El total estimado de toneladas-milla alcanzó 62,037 millones en 2023, lo que supone un aumento del 4.2 % respecto a 2022 (ver Figura 3.1). El crecimiento se debió a la recuperación de la economía mundial, así como al aumento de la demanda provocado por el cambio de ruta de los buques.

Figura 3.1 Crecimiento del Comercio Marítimo.
(Variación Porcentual Interanual)



Nota: Las cifras relativas a 2024 son previsiones.
Fuente: Cálculos de la UNCTAD basados en Clarksons Research Shipping Intelligence Network (serie cronológica, julio de 2024).

En conjunto, la guerra en Ucrania, las perturbaciones en el mar Rojo y la reducción del nivel del agua en el canal de Panamá han provocado que el transporte marítimo y el comercio se desplacen hacia rutas más largas. Las distancias medias recorridas por tonelada de carga siguieron aumentando en 2023, parte de una tendencia que comenzó unas dos décadas antes, con distancias que pasaron de un promedio de 4.675 millas en 2000 a 5.186 millas en 2024.

[1] Una medida de los envíos marítimos ajustados a la distancia.

Según las previsiones de la UNCTAD, el comercio marítimo total crecerá un 2% en 2024, gracias a la fuerte demanda de grandes graneles como el mineral de hierro, el carbón, los cereales, el petróleo y las mercancías transportadas en contenedores. La UNCTAD también prevé que el comercio en contenedores repunte un 3.5 %, después del crecimiento del 0.3 % en 2023. El crecimiento previsto se ve respaldado por las tendencias de la economía mundial, cierta relajación de los vientos económicos en contra, como la inflación, y un aumento moderado de las exportaciones de una serie de proveedores de gas natural licuado, entre ellos la Federación de Rusia y los Estados Unidos de América.

Más allá de 2024, la UNCTAD espera que el comercio marítimo aumente en un promedio anual del 2.4 % entre 2025 y 2029, mientras que el comercio en contenedores se prevé que aumente un 2.7 %. Este crecimiento se verá además respaldado por los avances tecnológicos, la transición a energías más limpias y el desarrollo de las infraestructuras. El crecimiento previsto a mediano plazo dependerá de la evolución de los riesgos a la baja. Entre ellos figuran la guerra en Ucrania, el aumento de las tensiones geopolíticas y las incertidumbres económicas actuales.

En el lado positivo, se prevé que continúe la recuperación del comercio mundial de mercancías, impulsada por las exportaciones de las principales economías asiáticas, especialmente en el sector tecnológico. Sectores como la energía verde y los productos relacionados con la inteligencia artificial están en expansión, al tiempo que apoyan el crecimiento del comercio. Las posibles bajadas de los tipos de interés en los Estados Unidos y la depreciación del dólar podrían aumentar la competitividad de las exportaciones estadounidenses, mientras que una moderación gradual de la inflación mundial y la mejora de las previsiones económicas podrían contribuir a un entorno más estable.

Es necesario vigilar la evolución de la relación entre la producción económica mundial y el comercio marítimo. En 2023 los volúmenes de comercio marítimo crecieron a un ritmo más lento que el producto interno bruto (PIB), tendencia diferente a la observada desde 2006 (Ver Figura 3.2). En esta relación influyen factores tanto estructurales como cíclicos, lo que plantea la cuestión de si podría producirse una disociación entre el comercio marítimo y el PIB.

En 2010 se observó por primera vez un cambio en la relación entre el comercio de mercancías y el PIB, con un crecimiento del comercio a un ritmo relativamente más lento que el del PIB. Desde 2018 se ha hecho más evidente el debilitamiento de la relación entre el comercio marítimo y el PIB. También influyen las presiones inflacionistas (que afectaron negativamente el consumo de bienes intensivos en comercio), la pandemia de enfermedad por coronavirus (COVID-19), las recientes perturbaciones de las cadenas mundiales de suministro y un ritmo más lento de globalización del comercio de bienes en comparación con el de servicios. La agenda climática también está impulsando una reducción de las industrias intensivas en transporte marítimo, como las de combustibles fósiles. El creciente proteccionismo comercial y la mayor localización de las cadenas de suministro podrían limitar el crecimiento del comercio marítimo. Sin embargo, algunas estrategias de reducción de riesgos en la cadena de suministro podrían implicar distancias más

largas, mientras que el aumento del comercio de bienes (vinculado a la transición hacia una energía más limpia) podría ser un factor compensatorio.

Figura 3.2 El Comercio Marítimo Internacional y el Producto Interno Bruto Mundial.
(Variación Porcentual Interanual)

Proyecciones de cifras del PIB basadas en datos de UNCTADstat y, para 2023 y 2024, en el cuadro I (crecimiento de la producción mundial, 1991-2024) de UNCTAD Trade and Development Report Update, abril de 2024.

3.1 El Sector Marítimo en América Latina y el Caribe.

El Informe del Transporte Marítimo 2024 de la UNCTAD revela los graves retos a los que se enfrenta el sector marítimo en América Latina y el Caribe. Las perturbaciones climáticas, las crisis geopolíticas comerciales han afectado significativamente a la región, con interrupciones en el Canal de Panamá que sirven como un claro ejemplo de los problemas más amplios, entre ellos los siguientes:

- Las perturbaciones climáticas afectan al comercio.

  La grave sequía de 2023 y principios de 2024 redujo el nivel de agua del Canal de Panamá, obligando a los barcos a tomar rutas más largas y costosas. Esto afectó especialmente al comercio entre América y Asia.

El cambio provocó un aumento del 31% en las distancias de navegación y una reducción de los volúmenes de carga, dejando al descubierto la vulnerabilidad del Canal de Panamá como ruta marítima vital. Aunque la mejora de la gestión del agua ayudó a mediados de 2024, los tránsitos siguieron disminuyendo en torno a un 20% en comparación con 2023. El informe de la UNCTAD pone de relieve la necesidad de infraestructuras portuarias resistentes al cambio climático en toda la región.

- Fluctuaciones de los fletes y cambios en el comercio

  Las tarifas de flete en toda la región fluctuaron a lo largo de 2023. Las tarifas en las rutas de Europa a Sudamérica cayeron un 36%, mientras que las rutas de África a Sudamérica experimentaron un aumento del 20%. Esta volatilidad se ha visto impulsada por los cambios geopolíticos, como la decisión de Egipto de abastecerse de grano en Brasil y Estados Unidos en lugar de Ucrania.

  Los Pequeños Estados Insulares en Desarrollo (PEID[2]) se enfrentan a retos adicionales, con un descenso del 9% en la conectividad marítima durante la última década, lo que se traduce en mayores costos y menor competitividad. Aunque Trinidad y Tobago es un centro neurálgico, los puertos más pequeños se enfrentan a ineficiencias que aumentan aún más los costos. Si no se toman medidas, estas deficiencias de conectividad agravarán las desigualdades comerciales.

- Los puertos del Caribe bajo presión

  Los puertos del Caribe se enfrentan a crecientes retos operativos. Las tasas de manipulación portuaria son entre dos y tres veces más elevadas que en puertos similares de todo el mundo, lo que se ve agravado por problemas relativos a procesos, gestión e infraestructuras. La competencia entre cruceros y buques de carga aumenta la tensión, limitando aún más la eficiencia del comercio.

  Para los PEID, cuyas economías dependen en gran medida del transporte marítimo, estas ineficiencias suponen un grave problema de desarrollo. El desequilibrio en los flujos comerciales, en los que los buques entrantes llegan completamente cargados y salen vacíos, agrava el problema, disparando los costes y reduciendo la viabilidad de los servicios marítimos.

[2] Son un grupo de países insulares de baja altitud que enfrentan vulnerabilidades sociales, económicas y ambientales, siendo los países más vulnerables y marginados del planeta. Son particularmente vulnerables al cambio climático, las catástrofes naturales y la distancia a los mercados mundiales. Muchos de ellos han asumido compromisos políticos para lograr un futuro con cero emisiones netas de carbono.

En resumen, el transporte marítimo entre América Latina y el Caribe se debate entre crisis geopolíticas y climáticas.

Por lo tanto, es necesario invertir en infraestructuras portuarias, desarrollo de capacidades y resiliencia climática para hacer frente a los retos relacionados con las interrupciones de la cadena de suministro y la conectividad marítima.

3.2 Conexión Asia – México.

Manzanillo ha experimentado un crecimiento en los últimos años, en gran parte generado por sectores como la minería en la región. Sin embargo, la actividad que más atención está atrayendo en la actualidad es el creciente comercio de México con China y su posicionamiento en las cadenas de suministro entre China y Estados Unidos. Esto ha dado lugar a un aumento de diversas actividades de ensamblaje que producen productos acabados para el mercado estadounidense, pero que utilizan componentes chinos.

Este comercio ha ejercido una presión considerable sobre las infraestructuras logísticas de México, tanto las portuarias como las que comunican con el resto de la economía mexicana y la frontera con Estados Unidos. Este desarrollo será esencial para el éxito de Manzanillo.

Aunque actualmente se presta atención a las implicaciones para México de la política arancelaria de la actual administración estadounidense, el desarrollo de grandes puertos en México con buen acceso al mercado estadounidense tendría una importancia considerable para el sector del transporte marítimo norteamericano en general.

En los dos últimos años, los importadores norteamericanos han tenido que hacer frente a amenazas de huelga en los puertos de la costa oeste y este de Estados Unidos. y a la restricción de la capacidad del Canal de Panamá. Un puerto grande y capaz en la costa mexicana podría ser una alternativa a estas rutas si puede ofrecer las capacidades terrestres necesarias.

3.3 El Transporte Marítimo y el Comercio Globalizado.

El comercio marítimo ha resultado muy afectado por la nueva oleada de perturbaciones en el mar Rojo, el canal de Suez y el canal de Panamá, ver Figura 3.3. Estas perturbaciones han afectado el número de tránsitos diarios de buques, las rutas marítimas y las distancias recorridas por los buques y la carga. Los factores del cambio climático, los conflictos y las tensiones geopolíticas plantean algunos de los riesgos más importantes que enfrenta actualmente el comercio marítimo mundial. Estos factores han puesto de manifiesto la vulnerabilidad de los puntos de estrangulamiento marítimos internacionales y siguen amenazando la fiabilidad de estas rutas cruciales, al tiempo que ejercen presión sobre las cadenas mundiales de suministro.

Figura 3.3 Perturbaciones en el Comercio Marítimo Internacional.

Fuente: www.20minutos.es.

Los puntos de estrangulamiento marítimos son puntos críticos a lo largo de las rutas de transporte. Facilitan el paso de importantes volúmenes comerciales y conectan el mundo. Debido a la escasez de rutas alternativas, las perturbaciones en los puntos de estrangulamiento repercuten negativamente en las cadenas de suministro y provocan consecuencias sistémicas que afectan la seguridad alimentaria, el suministro energético y la economía global.

Las perturbaciones de las rutas marítimas y los puntos de estrangulamiento también provocan cambios en la configuración de las redes y patrones comerciales. Por ejemplo, la guerra en Ucrania y la limitación del transporte marítimo en el mar Negro han llevado a Egipto a abastecerse de cereales en el Brasil o los Estados Unidos en lugar de en Ucrania, y los envíos de petróleo de la Federación de Rusia se han dirigido a China y la India en lugar de a Europa.

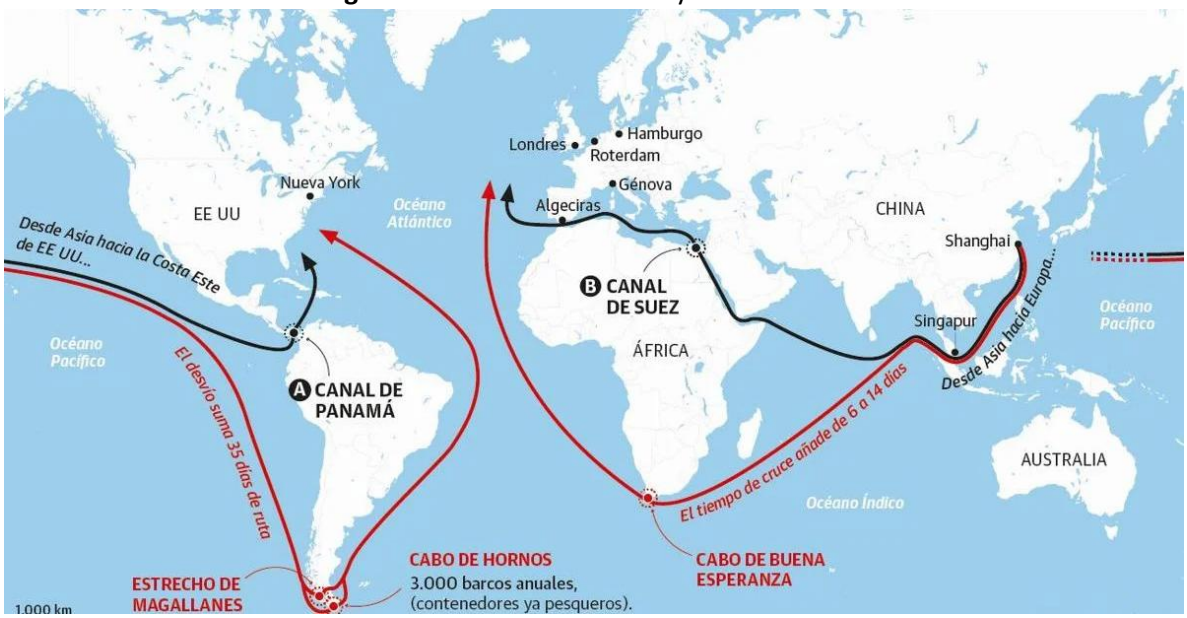
Desde 2023 los Estrechos Turcos han sufrido perturbaciones debidas a las tensiones geopolíticas, el aumento del tráfico marítimo, problemas ambientales y retos relacionados con las infraestructuras. En septiembre de 2023, Türkiye puso en marcha una normativa que incluye normas ambientales y protocolos de seguridad reforzados, y se han producido retrasos y congestiones en el período de adaptación a esta normativa.

El canal de Suez y el canal de Panamá sufrieron nuevas perturbaciones en 2023 y 2024 debido a las tensiones geopolíticas y a la reducción del nivel del agua, respectivamente. Mientras

tanto, el conflicto actual en Oriente Medio ha aumentado el riesgo de perturbaciones en el estrecho de Ormuz, mientras que la piratería sigue afectando el estrecho de Malaca.

Desde finales de noviembre de 2023, los ataques a buques en el mar Rojo han mermado la navegación en el estrecho de Bab el-Mandeb y el canal de Suez, obligando a las compañías navieras a desviarse por el cabo de Buena Esperanza. Al mismo tiempo, el canal de Panamá ha reducido los tránsitos diarios de buques debido a la sequía provocada por el cambio climático, ver Figura 3.4. Alrededor del 10 % del comercio marítimo mundial en volumen y del 22 % del comercio en contenedores cruzan anualmente el canal de Suez. El canal de Panamá facilita aproximadamente el 3 % del volumen del comercio marítimo mundial, ver Figura 3.5.

Figura 3.4 Canal de Panamá y Canal de Suez.

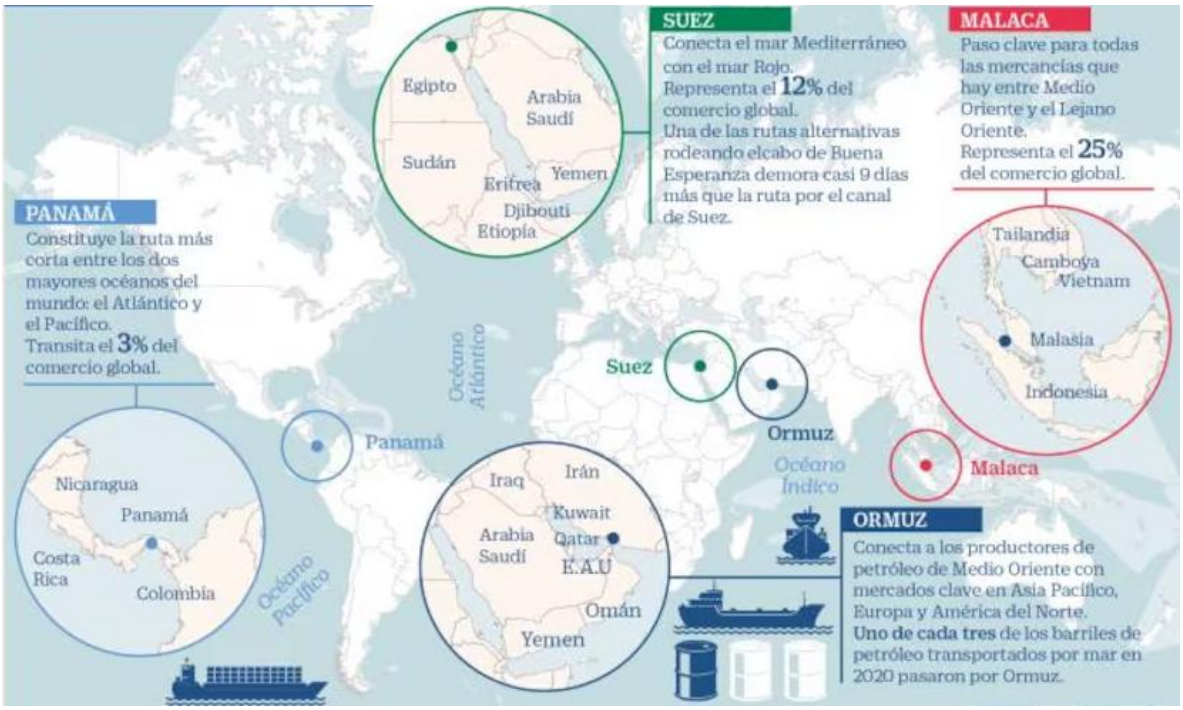


Fuente: www. cincodias.elpais.com.

En junio de 2024, los tránsitos por el canal de Panamá y el canal de Suez se habían reducido en más de la mitad en comparación con los máximos alcanzados en diciembre de 2021 y mayo de 2023 (ver Figura 3.6).

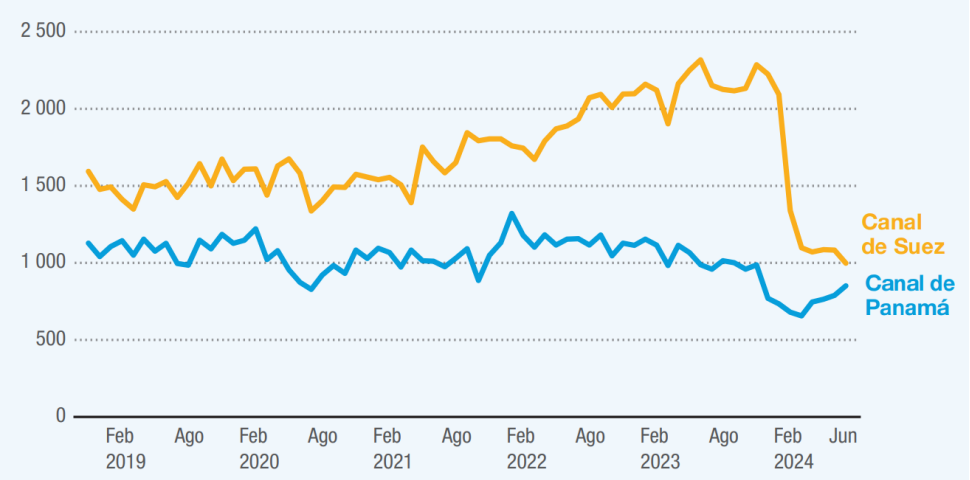
La mayor parte del descenso en el canal de Suez se ha producido desde diciembre de 2023, con el inicio de las perturbaciones en el mar Rojo; los tránsitos de buques por el canal de Panamá han disminuido en los dos últimos años.

Figura 3.5 Comercio Marítimo Internacional.



Fuente: www. cincodias.elpais.com.

Figura 3.6 Canal de Panamá y Canal de Suez, Número de Tránsitos de Buques por Mes.



Fuente: Cálculos de la UNCTAD basados en Clarksons Research Shipping Intelligence Network.

El desvío de los buques alrededor de África aumenta la distancia y prolonga los tiempos de tránsito, al tiempo que incrementa la demanda mundial de buques en un 3% y la de portacontenedores en un 12 %. Esto refleja el aumento de la demanda de toneladas-milla para los buques y portacontenedores de todo el mundo en junio de 2024, en comparación con la demanda si no hubiera habido necesidad de evitar el mar Rojo y el canal de Suez.

El desvío de los buques también provoca cambios operacionales e ineficiencias del mercado, como la congestión de los puertos y el aumento de los costos. Las rutas más largas aumentan los costos de los salarios de la tripulación, el fletamento, los seguros y el combustible. El cambio de ruta de los buques también amenaza la seguridad de la gente de mar, aumenta la exposición a incidentes de piratería, genera más emisiones de gases de efecto invernadero, dificulta el cumplimiento de las normas ambientales y crea problemas de gestión de la capacidad.

En un entorno operacional muy perturbado, deben hacerse esfuerzos para que los puntos de estrangulamiento marítimos y las cadenas de suministro sean resilientes y fiables. Para ello deben intervenir todas las partes interesadas, incluidos los Gobiernos, la industria del transporte marítimo, los gestores de las infraestructuras y las autoridades que gestionan los pasos marítimos. Entre las acciones clave figuran las siguientes:

- Utilizar la tecnología, los datos, la previsión de la demanda y los sistemas de alerta temprana para mejorar la preparación y optimizar la capacidad en los puntos de estrangulamiento.

- Emprender iniciativas de colaboración entre gestores, operadores y usuarios de los puntos de estrangulamiento marítimos para gestionar los riesgos y responder a las perturbaciones.

- Ampliar y combinar los modos de transporte para reducir la dependencia de los puntos de estrangulamiento y eludir las perturbaciones.

- Mejorar las infraestructuras, incluida la capacidad portuaria, los lugares de almacenamiento, los oleoductos y las instalaciones de toma de combustible, para reducir la congestión y crear reservas que reduzcan al mínimo las situaciones de falta de combustible o los retrasos causados por las perturbaciones.

- Velar por que se reconozca el papel de los trabajadores de la cadena de suministro y por qué se les remunere adecuadamente; así se puede evitar la escasez de fuerza de trabajo en momentos críticos, que puede agravar las perturbaciones de la cadena de suministro.

- Evitar la dependencia de una única fuente de insumos diversificando el abastecimiento y los lugares de fabricación o las fuentes y tipos de combustible.

- Aumentar los niveles de existencias para mejorar la capacidad de absorción de las perturbaciones en la cadena de suministro.

- Diversificar las rutas marítimas para evitar la dependencia excesiva de un número limitado de puertos principales; elaborar planes de contingencia que prevean el uso de rutas y puertos alternativos.

- Aumentar la cooperación entre los actores de la cadena de suministro marítima para optimizar la eficiencia de la cadena de suministro, reducir los tiempos de tránsito y disminuir los costos de transporte.

- Mejorar la colaboración internacional.

3.3.1 Los Fletes de Transporte de Contenedores.

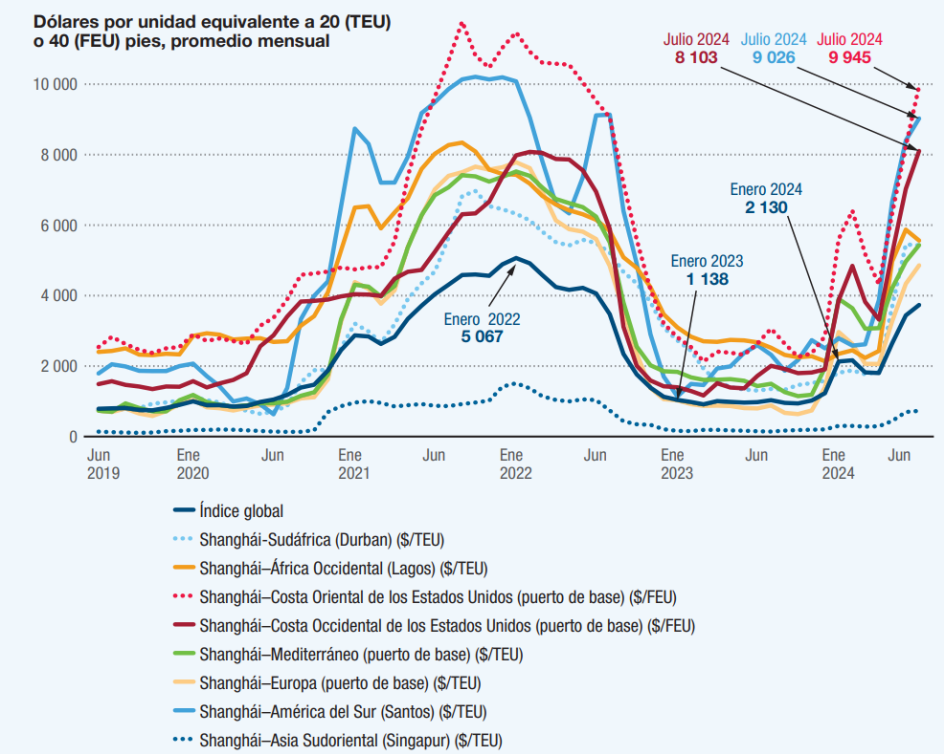
En 2023 los fletes de transporte marítimo de contenedores se estabilizaron tras los excepcionales máximos alcanzados en 2021 y 2022. El Índice de Fletes de Contenedores de Shanghái, principal indicador de las tarifas al contado del transporte de contenedores desde Shanghái (China) a varios puertos importantes de todo el mundo, se mantuvo relativamente estable en 2023, con un promedio de alrededor de 1,000 puntos (ver Figura 3.7). Esta cifra contrasta con el pico de unos 5,067 puntos alcanzado en enero de 2022, aunque el Índice volvió a repuntar a finales de 2023 debido a las perturbaciones en el mar Rojo y el canal de Suez que ampliaron las distancias medias recorridas por los buques.

En enero de 2024, el Índice se situó en un promedio de 2,130 puntos, más del doble del nivel de diciembre de 2023, aunque más del 50% por debajo del máximo alcanzado durante la pandemia de COVID-19. Los fletes volvieron a dispararse en mayo de 2024, alcanzando un promedio aproximado de 2,644 puntos, debido a las subidas generales de tarifas y a la coincidencia con la temporada alta del comercio de contenedores, junto con diversos costos adicionales, como los relacionados con el Régimen de Comercio de Derechos de Emisión de la Unión Europea, los peajes del canal de Panamá y el aumento de las primas de seguro por riesgo de guerra. Los fletes al contado se vieron afectados en la mayoría de las rutas. Las tarifas de fletamento respondieron inicialmente con lentitud a la perturbación en el mar Rojo, pero empezaron a subir a partir de enero de 2024.

Desde mediados de diciembre de 2023 hasta junio de 2024, la demanda de capacidad adicional de portacontenedores aumentó alrededor de un 12 % como consecuencia del aumento de las distancias debido a las perturbaciones. Además de absorber el exceso de capacidad, los desvíos provocaron un aumento de la velocidad de los buques para cumplir los plazos de entrega

(la velocidad de navegación aumentó aproximadamente un 25%, de 16 a 20 nudos) y la triplicación de la toma de combustible, lo que a su vez incrementó los fletes y los costos de transporte.

Figura 3.7 Tarifas al contado del Índice de Fletes de Contenedores de Shanghái.



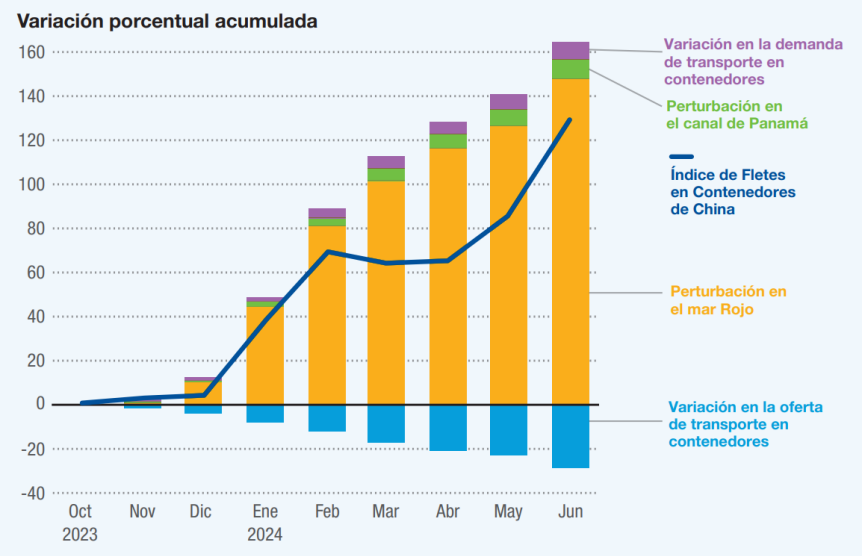
Fuente: Cálculos de la UNCTAD basados en Clarksons Research Shipping Intelligence Network.

A mediados de junio de 2024, la congestión portuaria significaba que en los buques anclados en los fondeaderos (zonas de aguas profundas, normalmente frente a las costas) esperaban 2.5 millones de unidades equivalentes a 20 pies (TEU). Esa cifra representaba el 8.4% de la capacidad mundial y también contribuyó al aumento de los fletes.

Al principio de la perturbación en el mar Rojo había suficiente capacidad de contenedores en el mercado para manejar el tonelaje adicional necesario para desviarse por el cabo de Buena Esperanza. Sin embargo, cualquier otra perturbación podría afectar gravemente las cadenas de suministro y provocar un aumento adicional de los fletes. El análisis de la UNCTAD muestra que, entre octubre de 2023 y junio de 2024, las perturbaciones en el mar Rojo y el canal de Suez tuvieron un mayor impacto en el Índice de Fletes en Contenedores de China, indicador clave de los

fletes del transporte marítimo de contenedores. Esta perturbación contribuyó en 148 puntos porcentuales al aumento acumulado del 120% del Índice (ver Figura 3.8).

Figura 3.8 Índice de Fletes en Contenedores de China y Desglose.



Nota: Variaciones acumuladas desde octubre de 2023. Desestacionalizadas. La suma de los cuatro componentes presentados no coincide totalmente con el impacto combinado porque "otros" impactos logísticos no están incluidos en la cifra

Fuente: Cálculos de la UNCTAD basados en Clarksons Research Shipping Intelligence Network y en MaritechServices Limited, Sea.

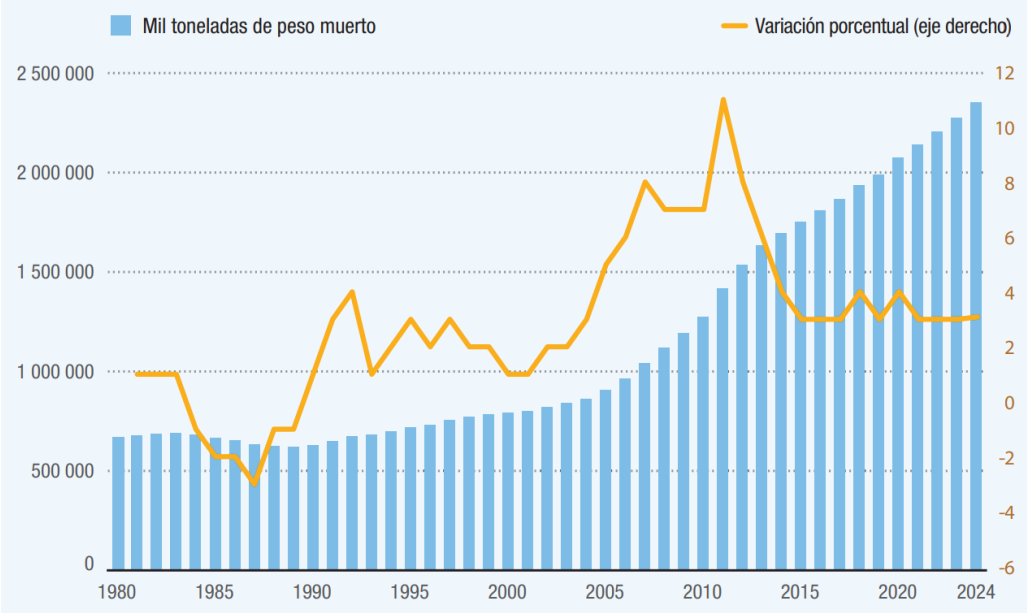
La perturbación en el canal de Panamá también contribuyó al aumento del Índice, pero en menor medida, con 9 puntos porcentuales. El impacto de estas perturbaciones en los fletes de contenedores fue compensado en parte por el aumento de la capacidad de oferta de los buques portacontenedores; cuando el desvío de los buques para evitar los puntos de estrangulamiento marítimos aumentó las distancias recorridas y la demanda de capacidad de carga, el mercado lo absorbió utilizando la capacidad adicional disponible. La capacidad adicional mitigó la subida del Índice en aproximadamente un 30%.

3.3.2 La Capacidad de la Flota Naviera.

La flota mundial creció un 3.4 % en 2023, más rápido que el comercio marítimo, pero por debajo del crecimiento medio de la flota entre 2005 y 2023 (ver Figura 3.9). La capacidad total de carga alcanzó los 2,400 millones de toneladas, impulsada por el crecimiento de los portacontenedores y los buques de transporte de gas natural licuado. Los graneleros y los

petroleros siguieron representando la mayor parte de la capacidad de la flota naviera mundial.

Figura 3.9 Tendencias en el Crecimiento Anual de la Flota Mundial.



Fuente: Cálculos de la UNCTAD basados en Clarksons Research Shipping Intelligence Network.

El cambio de ruta de los buques ha hecho que aumenten las distancias recorridas y la demanda de capacidad naviera. Esto ha contribuido a absorber el exceso de capacidad naviera imperante y a aplazar los problemas de gestión del exceso de capacidad. Sin embargo, cuando se ralentice el desvío de buques, es probable que vuelvan los problemas de exceso de capacidad.

A principios de 2024, la cartera mundial de pedidos de buques se situaba en un moderado 12 % de la capacidad activa de la flota mundial. Destacaban los pedidos de buques de doble combustible, y continuaba la adopción de tecnologías de ahorro de energía. Alrededor del 50 % del tonelaje bruto encargado podía adaptarse para el uso de combustibles alternativos y más del 14 % ya podía utilizar combustibles alternativos.

La actual incertidumbre sobre los combustibles y la tecnología del futuro, las limitaciones de capacidad de los astilleros mundiales, los elevados costos de construcción, los bajos niveles de actividad de desguace de buques y el aumento de la demanda ajustada a la distancia están retrasando las decisiones de los armadores sobre la renovación de la flota. En 2023 y el primer semestre de 2024, la actividad de desguace de buques siguió siendo baja, ya que los fletes eran

altos y se encontraban nuevas oportunidades de empleo para los buques más antiguos, derivadas del cambio de ruta de los buques.

Las tendencias de la capacidad mundial de construcción naval también influyen en las pautas de renovación de la flota. La capacidad mundial de los astilleros está actualmente desequilibrada, con algunos sobrecargados y otros infrautilizados. En 2023, China, el Japón y la República de Corea seguían dominando el mercado de la construcción naval y representaban alrededor del 95 % de la producción mundial. En 2023, por primera vez, China suministró más del 50 % del tonelaje construido.

3.4 Expectativas del Transporte Marítimo para el 2025.

El transporte marítimo es el eje central del comercio global, moviendo alrededor del 80% del comercio mundial por volumen, según datos de la UNCTAD. Esta área no solo conecta mercados y regiones, sino que también es fundamental para la logística internacional, permitiendo el intercambio eficiente de bienes y productos esenciales.

El año 2024 fue un periodo transformador para la industria marítima, marcado por un récord en volúmenes de contenedores, innovaciones tecnológicas y presiones regulatorias. Sin embargo, iniciando el 2025, el sector enfrenta desafíos importantes, como el impacto de tensiones geopolíticas, una economía global en constante cambio y la necesidad de cumplir con estrictas metas de sostenibilidad.

El 2025 se perfila como un año lleno de retos y transformaciones para la industria marítima.

Estos son los aspectos clave a considerar:

1. Sostenibilidad y regulaciones ambientales.

   La sostenibilidad será uno de los pilares fundamentales del transporte marítimo en 2025. La expansión de las regulaciones ambientales, como la normativa ETS (Emission Trading System) de la UE[3], cubrirá hasta el 70% de las emisiones de CO_2 generadas por los buques. Esto aumentará la presión sobre las navieras para acelerar sus esfuerzos hacia la descarbonización mediante el uso de combustibles alternativos (como el metanol y el amoníaco) y la electrificación parcial de sus flotas.

[3] La directiva EU ETS implica que todas las navieras deberán pagar por la cantidad de toneladas de CO2 emitidas por sus buques con el objetivo de limitar progresivamente dichas emisiones. Esta nueva normativa afectará a todos los buques de más de 5.000 GT y aplicará al 100% de las emisiones de CO2 emitidas en rutas entre puertos de la UE y al 50% en líneas con entrada o salida de la UE.

Además, los puertos también adoptarán medidas más sostenibles, utilizando fuentes de energía renovable como paneles solares y sistemas de almacenamiento energético, para reducir su huella de carbono.

2. Desaceleración en el crecimiento de volúmenes de carga.

   Tras el récord de 2024, el crecimiento de los volúmenes globales de contenedores se moderará, con una proyección de incremento del 3% en 2025. Factores como el conflicto en el Mar Rojo seguirán afectando la demanda de transporte medida en TEU's/milla, con fluctuaciones estimadas entre un crecimiento del 3% y una caída del -11%, dependiendo de la estabilidad en las operaciones del Canal de Suez.

   Por otra parte, el crecimiento de la flota mundial se ralentizará un 4.5%, y los recientes cambios en las alianzas navieras complicarán la elección de proveedores de transporte de contenedores.

3. Digitalización e innovación tecnológica.

   El 2025 será un año clave para la transformación digital del transporte marítimo. Tecnologías como el blockchain[4] y la inteligencia artificial permitirán optimizar rutas, mejorar la trazabilidad de las mercancías y reducir costos operativos.

4. Integración con el transporte terrestre.

   La coordinación entre el transporte marítimo y transporte terrestre será más estrecha en 2025. Plataformas digitales avanzadas facilitarán la gestión del flujo de mercancías desde los puertos hasta su destino final, optimizando los tiempos y reduciendo costos. También se espera una mayor inversión en infraestructura conectada, como redes ferroviarias y autopistas, para mejorar la eficiencia de la logística puerta a puerta.

5. Cambios en las dinámicas comerciales globales.

   La reconfiguración de las cadenas de suministro, impulsada por tensiones geopolíticas, dará lugar a un comercio más regionalizado. Economías emergentes en África y América Latina jugarán un papel más destacado, mientras que las tensiones en Asia y Europa seguirán redefiniendo las rutas marítimas.

[4] Blockchain, o cadena de bloques, es una base de datos digital que almacena información de forma inmutable y transparente. Se basa en la tecnología de ledger distribuido, que replica la información en computadoras individuales.

El blockchain es una innovación digital que se ha aplicado en diversos sectores, como las finanzas, la logística, la salud y el entretenimiento.

6. Tensiones laborales y huelgas.

   Las huelgas laborales continuarán siendo un desafío significativo en 2025, particularmente en las costas Este y del Golfo de Estados Unidos. Las tensiones entre los operadores portuarios y los sindicatos, respaldadas por el apoyo político, podrían causar interrupciones en las operaciones portuarias, aumentar los costos y generar retrasos en la logística internacional.

   Aunque la automatización portuaria promete mejorar la eficiencia, la resistencia sindical y las disputas prolongadas amenazan con complicar aún más las cadenas de suministro globales.

En resumen, el transporte marítimo en 2025 estará definido por la búsqueda de sostenibilidad, la adopción de tecnologías disruptivas y la necesidad de adaptarse a un panorama comercial cambiante. La lista de riesgos, desde tensiones geopolíticas hasta huelgas laborales, sigue creciendo, dejando claro que será un año desafiante para la industria.

Sin embargo, a pesar de los obstáculos, las oportunidades para innovar y mejorar la eficiencia son enormes.

3.5 Recomendaciones.

Las intensas y frecuentes perturbaciones de 2023 y 2024 han puesto de relieve el papel que desempeñan unas redes de transporte marítimo que funcionen correctamente para el comercio mundial. Al mismo tiempo, la volatilidad de los fletes, los retrasos y la congestión, los esfuerzos en curso por descarbonizar el transporte marítimo, las tensiones geopolíticas y los cambios en la política comercial siguen definiendo las perspectivas del transporte y el comercio marítimos.

El transporte marítimo, los puertos y las conexiones con el interior deben equilibrar las preocupaciones a corto plazo con las aspiraciones a largo plazo, promoviendo un transporte y una logística sostenibles y resilientes para que las cadenas mundiales de suministro estén preparadas para el futuro.

Entre las ocho acciones prioritarias recomendadas por la UNCTAD[5] en su “Informe Sobre el Transporte Marítimo 2024” figuran las siguientes:

- Promover la renovación activa de la flota y su ecologización.

[5] La UNCTAD (Conferencia de las Naciones Unidas para el Comercio y el Desarrollo) La UNCTAD es el órgano principal de la Asamblea General de las Naciones Unidas en la esfera del comercio y el desarrollo.

Aumentar la seguridad regulatoria y proporcionar marcos normativos de apoyo para agilizar la transición a tecnologías de transporte marítimo con bajas emisiones de carbono y energéticamente eficientes. Abordar las limitaciones de la construcción y el desguace navales invirtiendo en infraestructuras, servicios, tecnología y fuerzas de trabajo y fomentando las asociaciones entre Gobiernos, constructores navales, armadores, proveedores y prestamistas.

Fomentar las inversiones verdes y el financiamiento de la investigación para lograr la sostenibilidad del transporte marítimo y de las prácticas comerciales marítimas.

- Invertir en las infraestructuras y el rendimiento portuarios

  Aumentar las inversiones en las infraestructuras portuarias para reducir la congestión y mejorar la sostenibilidad y la resiliencia, incluida la resiliencia al cambio climático, y promover la eficiencia. Aprovechar la digitalización y la automatización para agilizar las operaciones y mejorar la manipulación de la carga. Fomentar las asociaciones público-privadas para colmar las lagunas en infraestructuras. Supervisar el rendimiento de los puertos adaptando los indicadores recomendados a escala mundial para los puertos, manteniendo al mismo tiempo la comparabilidad internacional.

Lo anterior nos permite identificar la necesidad de la modernización de la infraestructura portuaria, así como la modernización de la flota marítima, con miras hacia el aprovechamiento del comercio global.

4.0 ESTUDIO DE MERCADO.

4.1 Manejo de Carga Total del Puerto de Manzanillo: Situación Actual y Perfil Operativo.

El Puerto de Manzanillo se ha consolidado como el principal puerto comercial de México, con un perfil operativo claramente dominado por el tráfico contenerizado, pero con una participación relevante y estratégica de graneles minerales, graneles agrícolas, carga general y energéticos, lo que le confiere una vocación portuaria mixta de alta complejidad operativa.

De acuerdo con el Programa Maestro de Desarrollo Portuario de los Puertos de Manzanillo y Laguna de Cuyutlán 2021–2026 (PMDP), el puerto cuenta actualmente con 15 instalaciones y terminales portuarias que permiten atender ocho líneas de negocio diferenciadas, reflejando una estructura portuaria diversificada y especializada.

Esta diversificación ha sido uno de los factores que explican su resiliencia operativa frente a ciclos económicos y disrupciones del comercio marítimo.

4.1.1 Predominio del tráfico contenerizado.

El manejo de carga contenerizada constituye el eje central de la actividad portuaria en Manzanillo. El propio PMDP señala que el puerto lidera el movimiento de contenedores en México, concentrando alrededor del 68.7 % del total de TEU manejados a nivel nacional en el periodo de referencia del documento.

Esta condición posiciona a Manzanillo como el principal nodo del comercio exterior mexicano en el litoral del Pacífico.

La carga contenerizada que se moviliza a través del puerto está compuesta mayoritariamente por insumos para cadenas productivas, bienes intermedios y productos manufacturados, lo que refuerza su papel como puerto de soporte a la industria nacional. El PMDP identifica como principales mercados de destino y origen las regiones del Centro y Occidente del país, con una fuerte articulación logística hacia Ciudad de México, Estado de México, Bajío, Nuevo León y Jalisco, así como una participación relevante de movimientos de transbordo, que representan aproximadamente 32.4 % del total del movimiento contenerizado.

Desde el punto de vista operativo, el manejo de contenedores se apoya en una infraestructura portuaria madura, con muelles especializados, patios de almacenamiento, servicios intermodales y conectividad ferroviaria y carretera. No obstante, el alto volumen y la creciente concentración de operaciones asociadas a buques de gran tamaño han incrementado la presión sobre patios, accesos y corredores logísticos, configurando uno de los principales retos actuales del puerto.

4.1.2 Granel mineral y granel agrícola.

El granel mineral constituye otro componente relevante del manejo de carga en Manzanillo, particularmente en el contexto del litoral del Pacífico. El PMDP indica que este tipo de carga se asocia principalmente al transporte de minerales metálicos, con flujos de exportación e importación vinculados a la actividad minera regional y nacional.

Estos movimientos refuerzan el papel del puerto como nodo logístico para sectores primarios estratégicos.

En cuanto al granel agrícola, Manzanillo desempeña un papel clave como punto de entrada de materias primas para la agroindustria nacional, especialmente granos destinados a procesos de transformación y consumo interno. El documento señala que, solo en el año 2020, el movimiento de granel agrícola alcanzó más de 1.5 millones de toneladas, cifra que refleja la importancia de este segmento para el abasto nacional y para cadenas productivas de alimentos.

Ambos tipos de graneles implican requerimientos operativos específicos en términos de almacenamiento, control ambiental, segregación de flujos y coordinación con transporte terrestre, lo que añade complejidad al sistema portuario y exige una gestión cuidadosa del espacio y de los procesos.

4.1.3 Carga general.

La carga general mantiene una participación menor en comparación con contenedores y graneles, pero sigue siendo significativa para determinados nichos industriales. El PMDP destaca que este tipo de carga incluye principalmente productos siderúrgicos, acero de importación y mercancías con destino a la industria automotriz, particularmente en Jalisco y el centro del país.

Su manejo requiere infraestructura especializada y compatibilidad operativa con otros tráficos, especialmente en zonas del puerto con alta densidad de operaciones.

4.1.4 Energéticos y derivados del petróleo

El segmento de energéticos y derivados del petróleo tiene un peso estratégico en el perfil del puerto, aunque parte relevante de este tráfico se canaliza a través de instalaciones asociadas a PEMEX, incluyendo el manejo de hidrocarburos en el recinto portuario y en el puerto de Laguna de Cuyutlán. El PMDP señala que Manzanillo es un punto clave para la importación de combustibles, particularmente gasolinas y diésel, con una participación elevada del total nacional en determinados periodos.

Este tipo de carga introduce exigencias estrictas en materia de seguridad, gestión de riesgos y compatibilidad ambiental, y condiciona la zonificación portuaria y la planificación de futuras expansiones.

4.1.5 Síntesis del perfil actual

En su estado actual, el Puerto de Manzanillo opera como un puerto multipropósito de gran escala, con un claro liderazgo en carga contenerizada y una base diversificada de tráficos complementarios. Esta combinación explica tanto su alta relevancia estratégica como los retos operativos que enfrenta, particularmente en términos de congestión, gestión de picos operativos y coordinación logística con su hinterland.

El PMDP reconoce explícitamente que el puerto ha alcanzado un nivel de madurez en infraestructura y equipamiento, pero también identifica limitaciones físicas y operativas que justifican la expansión hacia la Laguna de Cuyutlán como mecanismo para sostener el crecimiento, mejorar la eficiencia y atender tráficos que, por dimensiones o características, no pueden ser absorbidos de manera óptima en el recinto actual.

4.2 Evolución Histórica del Manejo de Carga en el Puerto de Manzanillo (1992–2024).

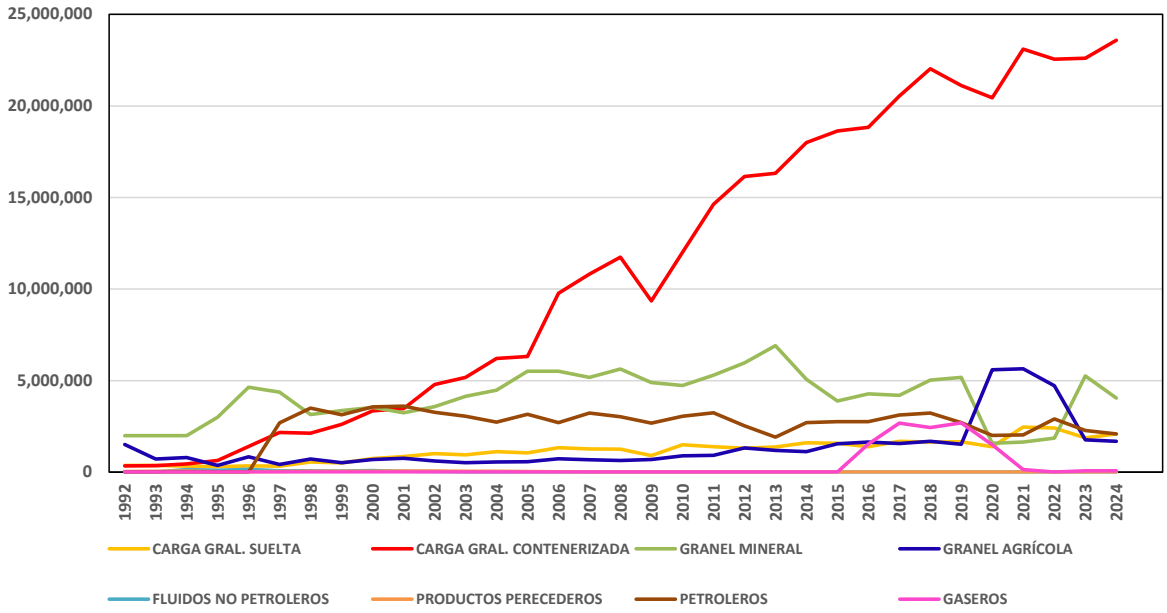
El análisis de la estadística histórica del Puerto de Manzanillo entre 1992 y 2024 permite identificar una transformación profunda del perfil portuario, tanto en términos de volumen total manejado como en la composición de los tráficos. A lo largo de este periodo, el puerto pasó de ser un puerto multipropósito con predominio de graneles y carga general, a consolidarse como el principal puerto contenerizado del país, con una estructura operativa altamente especializada y una creciente complejidad logística.

4.2.1 Evolución del volumen total de carga

En términos agregados, el manejo total de carga en Manzanillo presenta una tendencia de crecimiento sostenido de largo plazo, interrumpida únicamente por episodios coyunturales asociados a crisis económicas, disrupciones comerciales o ajustes en los mercados internacionales. Desde principios de la década de 1990, el volumen total manejado muestra una expansión significativa, reflejando tanto el crecimiento del comercio exterior mexicano como la consolidación del puerto como nodo estratégico del Pacífico.

A partir de la década de 2000, el crecimiento se acelera de forma más marcada, coincidiendo con la intensificación de los flujos comerciales con Asia y con la incorporación progresiva de infraestructura especializada para contenedores. En el periodo más reciente (2010–2024), el volumen total continúa creciendo, aunque con una mayor volatilidad interanual, lo que evidencia un entorno de mercado más incierto y sensible a factores externos.

Figura 4.1 Movimiento de Carga en el Puerto de Manzanillo (1992 – 2024).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

4.2.2 Transformación estructural: ascenso de la carga contenerizada

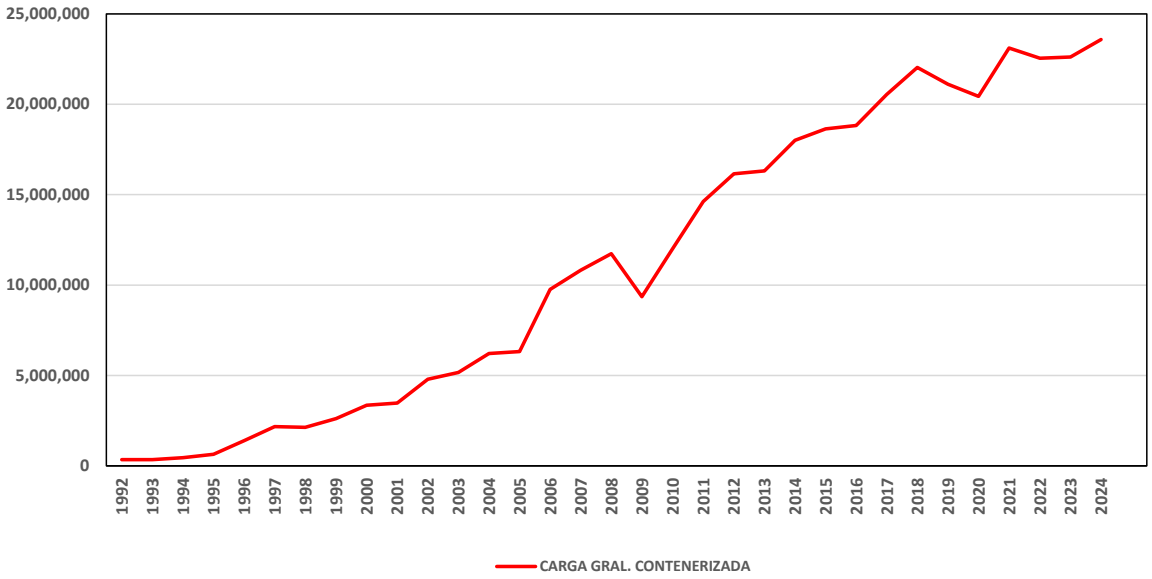
El rasgo más significativo de la evolución histórica es el crecimiento exponencial de la carga general contenerizada. Mientras que en los primeros años del periodo analizado la carga contenerizada representaba una fracción relativamente limitada del total, a partir de finales de los años noventa y, especialmente, durante la década de 2000, su participación aumenta de forma sostenida hasta convertirse en el componente dominante del manejo de carga.

Los datos históricos muestran que, desde 2010 en adelante, la carga contenerizada supera ampliamente a cualquier otro tipo de carga en términos de toneladas movilizadas, consolidando un perfil portuario claramente orientado a contenedores. Este crecimiento no ha sido lineal: se observan periodos de fuerte expansión —asociados a la entrada de nuevas rutas, mayor conectividad internacional y ampliaciones de capacidad— y fases de estabilización o ajustes, reflejo de la volatilidad del comercio marítimo global.

Esta evolución explica por qué el puerto enfrenta hoy presiones estructurales sobre patios, muelles y accesos terrestres, ya que el crecimiento del contenedor implica no solo mayores

volúmenes, sino una mayor concentración operativa y exigencias logísticas más complejas que otros tráficos.

Figura 4.2 Movimiento de Carga Contenerizada en el Puerto de Manzanillo (1992 – 2024).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

4.2.2.1 Terminales de contenedores del Puerto de Manzanillo

El Puerto de Manzanillo opera hoy con varias terminales especializadas en carga contenerizada, que en conjunto constituyen el núcleo del tráfico de contenedores del país. Estas terminales están concesionadas a operadores privados tanto nacionales como internacionales, cuentan con equipamiento moderno y servicios logísticos integrados, y se distinguen por su capacidad de atender buques de gran porte y por su conectividad con el hinterland.

a. Terminal Especializada en Contenedores I (TEC I).

La Terminal Especializada en Contenedores I (TEC I) es la instalación histórica y principal terminal pública programada para contenedores en Manzanillo, bajo la administración de ASIPONA Manzanillo. Esta terminal se caracteriza por:

- **Superficie y muelle**: Cuenta con una cesión parcial de derechos de 259,422.79 m² y un frente de muelle de 1,076 metros lineales, distribuido en posiciones de atraque Nº10, 11, 12 y 13.

- **Profundidad**: Las profundidades oscilan entre 13.0 y 13.5 metros dependiendo de la posición, permitiendo la atención de buques de mediano y gran porte.
- **Especialización**: Su programación es de uso público programado con uso preferencial para contenedores, lo que significa que atiende principalmente este tipo de carga, aunque, en situaciones puntuales, puede recibir cargas complementarias.
- **Rol operativo**: TEC I ha servido como el primer eje de atención contenerizada en Manzanillo, facilitando vinculación directa con corredores terrestres y ferroviarios y actuando como la base para el crecimiento del tráfico global de TEU's en el puerto.

Esta terminal juega un papel clave en distribuir importaciones y exportaciones del centro y occidente del país, y su capacidad física la posiciona como un punto de equilibrio entre espacios de muelle y patios de almacenamiento.

b. SSA Marine México – Terminal Especializada de Contenedores (Terminal SSA).

Operada por SSA Marine México, esta es una de las terminales contenerizadas más grandes y tecnológicamente equipadas del país, con características que la diferencian claramente:

- **Infraestructura robusta**: Incluye un muelle de 1,350 metros de longitud y una superficie de patio de 32 hectáreas dedicada a contenedores.
- **Equipamiento moderno**: Cuenta con grúas pórtico Super Post-Panamax y equipos de patio de última generación, lo que permite atender buques de gran tamaño con altos niveles de eficiencia operativa.
- **Conectividad**: Dispone de tres vías ferroviarias de 500 metros, casetas de acceso exclusivas con múltiples carriles para camiones, y facilidades de intermodalidad que reducen tiempos de despacho y de evacuación.
- **Servicios integrados**: La terminal incluye un Centro Fiscalizado Estratégico para contenedores llenos, un patio externo para contenedores vacíos de casi 10 hectáreas, y capacidades de inspección y almacenaje refrigerado.
- **Productividad**: Además de las grúas de muelle, SSA cuenta con una amplia flota de equipos de manipulación en patio y sistemas automatizados que apoyan la eficiencia de movimientos y el control de inventario.

Este operador posiciona a Manzanillo en los estándares de nodos globales gracias a su infraestructura de clase mundial, certificaciones internacionales y su enfoque en mejorar tiempos de respuesta y fiabilidad.

c. CONTECON Manzanillo S.A. de C.V. (Terminal Contecon / Terminal II)

La Terminal Especializada en Contenedores II, operada por Contecon Manzanillo (parte del grupo internacional ICTSI), es otra instalación estratégica orientada al crecimiento del tráfico contenerizado:

- **Superficie**: Aproximadamente 72.42 hectáreas, lo que le proporciona un amplio espacio para patios de contenedores, maniobras y actividades logísticas complementarias.
- **Muelles**: Opera dos posiciones de atraque, cada una con una longitud de 360 metros y calado de 15 metros, lo cual permite la atención de buques de mayor calado y tamaño.
- **Rol funcional**: Esta terminal representa un pilar para el crecimiento continuo del puerto y ha sido un receptor importante de los flujos de importación provenientes de Asia.
- **Crecimiento y movilidad**: Recientemente se ha reportado que esta terminal (junto con ampliaciones) ha superado 12 millones de TEU acumulados, con un aumento significativo de volumen en los últimos años, apoyando el crecimiento general del puerto.

La infraestructura de CONTECON está diseñada para responder tanto a las necesidades de buques de mayor eslora como a la atención eficiente de flujos intensivos de importación y exportación.

d. Hutchison Ports TIMSA (Terminal TIMSA / Instalación de Usos Múltiples II)

Hutchison Ports, operador global con presencia en múltiples países, también participa en Manzanillo con la terminal TIMSA, ubicada en áreas auxiliares pero vinculada operativamente a flujo contenerizado:

- **Operación multifuncional**: Aunque TIMSA maneja distintos tipos de mercancías, tiene un área dedicada al soporte de contenedores, ubicada frente a tramos clave de muelle (Tramo 6 Banda “B” y Tramo 7 Banda “C”).
- **Servicios y conectividad**: Esta terminal complementa la red de atención de contenedores en el puerto y ofrece servicios relacionados con programación, manejo de vacíos y atención de cargas múltiples, integrándose con corredores terrestres para facilitar la salida de TEU.
- **Flexibilidad operativa**: Además de manipulación física, soporta operaciones de planificación, despacho y soluciones logísticas que fortalecen el desempeño global del puerto.

En conjunto, estas terminales generan un ecosistema operativo dual:

- Terminales de alta productividad y tecnología (SSA) con altos niveles de automatización y capacidad de maniobra para grandes barcos y flujos intensivos de TEU.
- Terminales con potencial de expansión y volumen (CONTECON) que atienden buena parte del tráfico y permiten absorber crecimiento futuro mediante ampliaciones estratégicas.
- Terminales complementarias (TEC I, TIMSA) que facilitan la operación continua del puerto, reduciendo cuellos de botella puntuales y ofreciendo flexibilidad operativa.

Tabla 4.1 Participación Promedio de las Terminales de Contenedores del Puerto de Manzanillo – Periodo de Referencia 2016–2025 en el Manejo total de TEU's.

TERMINAL	PARTICIPACIÓN PROMEDIO EN TEU's (%)	ROL OPERATIVO DOMINANTE	OBSERVACIONES TÉCNICAS CLAVE
SSA Marine México	40–45 %	Terminal líder de volumen y productividad	Alta concentración de picos operativos; fuerte presencia de importación, exportación y transbordo; principal punto de presión sobre patios y accesos.
CONTECON Manzanillo (TEC II)	30–35 %	Segundo pilar del sistema contenerizado	Alta dependencia del hinterland; foco en importación/exportación; crecimiento sostenido ligado al mercado interno y Asia–México.
Terminal Especializada de Contenedores I (TEC I)	15–20 %	Terminal complementaria y estabilizadora	Mayor variabilidad interanual; absorbe flujos específicos y aporta flexibilidad operativa en periodos de alta demanda.
Instalaciones multipropósito (TIMSA y otras)	< 5 %	Apoyo operativo y manejo marginal	Participación reducida; función clave en manejo puntual, vacíos y descongestión táctica del sistema.
Total, Puerto de Manzanillo	**100%**	**Sistema contenerizado concentrado**	**Dos terminales concentran aproximadamente entre el 70% al 80% del total de TEU's, rasgo típico de puertos líderes, pero con alto riesgo sistémico ante congestión.**

Nota: Las participaciones presentadas corresponden a promedios estructurales estimados a partir de la estadística oficial de TEU por terminal y tipo de tráfico del periodo 2016–2024. Se utilizan rangos porcentuales para reflejar la variabilidad interanual asociada a cambios en servicios navieros, composición de tráficos y condiciones del mercado.
Fuente: Elaboración propia con datos estadísticos proporcionados por ASIPONA Manzanillo, 2026.

De esta tabla se desprenden tres conclusiones estratégicas:

a. Alta concentración operativa: El 70–80 % de los TEU del puerto se procesa en dos terminales, lo que amplifica cualquier disrupción operativa.

b. Crecimiento futuro = presión directa sobre los mismos nodos: Sin nuevas terminales, cualquier crecimiento proyectado se traduce automáticamente en mayor presión sobre SSA y CONTECON.

c. Límite estructural del modelo actual: Incluso con mejoras incrementales, el sistema actual tiene una capacidad limitada para absorber crecimiento sostenido sin pérdida de nivel de servicio.

Por otra parte, la estructura de las terminales actuales es un componente determinante de la capacidad instalada del puerto y de su productividad operativa. SSA y CONTECON constituyen los pilares tecnológicos y de volumen del manejo contenerizado. La combinación de muelles de distinta profundidad y extensión permite atender buques de variadas características, lo que es esencial ante la tendencia global de buques más grandes. Los patios, conexiones ferroviarias y servicios de inspección y almacenaje complementan la infraestructura física, condicionando directamente los flujos de salida y entrada.

Entender cada terminal en detalle permite evaluar correctamente los cuellos de botella actuales y dimensionar con mayor precisión la necesidad de expansión hacia Cuyutlán bajo un enfoque port-led, donde nuevas terminales y corrientes logísticas serán articuladas de manera coherente con la operación global del puerto.

4.2.2.2 Participación de las terminales de contenedores en el total de TEU’s del Puerto de Manzanillo.

El análisis de la estadística por terminal muestra que el manejo de contenedores en Manzanillo se distribuye de manera concentrada pero complementaria entre tres grandes operadores: SSA Marine México, CONTECON Manzanillo y la Terminal Especializada de Contenedores I (TEC I), con una participación marginal de instalaciones multipropósito en funciones de apoyo. Esta estructura explica tanto la elevada capacidad instalada del puerto como las tensiones operativas que hoy enfrenta.

a. SSA Marine México: terminal líder en volumen y productividad

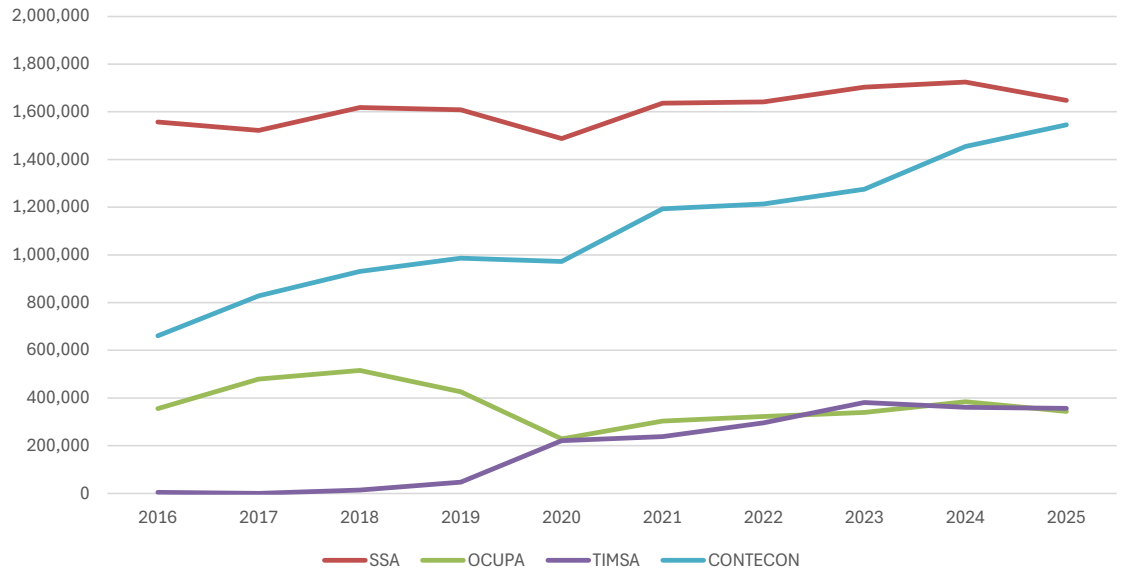
A lo largo del periodo 2016–2024, SSA Marine México se consolida como la terminal con mayor participación en el total de TEU’s del puerto, concentrando de forma consistente el mayor porcentaje del movimiento anual. En términos agregados, su participación se ubica típicamente en un rango aproximado de 40% a 45% del total de TEU’s manejados en

Manzanillo, con variaciones interanuales asociadas a cambios en servicios navieros y composición de tráficos.

Desde el punto de vista del tipo de tráfico, SSA presenta una estructura balanceada entre importación y exportación, con una participación relevante del transbordo, lo que refuerza su rol como terminal de alta productividad orientada a servicios de línea principal. Esta combinación explica por qué SSA absorbe buena parte de los picos operativos asociados a la llegada de buques de gran tamaño, concentrando volúmenes significativos en ventanas temporales reducidas.

En el contexto del sistema portuario, SSA funciona como el principal motor del volumen contenerizado, pero también como uno de los puntos donde primero se manifiestan las tensiones de patio, accesos y evacuación terrestre cuando la demanda se intensifica.

Figura 4.3 Participación de las terminales de contenedores en el total de TEU's del Puerto de Manzanillo.
(TEU's)



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

b. CONTECON Manzanillo: segundo pilar del sistema contenerizado

La Terminal Especializada en Contenedores II (CONTECON Manzanillo) se posiciona de manera consistente como el segundo operador en importancia, con una participación que oscila generalmente entre 30 y 35 % del total de TEU del puerto. Su crecimiento a lo largo del periodo analizado ha sido sostenido, en particular en los años posteriores a su consolidación operativa.

CONTECON presenta una alta concentración en tráfico de importación y exportación, con menor peso relativo del transbordo en comparación con SSA. Esta característica la vincula de manera directa con las cadenas logísticas del mercado interno mexicano, especialmente con los corredores hacia el centro y el Bajío. Desde una perspectiva operativa, esto implica una fuerte dependencia de la eficiencia de los accesos terrestres y de la capacidad del hinterland para absorber flujos crecientes.

La combinación de SSA y CONTECON explica que, en conjunto, dos terminales concentren alrededor del 70% al 80% del total de TEU’s del puerto, un rasgo típico de puertos líderes, pero que también incrementa el impacto sistémico de cualquier congestión en estas instalaciones.

c. Terminal Especializada en Contenedores I (TEC I): rol complementario y estabilizador

La TEC I, operada bajo el esquema de uso público programado, mantiene una participación menor en términos de volumen, generalmente en un rango de 15% al 20% del total de TEU’s. Su contribución, sin embargo, es estratégica desde el punto de vista del equilibrio del sistema, ya que permite absorber parte de la demanda y ofrecer flexibilidad operativa en determinados tráficos.

TEC I presenta una mayor variabilidad interanual en su participación, reflejando su papel como terminal de apoyo que atiende flujos específicos y contribuye a descongestionar el sistema en momentos de alta demanda. Su estructura de tráfico está más orientada a importación y exportación directa, con una presencia limitada de transbordo.

d. Instalaciones multipropósito y participación marginal

Otras instalaciones, como TIMSA y muelles de uso múltiple, tienen una participación marginal en el total de TEU’s, generalmente inferior al 5%, y cumplen funciones de apoyo, manejo de vacíos o atención puntual de contenedores en combinación con otros tipos de carga. Aunque su peso en el volumen total es reducido, su existencia contribuye a la flexibilidad operativa del puerto, especialmente en escenarios de alta ocupación de las terminales principales.

La distribución del total de TEU's entre las terminales de Manzanillo revela una estructura altamente concentrada, donde:

- SSA Marine México actúa como el principal generador de volumen y productividad.
- CONTECON Manzanillo funciona como segundo pilar, estrechamente vinculado al mercado interno.
- TEC I cumple un rol complementario que aporta estabilidad y capacidad de absorción adicional.

Esta configuración explica por qué las tensiones operativas del puerto no se distribuyen de manera homogénea, sino que se concentran en las terminales líderes, especialmente durante picos operativos asociados a megabuques y a ciclos de alta demanda.

La participación histórica de cada terminal permite entender que el crecimiento futuro del puerto no puede sostenerse únicamente ampliando la capacidad dentro de las terminales existentes. Incluso incrementos relativamente modestos en el total de TEU's se traducen en presiones significativas sobre SSA y CONTECON, y por arrastre sobre patios, accesos y corredores.

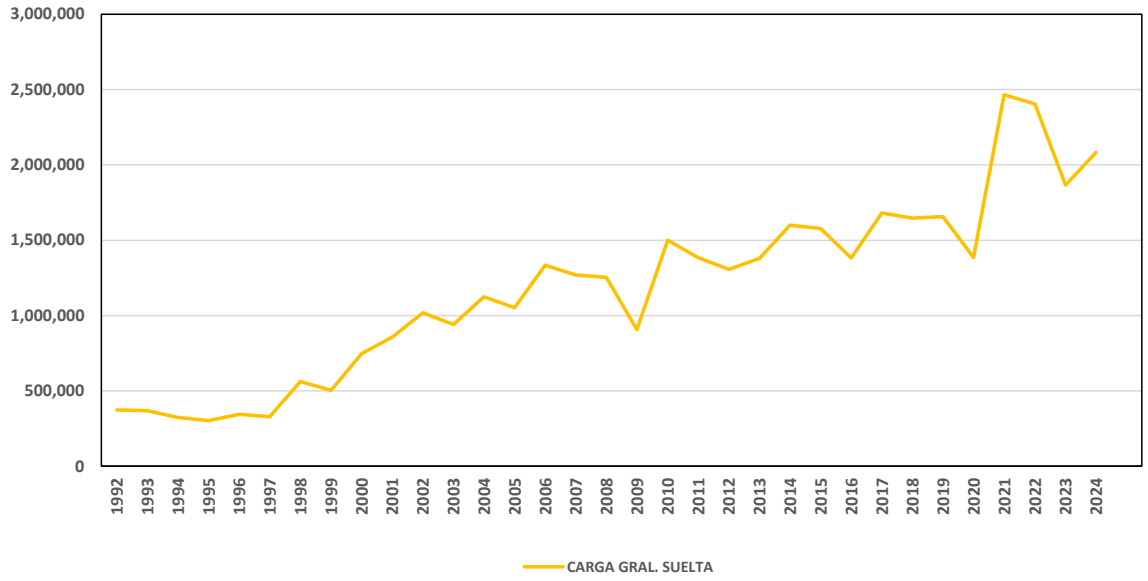
Por ello, las proyecciones de carga 2026–2050 deben leerse a la luz de esta estructura: sin nuevas terminales y sin una redistribución espacial de funciones logísticas (enfoque port-led), el crecimiento tenderá a concentrarse en los mismos nodos, reproduciendo y amplificando las tensiones actuales.

4.2.3 Carga general fraccionada: pérdida relativa de protagonismo

La carga general fraccionada muestra una tendencia opuesta. Aunque mantiene volúmenes relativamente estables en ciertos periodos, su peso relativo dentro del total disminuye de manera progresiva a lo largo del tiempo. Este comportamiento es coherente con la evolución del transporte marítimo internacional, donde la contenerización desplazó gran parte de la carga general tradicional.

En Manzanillo, la carga general fraccionada pasa de ser un componente relevante en los años noventa a ocupar un papel más marginal en la estructura actual del puerto, concentrándose en nichos específicos como productos siderúrgicos o mercancías con requerimientos particulares. Su evolución histórica refuerza la idea de que el puerto ha seguido una trayectoria de especialización, adaptándose a los cambios tecnológicos y logísticos del comercio marítimo.

Figura 4.4 Movimiento de Carga Suelta o Fraccionada en el Puerto de Manzanillo (1992 – 2024).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

4.2.4 Granel mineral: crecimiento con alta variabilidad

El granel mineral presenta una evolución caracterizada por crecimientos significativos en determinados periodos, seguidos de fases de ajuste o reducción. Esta volatilidad responde a la naturaleza cíclica de los mercados de materias primas, a la demanda de la industria minera y a factores de precio internacional.

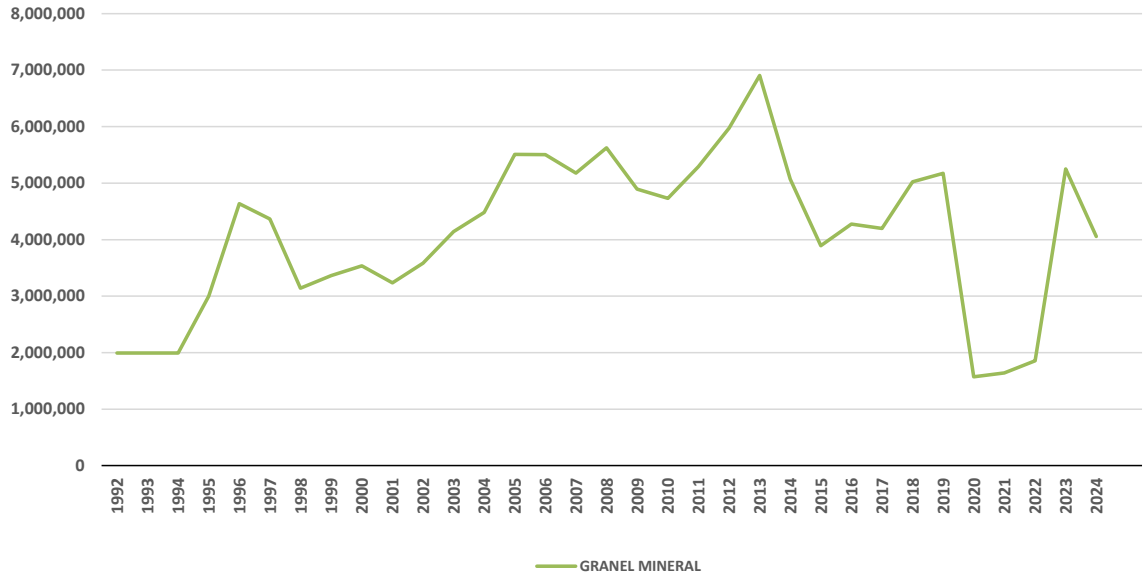
A pesar de esta variabilidad, el granel mineral mantiene una presencia estructural relevante en el puerto a lo largo de todo el periodo analizado. En varios años, los volúmenes manejados alcanzan niveles elevados, lo que confirma el papel de Manzanillo como plataforma logística para sectores extractivos y metalúrgicos, tanto en exportación como en importación.

Desde una perspectiva de planeación, esta evolución refuerza la necesidad de infraestructura especializada y segregada, capaz de absorber picos de demanda sin interferir con los tráficos contenerizados.

4.2.5 Granel agrícola: consolidación como tráfico estratégico

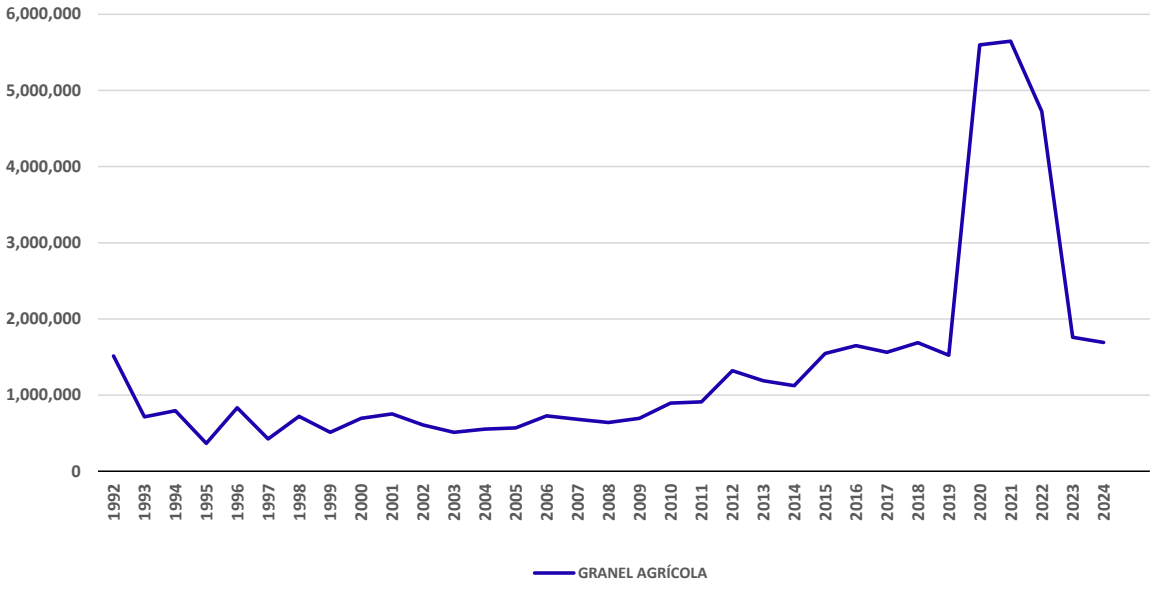
El granel agrícola muestra una evolución más estable, con una tendencia general al crecimiento, especialmente a partir de la década de 2000. Este comportamiento está estrechamente vinculado al papel del puerto como punto de entrada de granos y materias primas para la agroindustria nacional.

Figura 4.5 Movimiento de Carga de Granel Mineral en el Puerto de Manzanillo (1992 – 2024).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

Figura 4.6 Movimiento de Carga de Granel Agrícola en el Puerto de Manzanillo (1992 – 2024).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

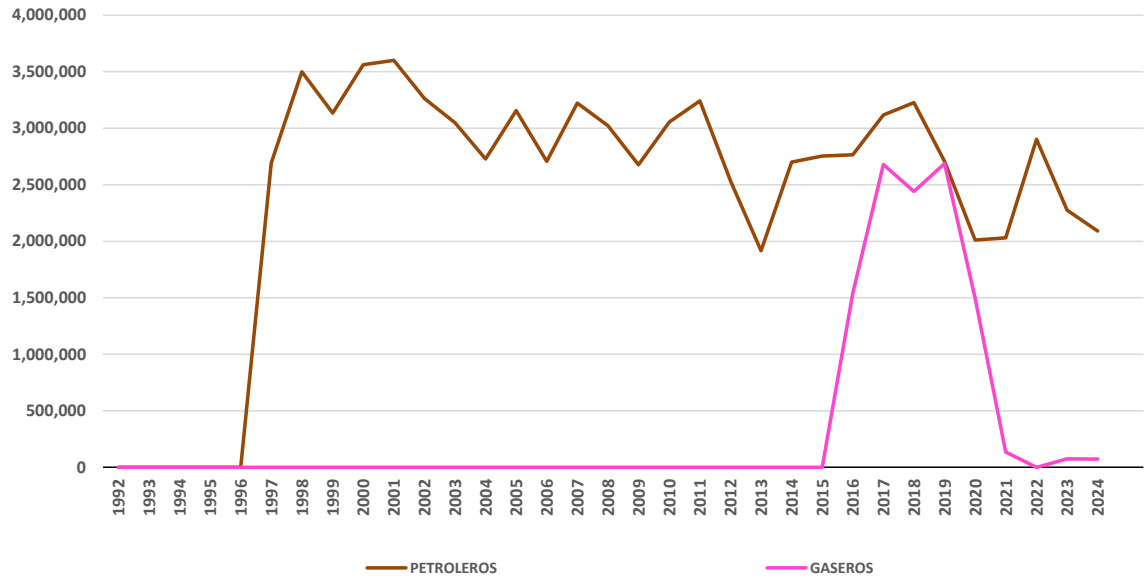
En los años más recientes del periodo analizado, el granel agrícola alcanza volúmenes elevados y relativamente constantes, lo que lo convierte en un tráfico estratégico para el abasto interno, más allá de su peso relativo frente al contenedor. Su evolución histórica evidencia que, aunque no domina el total del manejo de carga, constituye un componente clave para la seguridad alimentaria y la estabilidad de ciertas cadenas productivas.

4.2.6 Energéticos y otros tráficos

Los energéticos y derivados del petróleo muestran una evolución más ligada a decisiones de política energética, infraestructura específica y demanda interna. Aunque su volumen puede variar significativamente entre años, este tráfico mantiene un carácter estratégico y condiciona de manera importante la zonificación y los criterios de seguridad del puerto.

En el conjunto de la estadística histórica, los energéticos no desplazan a los contenedores en términos de volumen total, pero sí influyen de forma decisiva en la complejidad operativa y ambiental del sistema portuario.

Figura 4.7 Movimiento de Carga Petrolera y Gas en el Puerto de Manzanillo (1992 – 2024).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo.

4.2.7 Lectura integrada de la evolución histórica

La evolución del manejo de carga en Manzanillo entre 1992 y 2024 revela tres conclusiones estructurales:

1. El puerto ha experimentado un crecimiento sostenido de largo plazo, con mayor volatilidad en los años recientes.

2. La carga contenerizada se ha convertido en el eje dominante, desplazando progresivamente a la carga general tradicional.

3. Los graneles y energéticos mantienen un papel relevante y estratégico, reforzando el carácter multipropósito del puerto y la necesidad de una planeación integral.

Este comportamiento histórico explica tanto el éxito del puerto como los límites físicos y operativos actuales, y constituye la base técnica para justificar la expansión hacia la Laguna de Cuyutlán y la adopción de un enfoque port-led que permita absorber crecimiento futuro sin comprometer la eficiencia ni la sostenibilidad del sistema.

4.3 Expectativas de desarrollo portuario para 2026.

4.3.1 Contexto general.

El desarrollo portuario hacia el año 2026 se inscribe en un entorno de comercio marítimo caracterizado por una combinación de crecimiento moderado, elevada volatilidad operativa y cambios estructurales en la organización de las cadenas logísticas. A diferencia de ciclos anteriores, en los que el crecimiento del tráfico justificaba expansiones lineales de infraestructura, el escenario actual exige que los proyectos portuarios se orienten prioritariamente a mejorar la eficiencia efectiva, la resiliencia operativa y la integración logística, especialmente en los puertos con alta participación de tráfico contenerizado, que actúan como nodos críticos del comercio internacional.

En este contexto, el desarrollo portuario ya no se evalúa únicamente por la incorporación de metros de muelle o nuevas terminales, sino por la capacidad del sistema portuario para absorber picos de demanda, adaptarse a cambios de rutas y operar con fiabilidad bajo condiciones de disrupción. Este enfoque condiciona tanto las inversiones físicas como los modelos de gestión y coordinación institucional.

4.3.2 Expectativas internacionales de desarrollo portuario en 2026.

A nivel internacional, el tráfico de contenedores continuará siendo el principal motor de las decisiones de desarrollo portuario en 2026, aun cuando otros segmentos —graneles,

energéticos y cruceros— mantengan relevancia estratégica y, en algunos casos, presenten dinámicas propias de crecimiento. El énfasis en contenedores responde a que este segmento concentra los mayores requerimientos de capital, tecnología y coordinación logística, y a que su desempeño incide directamente en la competitividad de las cadenas de suministro globales.

Uno de los factores determinantes para 2026 es la persistencia de desajustes entre la capacidad de la flota contenerizada y la demanda efectiva, lo que genera presión sobre tarifas, escalas y utilización de infraestructura. Este fenómeno obliga a los puertos a competir menos por volumen nominal y más por productividad y confiabilidad, ya que las navieras tienden a concentrar escalas en puertos capaces de ofrecer tiempos de estadía reducidos, ventanas operativas confiables y buena conexión con el hinterland. En consecuencia, el desarrollo portuario internacional en 2026 se orientará a optimizar patios, sistemas de gestión de terminales, accesos terrestres y operaciones intermodales, más que a simples ampliaciones de frente de atraque.

Paralelamente, la tendencia hacia buques de mayor tamaño seguirá generando operaciones más concentradas y picos operativos más exigentes, lo que incrementa la presión sobre patios, gates y sistemas ferroviarios. En este sentido, los proyectos portuarios tenderán a incorporar soluciones de automatización selectiva, digitalización de procesos y planificación avanzada, no solo como herramientas de eficiencia, sino como mecanismos de reducción de riesgo operativo.

En cuanto a los graneles y energéticos, el desarrollo portuario internacional en 2026 estará fuertemente condicionado por la transición energética y por la reconfiguración de los flujos de materias primas. Los puertos especializados en graneles sólidos (minerales, agrícolas) buscarán mejorar eficiencia de carga y descarga, control ambiental y trazabilidad, mientras que los puertos energéticos deberán adaptarse a un escenario dual, en el que conviven combustibles tradicionales con nuevos vectores energéticos. Esto implica inversiones en infraestructura flexible, capaz de atender tanto tráficos consolidados como potenciales combustibles alternativos, sin comprometer la seguridad ni la continuidad operativa.

El segmento de cruceros, por su parte, presenta una lógica distinta. Para 2026 se espera una consolidación de la recuperación postpandemia, con énfasis en calidad de servicio, gestión de flujos turísticos y compatibilidad entre operaciones de cruceros y carga. En muchos puertos, el desarrollo asociado a cruceros se concentrará en terminales específicas, mejoras de accesibilidad urbana y mitigación de impactos, más que en grandes expansiones de capacidad portuaria propiamente dicha.

De forma transversal, la agenda ambiental y digital se consolida como un componente estructural del desarrollo portuario. En 2026, los puertos que aspiren a mantener o mejorar su posición competitiva deberán avanzar en electrificación de equipos, suministro eléctrico a buques, medición de emisiones y fortalecimiento de la ciberseguridad. Estas inversiones ya no se

consideran complementarias, sino habilitantes para la operación futura, especialmente en puertos con alto tráfico contenerizado y escalas frecuentes de grandes navieras.

4.3.3 Expectativas nacionales de desarrollo portuario en México para 2026

En el caso de México, el desarrollo portuario para 2026 se encuentra enmarcado por un sistema de planeación formal, articulado a través de los Programas Maestros de Desarrollo Portuario (PMDP) y gestionado por las Administraciones del Sistema Portuario Nacional (ASIPONA's). Este marco implica que las expectativas de desarrollo no se basan en decisiones ad hoc, sino en la ejecución progresiva de proyectos previamente definidos en términos de zonificación, vocación portuaria y crecimiento esperado.

El tráfico contenerizado constituye el eje central del desarrollo portuario nacional, tanto por su peso en el comercio exterior como por su impacto en la infraestructura terrestre asociada. En 2026, se espera que las inversiones se orienten principalmente a mejorar la capacidad operativa real de los puertos, mediante ampliaciones de terminales, modernización de equipos, aumento de capacidad de patios y mejoras en accesos carreteros y ferroviarios. El objetivo implícito es reducir tiempos de permanencia de buques y cargas, así como mitigar cuellos de botella que afectan la competitividad logística del país.

La participación del sector privado seguirá siendo un componente clave del desarrollo portuario mexicano, particularmente en terminales especializadas de contenedores y graneles. En este esquema, el Estado cumple un rol habilitador, garantizando condiciones de seguridad, ordenamiento, conectividad básica y certeza jurídica, mientras que los operadores privados aportan capital, tecnología y know-how operativo. Para 2026, este modelo continuará profundizándose, con proyectos que buscan maximizar el rendimiento de la infraestructura existente antes de avanzar hacia expansiones mayores.

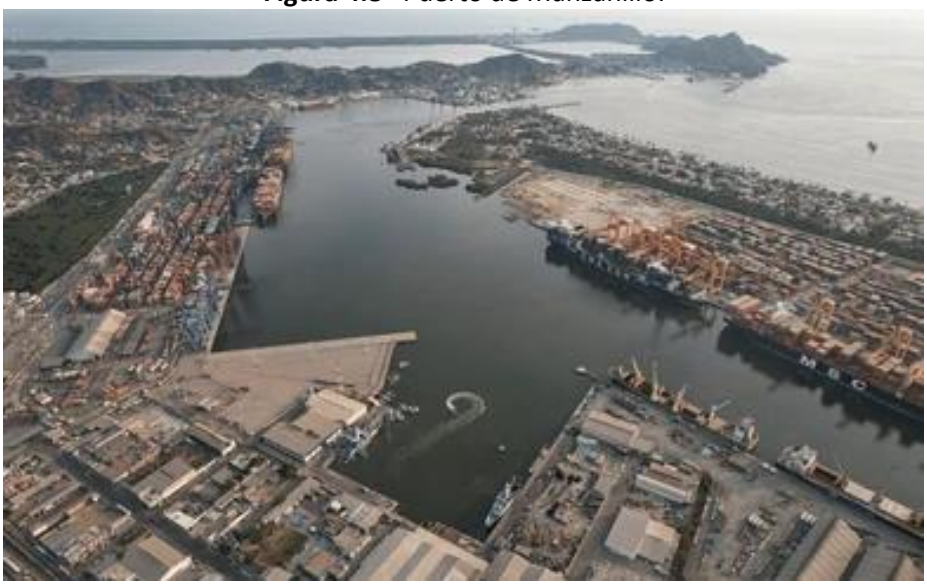
En el ámbito de los graneles y energéticos, el desarrollo portuario nacional responderá tanto a la demanda interna como a la posición de México en los mercados internacionales de materias primas y energía. Los puertos con vocación energética requerirán inversiones orientadas a seguridad, eficiencia y compatibilidad con nuevas exigencias ambientales, mientras que los puertos graneleros deberán enfocarse en mejoras operativas y control de impactos, especialmente en zonas con interacción cercana con áreas urbanas o ambientales sensibles.

Respecto a los cruceros, el desarrollo portuario para 2026 se centrará en la mejora de infraestructura dedicada y en la gestión de flujos turísticos, con el fin de maximizar el beneficio económico local sin afectar la operación de carga. En muchos casos, esto implica reforzar la segregación funcional dentro del puerto y mejorar la coordinación con autoridades locales y actores del sector turístico.

4.3.4 Puerto de Manzanillo: expectativas de desarrollo hacia 2026

El puerto de Manzanillo constituye el principal nodo portuario de México en términos de movimiento de carga contenerizada, y uno de los más relevantes de América Latina. Su papel estratégico dentro del Sistema Portuario Nacional condiciona de manera directa las prioridades y expectativas de desarrollo hacia 2026, ya que su desempeño incide no solo en la competitividad del comercio exterior mexicano, sino también en la eficiencia de los corredores logísticos que conectan el Pacífico con el centro y occidente del país.

Figura 4.8 Puerto de Manzanillo.



Fuente: ASIPONA Manzanillo.

Hacia 2026, el desarrollo del puerto de Manzanillo se encuentra marcado por un contexto de crecimiento contenido y alta volatilidad, en el que la expansión de los volúmenes no puede asumirse como un proceso lineal. La competencia regional entre puertos del Pacífico, la reorganización de servicios marítimos y la presión sobre la capacidad terrestre obligan a que el énfasis del desarrollo portuario se desplace desde la mera ampliación de infraestructura hacia la mejora de la productividad efectiva y la resiliencia operativa del sistema portuario.

En el ámbito de los contenedores, la principal expectativa de desarrollo para Manzanillo hacia 2026 es la consolidación de su capacidad para atender buques de gran tamaño bajo esquemas operativos cada vez más concentrados. La tendencia a menos escalas con mayores volúmenes por llamada genera picos operativos significativos que tensionan el sistema en su conjunto, particularmente en patios y accesos terrestres. En este contexto, la prioridad no reside

únicamente en el incremento de metros de muelle o en la incorporación de grúas de mayor capacidad, sino en asegurar que la infraestructura existente y futura pueda absorber dichos picos sin degradar los niveles de servicio.

La productividad portuaria se convierte así en el eje central del desarrollo del puerto de Manzanillo hacia 2026. Esto implica inversiones orientadas a la optimización de patios, a la mejora de los sistemas de gestión de terminales y a la coordinación más estrecha entre operadores, autoridad portuaria y actores del transporte terrestre. La evacuación eficiente de contenedores hacia el hinterland es un factor crítico, dado que las limitaciones en accesos carreteros y ferroviarios han demostrado ser uno de los principales cuellos de botella del sistema. En consecuencia, el desarrollo portuario debe entenderse de manera integrada, incorporando explícitamente la infraestructura y los nodos logísticos externos como parte del sistema funcional del puerto.

Desde la perspectiva de planeación, el desarrollo del puerto de Manzanillo hacia 2026 se apoya en los Programas Maestros de Desarrollo Portuario, que establecen la zonificación, las reservas de expansión y la vocación de las distintas áreas del recinto. No obstante, el entorno de volatilidad exige que la ejecución de estos programas se realice con criterios de flexibilidad y escalabilidad, priorizando proyectos con impacto directo en la reducción de cuellos de botella operativos y en la mejora de la confiabilidad del servicio. En este sentido, la expectativa es que las inversiones se estructuren de manera progresiva, evitando sobrecapacidad improductiva y permitiendo ajustes conforme evolucionen las condiciones del mercado.

En materia de descarbonización y transición energética, el puerto de Manzanillo enfrenta retos y oportunidades particulares. Su alto volumen de tráfico contenerizado implica una concentración significativa de emisiones locales asociadas a equipos de manipulación y a la estancia de buques. Para 2026, se espera un avance gradual en la electrificación de equipos y en la mejora de la eficiencia energética de las terminales, así como el fortalecimiento de la infraestructura eléctrica portuaria. Aunque el suministro eléctrico a buques aún se encuentra en una etapa incipiente, la preparación del puerto para este tipo de soluciones se perfila como un elemento relevante de competitividad futura, especialmente frente a exigencias ambientales crecientes de las navieras.

El puerto de Manzanillo también mantiene una vocación relevante en graneles y energéticos, particularmente en tráficos vinculados al abastecimiento regional y nacional. En estos segmentos, el desarrollo hacia 2026 se orienta a reforzar la seguridad operativa, el control ambiental y la eficiencia de los procesos de carga y descarga, así como a garantizar la convivencia funcional entre distintos tipos de tráfico dentro del recinto portuario. La coexistencia de contenedores, graneles y energéticos exige una gestión cuidadosa de la zonificación y de los flujos internos, con el fin de minimizar interferencias y riesgos.

En cuanto al segmento de cruceros, si bien no constituye el eje principal del puerto, su desarrollo hacia 2026 se vincula a la mejora de infraestructura dedicada y a la gestión de la interacción puerto–ciudad. La expectativa es consolidar este tráfico de manera compatible con la operación comercial, evitando impactos negativos sobre la logística portuaria y maximizando los beneficios económicos para la región.

Un componente clave del desarrollo del puerto de Manzanillo hacia 2026 es la profundización del enfoque de desarrollo port-led. La expansión de zonas logísticas, patios externos y plataformas intermodales en el entorno del puerto resulta fundamental para absorber los picos de salida de contenedores y reducir la presión sobre el recinto portuario. Este enfoque refuerza el papel de Manzanillo como nodo logístico nacional, en el que el puerto actúa como articulador de un sistema más amplio que incluye infraestructura terrestre, parques logísticos e industria asociada.

En síntesis, las expectativas de desarrollo del puerto de Manzanillo hacia 2026 se centran en consolidar su liderazgo en carga contenerizada mediante mejoras sustantivas en productividad, resiliencia y coordinación logística, integrando de manera ordenada los segmentos de graneles, energéticos y cruceros. El éxito de este proceso dependerá de la capacidad del sistema portuario para transformar la planificación y la inversión en reducción efectiva de cuellos de botella, mejora de la confiabilidad operativa y adaptación a las nuevas exigencias ambientales y del mercado, asegurando así la competitividad de Manzanillo como principal puerto del país.

4.3.5 Consideraciones finales

En síntesis, las expectativas de desarrollo portuario para 2026, tanto a nivel internacional como nacional, apuntan a un modelo en el que el tráfico contenerizado actúa como principal catalizador de inversión y modernización, mientras que los segmentos de graneles, energéticos y cruceros se integran de manera complementaria, con soluciones específicas a sus dinámicas operativas. El énfasis se desplaza desde la expansión cuantitativa hacia la eficiencia sistémica, entendida como la capacidad del puerto para operar con fiabilidad, flexibilidad y sostenibilidad en un entorno logístico cada vez más exigente.

4.4 Mercado: Crecimiento “Frágil” y Elevada Volatilidad.

El desarrollo portuario hacia 2026 se produce en un contexto de mercado marítimo caracterizado por un crecimiento estructuralmente frágil, acompañado de niveles elevados de volatilidad operativa y comercial. A diferencia de etapas anteriores, en las que el crecimiento del comercio internacional se traducía de forma relativamente directa en aumentos sostenidos de tráfico portuario, el escenario actual presenta una mayor disociación entre volumen global, distribución geográfica de los flujos y rentabilidad de las operaciones.

En el segmento de contenedores, esta fragilidad se manifiesta, en primer lugar, en el desajuste entre la capacidad de la flota y la demanda efectiva. La entrada en servicio de buques de gran tamaño, ordenados en ciclos previos de expectativas de crecimiento, ha generado una oferta de capacidad que supera el ritmo real de expansión del comercio, presionando a la baja las tarifas y obligando a las navieras a reconfigurar servicios, cancelar escalas o concentrar llamadas en un número reducido de puertos altamente eficientes. Para los puertos, este fenómeno implica que el crecimiento del tráfico no está garantizado y que la captación de escalas depende cada vez más de factores como la productividad, la confiabilidad operativa y la integración logística, más que de la mera disponibilidad de infraestructura.

La volatilidad del mercado se ve amplificada por factores geopolíticos y operativos que afectan directamente a las rutas marítimas y a la regularidad de los servicios. Las disrupciones en corredores estratégicos, los desvíos de rutas y las restricciones temporales en infraestructuras clave introducen cambios abruptos en los patrones de tráfico, generando picos de demanda en determinados puertos y caídas súbitas en otros. Esta dinámica dificulta la planificación a medio plazo y obliga a los puertos a operar con márgenes de flexibilidad mayores, tanto en capacidad física como en organización operativa.

Desde el punto de vista del desarrollo portuario, la combinación de crecimiento frágil y volatilidad elevada condiciona la naturaleza de las inversiones previstas para 2026. En lugar de grandes expansiones lineales basadas en proyecciones optimistas de volumen, se priorizan proyectos que aumenten la capacidad efectiva y adaptable del puerto: optimización de patios, mejora de flujos internos, refuerzo de accesos terrestres y sistemas de gestión que permitan absorber variaciones significativas de tráfico sin degradar el nivel de servicio. Este enfoque es especialmente crítico en terminales de contenedores, donde los picos operativos derivados de escalas de megabuques pueden saturar rápidamente infraestructuras insuficientemente preparadas.

La volatilidad del mercado también tiene efectos indirectos sobre otros segmentos. En los graneles, tanto sólidos como líquidos, la incertidumbre en precios y flujos comerciales puede traducirse en variaciones significativas en los volúmenes manejados, afectando la utilización de instalaciones especializadas y la programación de operaciones. En el caso de los energéticos, la transición hacia nuevas fuentes y la coexistencia con combustibles tradicionales añaden un componente adicional de incertidumbre, que obliga a los puertos a planificar infraestructuras versátiles y escalables. Incluso en el segmento de cruceros, la sensibilidad a factores económicos y geopolíticos introduce una mayor variabilidad en las escalas y en la estacionalidad, lo que refuerza la necesidad de infraestructuras y modelos de gestión flexibles.

En este contexto, el mercado portuario de 2026 se caracteriza menos por la previsibilidad de los volúmenes y más por la necesidad de gestionar la incertidumbre. El desarrollo portuario responde, por tanto, a un cambio de paradigma: la competitividad ya no se basa únicamente en crecer en capacidad instalada, sino en reducir la exposición al riesgo de mercado, asegurar la

continuidad operativa bajo escenarios cambiantes y ofrecer a los usuarios un servicio confiable incluso en condiciones de alta volatilidad. Esta lógica explica por qué, en 2026, el énfasis del desarrollo portuario se sitúa en la resiliencia, la productividad integral y la capacidad de adaptación del sistema portuario en su conjunto.

4.5 Productividad y Megabuques: Menos Llamadas, Mayor Concentración de Picos Operativos.

El desarrollo portuario hacia 2026 está fuertemente condicionado por la consolidación del uso de buques portacontenedores de gran y muy gran tamaño, fenómeno que ha transformado de manera estructural la relación entre frecuencia de escalas, volumen manejado por llamada y exigencias operativas para los puertos. Si bien los megabuques permiten economías de escala en el transporte marítimo, su impacto en la operación portuaria se traduce en un esquema de menos llamadas, pero con volúmenes significativamente mayores por escala, lo que genera picos operativos cada vez más intensos y complejos de gestionar.

Figura 4.9 Megabuque Portacontenedores en el Puerto de Manzanillo.

Fuente: https://thelogisticsworld.com/.

En términos prácticos, esta dinámica implica que el crecimiento del tráfico contenerizado no se manifiesta necesariamente como un aumento proporcional del número de escalas, sino como una concentración de movimientos en ventanas temporales más reducidas. Cada arribo de un megabuque supone la manipulación de miles de contenedores en un periodo acotado, con altas exigencias de rendimiento en muelle, patio y accesos terrestres. Para los puertos, el desafío

no reside únicamente en atender el volumen total anual, sino en ser capaces de absorber estos picos sin que se deterioren los indicadores clave de desempeño, como el tiempo de estadía del buque, la congestión en patios o la fluidez del gate.

Esta situación eleva la productividad portuaria a una condición crítica de competitividad. En 2026, la productividad deja de ser un indicador aislado del desempeño de una terminal para convertirse en una medida del rendimiento del sistema portuario en su conjunto, que incluye la coordinación entre autoridad portuaria, terminales, servicios marítimos, transporte terrestre y usuarios finales. La capacidad de un puerto para manejar megabuques de forma eficiente depende tanto de la dotación de grúas y del rendimiento por hora como de la disponibilidad de patios, la capacidad de evacuación de carga y la sincronización de los flujos de información.

El impacto de los megabuques no se limita al frente de atraque[6]. La descarga y carga masiva de contenedores en un corto intervalo genera presiones inmediatas sobre el patio de almacenamiento, incrementando la densidad y complejidad de las operaciones de apilamiento y reposicionamiento. Asimismo, los picos de salida y entrada de carga tensionan los accesos carreteros y ferroviarios, lo que puede provocar congestión externa al puerto y extender los efectos del pico operativo más allá del recinto portuario. Por ello, el desarrollo portuario en 2026 prioriza inversiones que mejoren la capacidad de respuesta del sistema ante estas concentraciones, tales como ampliación y reconfiguración de patios, optimización de flujos internos, mejora de accesos y fortalecimiento de la intermodalidad.

Desde una perspectiva de planeación, la tendencia a menos llamadas y mayores picos obliga a replantear los criterios tradicionales de dimensionamiento de infraestructura. Ya no resulta suficiente diseñar instalaciones en función de promedios anuales o diarios; se vuelve necesario considerar escenarios de máxima exigencia, asociados a la coincidencia de escalas de grandes buques o a la recuperación de servicios tras disrupciones. En este sentido, el desarrollo portuario orientado a 2026 busca dotar a los puertos de mayor elasticidad operativa, entendida como la capacidad de escalar temporalmente su rendimiento sin incurrir en pérdidas significativas de eficiencia o calidad de servicio.

Aunque este fenómeno se observa con mayor intensidad en el tráfico contenerizado, sus efectos se extienden a otros segmentos. En los graneles, la utilización de buques de mayor capacidad también puede generar concentraciones de operación que requieren equipos y sistemas de evacuación suficientemente robustos. En el ámbito energético, la llegada de grandes buques tanque demanda altos estándares de seguridad y coordinación, especialmente cuando coinciden con operaciones de otros tráficos. En el caso de los cruceros, si bien la lógica es distinta,

[6] La irrupción de los megabuques (capaces de transportar más de 20,000 TEU's) ha transformado la logística marítima, generando un conflicto directo entre las economías de escala para las navieras y la productividad portuaria en tierra. Si bien reducen los costos unitarios de transporte por contenedor, imponen retos operativos significativos que pueden saturar las terminales si no están adecuadamente equipadas.

la recepción de buques de gran capacidad de pasaje genera igualmente picos temporales que afectan la gestión portuaria y la interacción con la ciudad.

En consecuencia, la expectativa para 2026 es que el desarrollo portuario se oriente menos a incrementar el número de escalas atendidas y más a maximizar el rendimiento por escala, asegurando que los picos asociados a megabuques puedan ser gestionados de manera eficiente y segura. La productividad, entendida de forma integral, se consolida, así como un factor estratégico que condiciona la capacidad de los puertos para insertarse de manera competitiva en las redes marítimas globales y para sostener su crecimiento en un entorno de alta concentración y volatilidad operativa.

4.5.1 Implicaciones para la planificación e inversión portuaria

Las dinámicas de crecimiento frágil del mercado y la creciente concentración operativa derivada del uso de megabuques obligan a replantear los criterios tradicionales de planificación e inversión portuaria de cara a 2026. En este escenario, la planificación deja de apoyarse en proyecciones lineales de crecimiento de volumen para orientarse hacia modelos que priorizan la resiliencia, la flexibilidad operativa y la eficiencia sistémica del puerto como conjunto de infraestructuras, servicios y procesos interconectados.

Desde el punto de vista de la planificación, una primera implicación es la necesidad de adoptar enfoques de dimensionamiento basados en escenarios críticos, más que en promedios históricos. La concentración de movimientos asociada a megabuques y a reconfiguraciones de servicios marítimos implica que los picos de demanda pueden superar con facilidad la capacidad diseñada bajo supuestos medios. En consecuencia, los planes de desarrollo portuario para 2026 tienden a incorporar análisis de máxima exigencia operativa, considerando coincidencias de escalas, recuperación tras disrupciones y variaciones abruptas de flujo, con el objetivo de evitar cuellos de botella que comprometan la confiabilidad del puerto.

En términos de inversión, este cambio de enfoque se traduce en una priorización de proyectos que incrementen la capacidad efectiva y utilizable, más que la capacidad nominal. En el ámbito de los contenedores, esto implica destinar recursos a la optimización y ampliación de patios, a la mejora de los sistemas de gestión de terminal (TOS) y a la digitalización de los flujos de información, de modo que el aumento de volumen por escala pueda ser absorbido sin generar congestión interna. La inversión en equipamiento de muelle sigue siendo relevante, pero su efectividad depende cada vez más de la coherencia con el resto de la cadena operativa, particularmente con la evacuación terrestre de la carga.

La conectividad con el hinterland se convierte así en un elemento central de la estrategia de inversión. La experiencia reciente ha mostrado que las limitaciones en accesos carreteros y ferroviarios pueden neutralizar los beneficios de inversiones significativas en infraestructura portuaria. Por ello, en 2026 la planificación portuaria incorpora con mayor énfasis proyectos de

mejora y expansión de accesos, patios intermodales y nodos logísticos externos, entendidos como extensiones funcionales del puerto. Este enfoque es especialmente crítico en puertos con alto tráfico contenerizado, donde los picos de salida de carga tras la atención de megabuques generan presiones inmediatas sobre la red terrestre.

Otra implicación relevante es la necesidad de introducir criterios de flexibilidad y modularidad en el diseño de las inversiones. Dada la volatilidad del mercado y la incertidumbre sobre la evolución de los flujos, los proyectos portuarios para 2026 tienden a estructurarse en fases, con soluciones que puedan ampliarse o adaptarse conforme evolucionen las condiciones de demanda. Este principio es aplicable tanto a terminales de contenedores como a instalaciones de graneles y energéticos, donde la coexistencia de tráficos tradicionales y emergentes exige infraestructuras capaces de reconvertirse o coexistir sin comprometer la seguridad ni la eficiencia.

Desde una perspectiva económica y financiera, el nuevo contexto refuerza la importancia de evaluar las inversiones no solo en función de su capacidad de generar volumen, sino de su impacto en indicadores de desempeño operativo y reducción de riesgo. Proyectos que disminuyen el tiempo de estadía de buques, reducen la variabilidad en los tiempos de despacho o aumentan la previsibilidad de las operaciones adquieren un valor estratégico, aun cuando no incrementen de forma inmediata el volumen total manejado. En un entorno de crecimiento frágil, la capacidad de sostener operaciones estables y confiables se convierte en un factor clave para atraer y retener servicios marítimos.

Finalmente, la planificación e inversión portuaria para 2026 deben integrar de manera explícita los requerimientos asociados a la transición energética y a la digitalización. La electrificación de equipos, el suministro eléctrico a buques, la gestión de datos operativos y el fortalecimiento de la ciberseguridad ya no pueden considerarse elementos accesorios, sino componentes estructurales del desarrollo portuario. Su incorporación temprana en los planes de inversión permite evitar costos de adaptación posteriores y posiciona al puerto para cumplir con exigencias regulatorias y de mercado cada vez más estrictas.

En conjunto, las implicaciones para la planificación e inversión portuaria en 2026 apuntan a un modelo de desarrollo más selectivo y estratégico, en el que el éxito no se mide únicamente por la magnitud del CAPEX ejecutado, sino por la capacidad del puerto para transformar esa inversión en productividad sostenible, resiliencia operativa y competitividad logística en un entorno de alta incertidumbre.

4.6 Descarbonización y “puertos energéticos”

El desarrollo portuario hacia 2026 está crecientemente condicionado por la agenda de descarbonización del transporte marítimo y de las cadenas logísticas, lo que sitúa a los puertos en un papel estratégico que trasciende su función tradicional como nodos de intercambio modal. En este contexto, los puertos evolucionan progresivamente hacia el concepto de “puertos

energéticos", entendidos como plataformas capaces de suministrar, gestionar y facilitar nuevas soluciones energéticas para buques, terminales e industrias asociadas.

En el segmento de contenedores, la descarbonización se manifiesta en una doble exigencia. Por un lado, las navieras enfrentan presiones regulatorias y comerciales para reducir emisiones, lo que incrementa la demanda de infraestructuras portuarias que permitan operaciones más limpias, como el suministro eléctrico a buque (OPS o shore power) durante la estancia en puerto. Por otro lado, los operadores de terminales se ven impulsados a electrificar equipos de manipulación, optimizar consumos energéticos y reducir emisiones locales, tanto por razones ambientales como por eficiencia operativa y aceptación social. En consecuencia, el desarrollo portuario para 2026 incorpora inversiones significativas en redes eléctricas internas, subestaciones, capacidad de conexión a la red y, en algunos casos, integración de fuentes renovables.

Figura 4.10 Transporte Marítimo y Descarbonización.

Fuente: https://piernext.portdebarcelona.cat/.

Más allá de la electrificación, la transición energética introduce un nivel adicional de complejidad asociado a la incertidumbre sobre los combustibles marítimos del futuro. La coexistencia de combustibles convencionales con alternativas emergentes (como combustibles sintéticos, hidrógeno o derivados) obliga a los puertos a adoptar enfoques prudentes y flexibles en

su desarrollo. Para 2026, la expectativa no es una adopción masiva y homogénea de nuevos combustibles, sino la preparación progresiva del sistema portuario para atender diferentes escenarios tecnológicos, evitando inversiones rígidas que puedan quedar obsoletas. Esta lógica es especialmente relevante en puertos con fuerte vocación contenerizada, donde la diversidad de flotas y servicios exige soluciones energéticas compatibles con múltiples estándares.

En el ámbito de los puertos energéticos, el desarrollo portuario también se vincula estrechamente con los tráficos de graneles líquidos y sólidos relacionados con energía. Los puertos especializados en energéticos deberán reforzar sus capacidades de seguridad, control ambiental y gestión de riesgos, al tiempo que exploran oportunidades para diversificar su rol dentro de la cadena energética. En muchos casos, esto implica pasar de ser simples puntos de transferencia de productos a convertirse en nodos de almacenamiento, transformación o redistribución energética, integrados con redes industriales y logísticas más amplias.

La descarbonización tiene asimismo implicaciones para la gobernanza portuaria y la gestión de datos. La medición, reporte y verificación de emisiones se convierten en requisitos crecientemente relevantes para operadores y usuarios del puerto. En este sentido, el desarrollo portuario hacia 2026 incorpora no solo infraestructura física, sino también capacidades digitales y organizativas para gestionar información ambiental de manera consistente y transparente. Este aspecto es clave para mantener la competitividad del puerto en cadenas logísticas que demandan trazabilidad ambiental y cumplimiento de estándares internacionales.

En conjunto, la descarbonización redefine el desarrollo portuario como un proceso que combina infraestructura energética, innovación tecnológica y adaptación institucional. Para 2026, los puertos que logren avanzar de manera ordenada en esta transición estarán mejor posicionados para atraer tráficos contenerizados de largo plazo, sostener operaciones energéticas seguras y responder a las crecientes exigencias ambientales del comercio marítimo global.

4.7 Desarrollo “Port-led”: Más Logística e Industria Alrededor del Puerto.

Paralelamente a las transformaciones operativas y energéticas, el desarrollo portuario hacia 2026 se caracteriza por una intensificación del enfoque conocido como desarrollo “port-led”, en el que el puerto actúa como catalizador de actividades logísticas, industriales y de valor añadido en su entorno inmediato y en su hinterland ampliado. Este modelo responde a la necesidad de capturar mayor valor económico del tráfico portuario y de mejorar la eficiencia sistémica de las cadenas logísticas.

En el caso del tráfico contenerizado, el desarrollo port-led se traduce en la expansión de parques logísticos, centros de distribución, zonas de consolidación y desconsolidación de carga, y plataformas intermodales conectadas funcionalmente con el puerto. La creciente concentración de volúmenes por escala, asociada al uso de megabuques, genera picos de salida de contenedores que difícilmente pueden ser absorbidos únicamente dentro del recinto portuario. En este

contexto, las instalaciones logísticas externas actúan como válvulas de descompresión, permitiendo distribuir los flujos en el tiempo y el espacio, y reduciendo la congestión interna del puerto.

Desde una perspectiva de desarrollo, este enfoque implica que la competitividad portuaria ya no depende exclusivamente de lo que ocurre dentro de los límites físicos del puerto, sino de la calidad y capacidad del ecosistema logístico asociado. Para 2026, se espera que los proyectos portuarios integren de forma más explícita la planificación de infraestructuras externas, incluyendo accesos, patios intermodales, zonas logísticas y conexiones ferroviarias, como parte del sistema portuario ampliado. Esta integración resulta especialmente relevante en corredores logísticos estratégicos y en puertos con vocación de hub regional.

El desarrollo port-led también adquiere relevancia en los graneles y energéticos, donde la proximidad de instalaciones industriales puede reducir costos logísticos, mejorar la eficiencia de la cadena de suministro y fomentar sinergias productivas. En estos casos, el puerto funciona como nodo de entrada y salida de materias primas, mientras que las actividades de transformación, almacenamiento o distribución se localizan en áreas adyacentes, configurando verdaderos complejos logístico-industriales. Para 2026, esta lógica se ve reforzada por la necesidad de optimizar cadenas más cortas y resilientes, en un entorno de incertidumbre global.

En el segmento de cruceros, aunque el desarrollo port-led adopta una forma distinta, el principio es similar. El puerto actúa como punto de articulación entre la actividad marítima y el sistema urbano-turístico, lo que exige una planificación cuidadosa para maximizar beneficios económicos sin generar impactos negativos. Las inversiones se orientan a mejorar la conectividad, la gestión de flujos de pasajeros y la integración del puerto con la ciudad, reforzando su papel como motor de desarrollo local.

Desde el punto de vista institucional, el desarrollo port-led implica una mayor coordinación entre autoridades portuarias, gobiernos locales, operadores logísticos e inversionistas privados. Para 2026, la expectativa es que los puertos asuman un rol más activo como planificadores y facilitadores del desarrollo territorial, promoviendo proyectos que amplíen la capacidad logística del sistema sin sobrecargar el recinto portuario. Esta función resulta clave para sostener el crecimiento del tráfico contenerizado y para integrar de manera eficiente los distintos segmentos de actividad portuaria.

En síntesis, el desarrollo port-led consolida al puerto como un nodo central de sistemas productivos y logísticos más amplios. En 2026, los puertos que logren articular eficazmente infraestructura portuaria, logística externa e industria asociada estarán mejor preparados para gestionar la volatilidad del mercado, absorber picos operativos y maximizar el impacto económico y estratégico de su actividad.

5.0 PROYECCIONES DE CARGA.

5.1 Fundamentos Técnicos, Económicos y de Mercado de los Escenarios de Proyección de Carga al Horizonte 2050.

Los escenarios de proyección de carga al horizonte 2050 no son simples extrapolaciones estadísticas. Se construyen sobre tres capas:

- Capa económica (macro): crecimiento del comercio mundial, nearshoring, PIB México–EE. UU., elasticidad comercio/PIB.
- Capa de mercado portuario: posicionamiento competitivo de Manzanillo en el Pacífico, participación frente a Lázaro Cárdenas y puertos de EE. UU.
- Capa técnica-operativa: capacidad instalada, restricciones físicas, productividad y factibilidad de expansión.

Los tres escenarios (Conservador, Base y Optimista) varían en supuestos estructurales sobre estas capas.

5.1.1 Marco metodológico para la construcción de escenarios.

La proyección de carga del sistema portuario Manzanillo–Cuyutlán al horizonte 2050 se desarrolló mediante un enfoque de escenarios estructurales, diseñado para capturar la incertidumbre asociada a variables macroeconómicas, dinámicas del comercio internacional, evolución del proceso de relocalización productiva (nearshoring) y condiciones técnicas de expansión portuaria.

En lugar de aplicar una extrapolación estadística simple de las tasas históricas, se adoptó un enfoque integrado que articula tres dimensiones fundamentales. En primer lugar, la dimensión macroeconómica, que considera el crecimiento del comercio mundial, el desempeño del PIB de México y Norteamérica, así como la elasticidad comercio/PIB observada históricamente. En segundo lugar, la dimensión de mercado portuario, que evalúa el posicionamiento competitivo de Manzanillo frente a otros puertos del Pacífico mexicano y de la costa oeste del continente americano. En tercer lugar, la dimensión técnica-operativa, que incorpora las restricciones físicas del sistema, la velocidad de implementación de infraestructura y la productividad esperada de los distintos subsistemas (muelle, patio, accesos y ferrocarril).

Bajo este marco se definieron tres trayectorias coherentes y mutuamente excluyentes: escenario Conservador, escenario Base y escenario Optimista. Cada uno responde a supuestos diferenciados, pero internamente consistentes.

5.1.2 Escenario Conservador.

El escenario conservador parte de un entorno macroeconómico caracterizado por un crecimiento moderado del comercio mundial, en un rango promedio anual cercano a 2.0%–2.5% real de largo plazo. Este supuesto es consistente con etapas históricas posteriores a crisis financieras globales o periodos prolongados de bajo dinamismo económico. En este contexto, el PIB de México evolucionaría a tasas promedio entre 1.5% y 2.0%, reflejando una expansión económica estable pero limitada por factores estructurales internos.

Desde la perspectiva de comercio exterior, el proceso de nearshoring se materializaría de forma parcial y gradual. Si bien México mantendría ventajas geográficas frente a Asia para abastecer el mercado norteamericano, la velocidad de captación de inversión manufacturera estaría condicionada por restricciones energéticas, disponibilidad de infraestructura logística terrestre y certidumbre regulatoria. Bajo estas condiciones, la elasticidad comercio/PIB tendería a niveles inferiores a los observados durante fases de expansión global intensiva.

En términos de mercado portuario, Manzanillo conservaría su liderazgo nacional, pero el crecimiento incremental sería compartido con otros puertos mexicanos, particularmente en tráficos especializados o en segmentos donde existan ventajas competitivas diferenciadas. El transbordo internacional no experimentaría un crecimiento estructural significativo, por lo que el puerto continuaría operando principalmente como puerta de entrada y salida del hinterland tradicional.

Desde la óptica técnica, la expansión hacia Cuyutlán se implementaría con prudencia, en fases que acompañen el crecimiento efectivo de la demanda. La infraestructura existente alcanzaría niveles de utilización elevados antes de habilitar nuevas capacidades, situándose en rangos del orden de 70%–75% de ocupación en subsistemas críticos. Este patrón implicaría periodos recurrentes de presión operativa, aunque sin saturación estructural permanente.

El resultado agregado de estos supuestos es una tasa promedio de crecimiento de largo plazo del orden de 2.5%–3.0% anual. Este escenario constituye el piso prudente para efectos de evaluación financiera y análisis de riesgo, pues asume condiciones macroeconómicas moderadas y un proceso de expansión portuaria contenido.

5.1.3 Escenario Base.

El escenario base representa la trayectoria más probable bajo condiciones macroeconómicas estables y continuidad en las tendencias recientes del comercio internacional. Se asume un crecimiento del comercio mundial en el rango de 3.0%–3.5% anual, coherente con promedios históricos de expansión global en ausencia de crisis sistémicas prolongadas. En este

contexto, el PIB mexicano crecería entre 2.5% y 3.0% anual, impulsado por manufactura de exportación, inversión en logística y mayor integración regional.

El proceso de nearshoring se consolidaría en sectores estratégicos como automotriz, electrónica, electrodomésticos y bienes intermedios. Esta relocalización productiva reforzaría el papel de México como plataforma manufacturera para Norteamérica, generando mayor volumen de comercio exterior en contenedores. Bajo este escenario, la elasticidad comercio/PIB se mantendría en niveles similares a los observados en la última década.

Desde el punto de vista de mercado portuario, Manzanillo consolidaría su posición como principal nodo del Pacífico mexicano. La carga contenerizada incrementaría gradualmente su participación dentro del mix total, mientras que los graneles y otros tráficos mantendrían un comportamiento estable en términos relativos. El transbordo regional podría crecer de forma moderada, aunque sin transformar estructuralmente el perfil del puerto.

En el plano técnico, la expansión de Cuyutlán se ejecutaría conforme a un programa planificado, evitando saturaciones prolongadas. La participación del ferrocarril aumentaría progresivamente, reduciendo presión sobre el sistema de puertas y mejorando la rotación de patios. La productividad de grúas STS, patios y sistemas de control operaría dentro de rangos optimizados, manteniendo niveles de utilización objetivo entre 60% y 65%, consistentes con estándares internacionales de eficiencia sin congestión.

Bajo estas premisas, el crecimiento promedio de largo plazo se ubicaría entre 3.5% y 4.0% anual. Este escenario constituye la base de planeación estratégica y sustenta la programación escalonada de inversiones en frentes, patios e infraestructura intermodal.

5.1.4 Escenario Optimista.

El escenario optimista contempla un entorno de alto dinamismo económico internacional, con comercio mundial creciendo entre 3.5% y 4.5% anual sostenido en el largo plazo. Este contexto estaría asociado a una expansión prolongada del comercio intraindustrial y a la consolidación de cadenas de suministro regionalizadas.

En este marco, el proceso de nearshoring se intensificaría significativamente. México se posicionaría como plataforma manufacturera central para Norteamérica, captando inversión extranjera directa de forma sostenida. La elasticidad comercio/PIB sería superior al promedio histórico reciente, reflejando un crecimiento acelerado del comercio exterior respecto al producto.

En términos de mercado, Manzanillo evolucionaría hacia un rol de hub regional del Pacífico oriental. La mayor concentración de servicios directos Asia–México y el incremento del

transbordo internacional reforzarían su centralidad logística. La carga contenerizada dominaría ampliamente el mix total, incrementando su participación estructural.

Desde la dimensión técnica, la expansión en Cuyutlán se desarrollaría con mayor rapidez y escala. El sistema ferroviario operaría de manera robusta 24/7, con elevada participación modal. La productividad de muelle y patio alcanzaría niveles superiores gracias a mayor automatización, digitalización y economías de escala. El diseño de infraestructura incorporaría configuraciones de alta densidad y mayor número de frentes simultáneos.

En este escenario, la tasa promedio de crecimiento podría situarse entre 4.5% y 5.0% anual de largo plazo. La magnitud de las inversiones requeridas sería mayor, pero también lo sería la capacidad del puerto para capturar flujos regionales estratégicos.

5.1.5 Interpretación estratégica.

La diferencia entre escenarios no radica únicamente en una variación de tasas de crecimiento, sino en el posicionamiento estructural del sistema portuario. En el escenario conservador, la expansión en Cuyutlán actúa principalmente como mecanismo de alivio operativo. En el escenario base, constituye la evolución natural del sistema ante crecimiento sostenido. En el escenario optimista, se convierte en condición necesaria para capturar oportunidades estratégicas y evitar pérdida de competitividad regional.

Este enfoque escalonado permite que la planeación de infraestructura se mantenga flexible, adaptable y financieramente robusta frente a distintos contextos macroeconómicos.

Tabla 5.1 Comparación estructural de escenarios.

Variable estratégica	Conservador	Base	Optimista
Crecimiento comercio mundial	Bajo	Moderado	Alto
Intensidad del nearshoring	Parcial	Consolidado	Acelerado
Participación ferroviaria	Estable	Creciente	Alta
Productividad portuaria	Mejora marginal	Mejora continua	Mejora acelerada
Rol regional	Liderazgo nacional	Nodo dominante	Hub regional
Crecimiento anual a largo plazo	2.5% – 3.0%	3.5% – 4.0%	4.5% – 5.0%

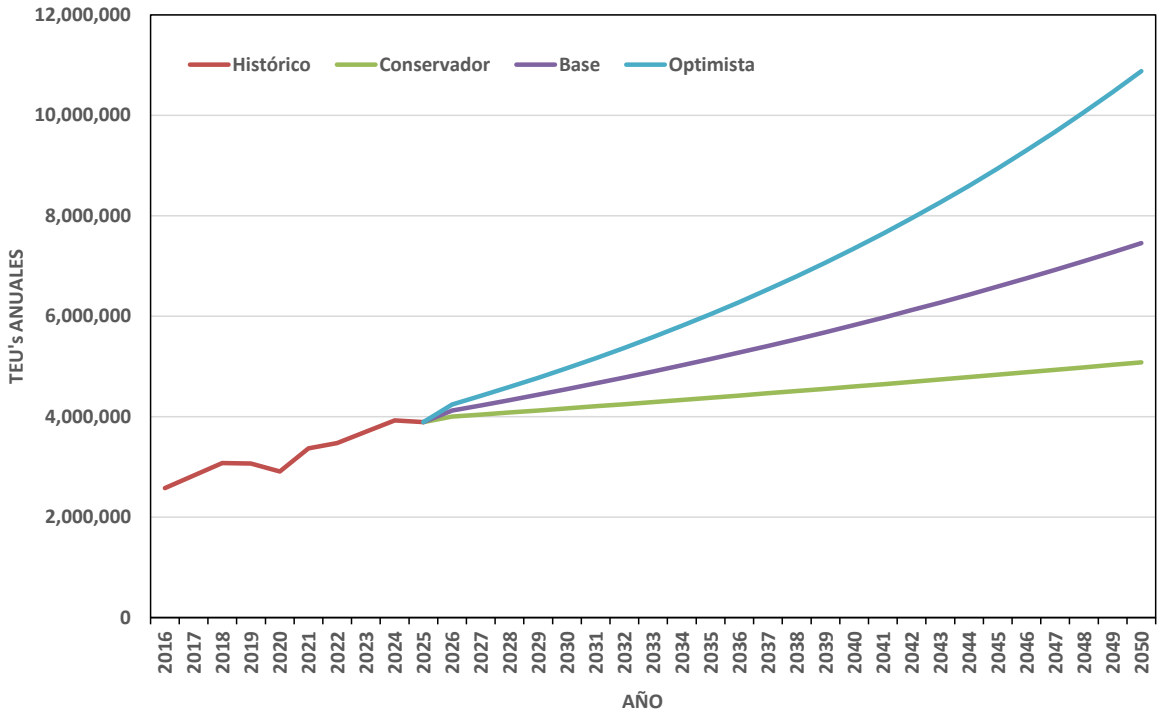
Fuente: Elaboración propia, 2026.

5.2 Proyección de Carga al Horizonte 2050.

La proyección de carga al año 2050 se desarrolló tomando como punto de partida un volumen base aproximado de 4.0 millones de TEU anuales, representativo del nivel actual del sistema portuario. A partir de este valor inicial se aplicaron tasas de crecimiento anual compuesto (CAGR) diferenciadas por escenario, en un horizonte de 25 años.

En el escenario conservador se adoptó una tasa de crecimiento anual compuesta de 3.0%, consistente con un entorno de comercio internacional moderado y nearshoring gradual. Bajo crecimiento compuesto durante 25 años, el factor acumulado es aproximadamente 2.09 veces el volumen inicial. Esto conduce a una proyección al 2050 cercana a 8.4 millones de TEU anuales. En este escenario el puerto prácticamente duplicaría su tamaño actual, pero mantendría un perfil predominantemente nacional, con expansión gradual y controlada de infraestructura.

Figura 5.1 Proyección de Carga Contenerizada en el Puerto de Manzanillo (2025 – 2050).



Fuente: Datos estadísticos proporcionados por ASIPONA Manzanillo, 2026

En el escenario base se utilizó una tasa de crecimiento anual compuesta de 3.8%, coherente con un comercio mundial creciendo alrededor de 3.0–3.5% anual y una elasticidad

comercio/PIB consistente con tendencias históricas recientes. El factor acumulado en 25 años bajo esta tasa es aproximadamente 2.57 veces el volumen base, lo que resulta en una proyección cercana a 10.3 millones de TEU anuales al 2050. Bajo esta trayectoria, el sistema más que duplica su escala actual y requiere una expansión estructural significativa, particularmente en frentes de atraque especializados, patios de alta densidad e infraestructura ferroviaria.

En el escenario optimista se adoptó una tasa anual compuesta de 4.8%, asociada a un contexto de nearshoring acelerado, mayor captación de inversión manufacturera y fortalecimiento del rol regional del puerto. El factor acumulado en este caso es aproximadamente 3.23 veces el volumen inicial, lo que conduce a una proyección cercana a 12.9 millones de TEU anuales al horizonte 2050. Este nivel implica una transformación estructural del sistema, con características propias de un hub regional de mayor escala en el Pacífico latinoamericano.

Es importante destacar que la diferencia entre escenarios no es lineal, sino exponencial debido al efecto del crecimiento compuesto. Una variación de apenas 1.8 puntos porcentuales entre el escenario conservador (3.0%) y el optimista (4.8%) genera una diferencia superior a 4.5 millones de TEU anuales hacia 2050. Esta divergencia acumulada justifica la planeación por fases y la necesidad de diseñar infraestructura flexible y escalable.

Desde la perspectiva estratégica, el escenario conservador proyecta un sistema que alcanza aproximadamente 8.4 millones de TEU; el escenario base lo posiciona en el entorno de 10.3 millones; y el escenario optimista lo aproxima a 13 millones de TEU anuales. Estos valores constituyen las referencias cuantitativas para dimensionar capacidad marítima, superficie de patio, requerimientos ferroviarios y número de puertas necesarias en la expansión hacia Cuyutlán.

5.3 Implicaciones de Infraestructura Derivadas de la Proyección de Carga al 2050.

La cuantificación de los tres escenarios de proyección al horizonte 2050 no constituye un ejercicio aislado, sino la base para dimensionar la infraestructura requerida en el sistema portuario Manzanillo–Cuyutlán. La diferencia entre proyectar 8.4 millones, 10.3 millones o 12.9 millones de TEU's anuales no solo implica mayor volumen, sino distintos niveles de escala operativa, configuración física y exigencia tecnológica.

Para efectos de estimación conceptual se parte de parámetros de diseño consistentes con estándares internacionales en terminales de contenedores de alta productividad. Se considera una productividad promedio por grúa STS del orden de 30–35 movimientos por hora, una disponibilidad efectiva de 6,000 a 6,500 horas operativas anuales por equipo, una relación promedio cercana a 1.6 TEU's por movimiento y un factor de utilización objetivo en torno al 65% para evitar saturación estructural. Bajo estos supuestos, una grúa STS puede movilizar aproximadamente entre 300,000 y 350,000 TEU's anuales en condiciones eficientes.

En el escenario conservador, con una demanda proyectada de aproximadamente 8.4 millones de TEU's al año 2050, el sistema requeriría del orden de 24 a 28 grúas STS operativas para sostener el flujo anual con márgenes adecuados de utilización. Si se considera una simultaneidad promedio de tres a cuatro grúas por buque, el número de frentes de atraque especializados necesarios se ubicaría en un rango aproximado de 7 a 9 posiciones activas de gran calado. En términos lineales, esto implica del orden de 2,500 a 3,000 metros lineales de muelle especializado en contenedores, dependiendo de la eslora promedio de las embarcaciones y del nivel de simultaneidad operacional.

El dimensionamiento de patio bajo este escenario parte del inventario promedio. Si se asume un tiempo de permanencia medio de 5 días y un volumen anual de 8.4 millones de TEU's, el inventario promedio diario se ubica en aproximadamente 115,000 TEU's. Considerando un factor de reserva operativo y una utilización objetivo del 70%, el número de posiciones o "slots" requeridos podría situarse en el orden de 160,000 TEU's simultáneos. Con densidades netas de almacenamiento cercanas a 1,000–1,200 TEU's por hectárea en configuraciones RTG de alta eficiencia, el sistema requeriría aproximadamente entre 130 y 160 hectáreas netas de patio especializado.

En el escenario base, con una proyección cercana a 10.3 millones de TEU anuales, la escala del sistema se incrementa de manera significativa. Bajo los mismos parámetros de productividad, el número de grúas STS necesarias podría ubicarse en un rango de 30 a 34 equipos operativos. Esto implicaría entre 9 y 11 frentes de atraque simultáneos, con una longitud total de muelle especializado que podría aproximarse a 3,200–3,800 metros lineales. En este caso, el inventario promedio diario superaría los 140,000 TEU's, lo que obligaría a contar con más de 200,000 posiciones de almacenamiento simultáneo considerando reservas operativas. La superficie neta de patio podría situarse entre 170 y 200 hectáreas, dependiendo del nivel de automatización y de la densidad alcanzable.

El escenario optimista, con una proyección cercana a 12.9 millones de TEU's anuales, implica una transformación estructural del sistema. La demanda anual requeriría entre 38 y 42 grúas STS operativas para mantener niveles de utilización adecuados. El número de frentes simultáneos podría elevarse a 12 o más posiciones de gran calado, con una longitud total de muelle que podría superar los 4,000 metros lineales especializados en contenedores. El inventario promedio diario en patio superaría los 175,000 TEU's, lo que, con factores de seguridad operativa, podría exigir más de 250,000 posiciones simultáneas de almacenamiento. Bajo densidades de diseño avanzadas, la superficie neta de patio podría ubicarse entre 220 y 260 hectáreas.

La dimensión terrestre adquiere relevancia creciente conforme se escala en volumen. En los tres escenarios, la capacidad de puertas y la infraestructura ferroviaria determinan la viabilidad operativa del sistema. En el escenario conservador, el sistema podría operar con un número moderado de carriles de acceso y trenes diarios, siempre que se mantenga una participación ferroviaria creciente cercana al 40%. En el escenario base, el incremento de volumen exige

consolidar una participación ferroviaria superior al 50% para evitar congestión crónica en accesos carreteros. En el escenario optimista, la operación ferroviaria 24/7 se convierte en condición estructural, y el diseño de patios intermodales debe dimensionarse para trenes de gran longitud con atención simultánea.

Estas estimaciones no representan ingeniería de detalle, sino órdenes de magnitud consistentes con estándares internacionales de planeación portuaria. Su propósito es traducir las cifras de proyección en requerimientos físicos tangibles y evidenciar que la diferencia entre escenarios no es únicamente estadística, sino espacial y estructural.

En términos estratégicos, el escenario conservador permite una expansión escalonada que protege la operación actual. El escenario base exige una ampliación integral planificada con anticipación. El escenario optimista, en cambio, requiere decisiones tempranas de inversión para evitar que la restricción de infraestructura limite la captura de mercado.

6.0 CONCLUSIONES Y RECOMENDACIONES ESTRATÉGICAS

6.1 Conclusiones

El análisis de proyección al horizonte 2050 confirma que el sistema portuario Manzanillo–Cuyutlán enfrenta una trayectoria estructural de crecimiento, independientemente del escenario considerado. Aun bajo un supuesto conservador, el volumen anual proyectado implica una duplicación aproximada del movimiento actual, lo que descarta la posibilidad de sostener el crecimiento exclusivamente mediante mejoras operativas marginales dentro del recinto existente.

La diferencia entre escenarios no es lineal, sino exponencial, debido al efecto del crecimiento compuesto. Un diferencial de menos de dos puntos porcentuales en la tasa anual genera una brecha acumulada superior a cuatro millones de TEU's hacia el año 2050. Esta divergencia implica configuraciones físicas sustancialmente distintas en términos de frentes de atraque, superficie de patios y requerimientos intermodales. En consecuencia, la planeación debe ser flexible y escalable, evitando tanto la subinversión como la sobrecapacidad prematura.

El componente contenerizado consolida su carácter dominante dentro del sistema. Incluso considerando la permanencia de graneles y otros tráficos, la presión estructural se concentra en el subsistema de contenedores, particularmente en la interfaz muelle–patio–desalojo. La infraestructura ferroviaria adquiere un papel estratégico crítico en todos los escenarios, pero especialmente en el base y optimista, donde la participación modal elevada se convierte en condición necesaria para evitar congestión crónica.

Desde la perspectiva marítima, el número de frentes de atraque especializados y la longitud total de muelle requerida hacia 2050 superan claramente la capacidad actual del sistema. La expansión en Cuyutlán no constituye únicamente una mejora operativa, sino una evolución estructural del puerto hacia una escala superior.

En términos espaciales, la superficie neta de patios requerida en los escenarios base y optimista confirma que la disponibilidad de suelo logístico de gran escala es un factor determinante. La eficiencia en densidad de almacenamiento puede mitigar parcialmente la presión, pero no sustituye la necesidad de ampliación territorial.

Finalmente, el análisis evidencia que la infraestructura debe concebirse como sistema integrado. El incremento de grúas STS o metros lineales de muelle, sin expansión proporcional de patios y accesos ferroviarios, generaría cuellos de botella desplazados. La capacidad efectiva está determinada por el eslabón más restrictivo de la cadena operativa.

6.2 Recomendaciones estratégicas

La primera recomendación es adoptar un esquema de desarrollo por fases claramente estructurado, vinculado a umbrales de demanda observada. Cada fase debe activarse cuando los indicadores de utilización de muelle, patio y accesos alcancen niveles cercanos al 60%–65%, evitando que el sistema opere de forma prolongada por encima de niveles óptimos.

En segundo término, es indispensable priorizar la infraestructura ferroviaria como eje estructural del crecimiento. El incremento progresivo de la participación modal ferroviaria reduce la presión sobre puertas y vialidades urbanas, mejora la rotación de patios y fortalece la competitividad logística del puerto en su hinterland natural.

Asimismo, se recomienda diseñar los nuevos frentes de atraque bajo criterios de flexibilidad operativa, permitiendo atender embarcaciones de gran eslora y adaptarse a tendencias de aumento en el tamaño promedio de buques. La profundidad de diseño y la resistencia estructural de los muelles deben anticipar la evolución de la flota internacional.

En materia de patios, se recomienda considerar configuraciones de alta densidad y potencial de automatización gradual, de manera que la productividad pueda incrementarse sin necesidad inmediata de expansión territorial adicional. Sin embargo, dicha optimización debe verse como complemento y no como sustituto de la expansión física requerida en escenarios de mayor crecimiento.

Desde el punto de vista financiero y de gestión de riesgo, es recomendable utilizar el escenario base como trayectoria central de planeación, manteniendo el escenario conservador como referencia mínima para estructuración financiera y el optimista como parámetro de estrés superior para diseño conceptual. Este enfoque permite mantener equilibrio entre prudencia y visión estratégica.

Finalmente, se recomienda mantener un sistema continuo de monitoreo de indicadores macroeconómicos, elasticidades comercio/PIB y participación modal, con revisiones periódicas del CAGR efectivo observado. La planeación portuaria a 25 años requiere mecanismos dinámicos de ajuste, más que esquemas rígidos predeterminados.

1.0 INTRODUCCIÓN

La ampliación del Puerto de Manzanillo hacia la Laguna de Cuyutlán constituye un punto de inflexión en la evolución del sistema portuario del Pacífico mexicano. Más que una expansión física, representa la oportunidad de redefinir el modelo operativo bajo el cual el puerto ha crecido durante las últimas décadas.

El contexto actual del transporte marítimo —marcado por megabuques de gran capacidad, mayor concentración de carga por escala, exigencias de descarbonización y mayor integración logística— exige un cambio en la arquitectura funcional del sistema. Las tensiones operativas acumuladas en el recinto histórico evidencian que el crecimiento incremental ya no es suficiente para garantizar competitividad y resiliencia en el largo plazo.

En este marco, el presente informe desarrolla el modelo de desarrollo portuario propuesto para Manzanillo–Cuyutlán, comparando distintas tipologías internacionales y evaluando escenarios estructurales hacia 2050. El objetivo es definir el régimen operativo más adecuado para sostener el liderazgo del puerto y maximizar su capacidad efectiva en un entorno de alta volatilidad.

2.0 OBJETIVOS.

2.1 Objetivo Principal.

El objetivo principal de los servicios descritos en el presente documento es:

- Definir el modelo de desarrollo portuario óptimo para la ampliación del sistema Manzanillo–Cuyutlán, evaluando alternativas estructurales de organización operativa y territorial bajo un enfoque port-led escalable al horizonte 2050.

2.2 Objetivos Particulares.

Los objetivos particulares de los servicios descritos en el presente documento son:

- El documento tiene como finalidad analizar los distintos modelos de desarrollo portuario existentes, evaluar las tensiones operativas actuales del recinto histórico y determinar su impacto sobre la capacidad máxima efectiva del puerto.

- Asimismo, busca desarrollar escenarios de redistribución de carga con la entrada en operación de Cuyutlán, analizar sus implicaciones en términos de resiliencia, elasticidad y competitividad, y establecer lineamientos estratégicos de implementación que permitan evolucionar hacia un sistema portuario integrado, eficiente y sostenible.

3.0 MODELO PORTUARIO DE CUYUTLÁN.

Hacia 2026, la llegada de megabuques a Manzanillo tendrá un importante impacto logístico en el Pacífico mexicano, al modificar la escala operativa del principal puerto del país, la planeación de rutas Asia–México y la presión sobre su hinterland.

Más allá de la expansión de terminales, este cambio responde a una transformación estructural del transporte marítimo global, que se encamina a un modelo de mayor concentración de carga en menos escalas, impulsado por enormes buques que superan los 400 metros de eslora y capacidades cercanas a los 24,000 TEU.

Este cambio no es menor, operar este tipo de naves exige infraestructura especializada, mayor productividad por hora y una coordinación mucho más fina entre terminales, navieras y actores del hinterland; para el Pacífico mexicano, representa un salto de escala que transforma la planeación logística.

3.1 Modelos de Desarrollo Portuario.

El concepto de desarrollo port-led surge en el contexto de la evolución de los sistemas portuarios contemporáneos, donde el puerto deja de ser una infraestructura aislada dedicada exclusivamente a la transferencia marítima de mercancías y pasa a convertirse en el eje articulador del desarrollo logístico, industrial y territorial. Bajo este enfoque, el puerto no solo responde al crecimiento del comercio, sino que lo estructura, lo organiza y lo potencia a través de una integración funcional con plataformas logísticas, parques industriales, corredores intermodales y cadenas de suministro regionales.

En términos técnicos, un modelo port-led implica que la expansión portuaria se diseña de manera integrada con el hinterland, de modo que la infraestructura marítima, los patios, los accesos, la intermodalidad y los nodos logísticos externos operan como un solo sistema. El puerto no es únicamente el punto donde la mercancía cambia de modo de transporte; es el núcleo de una red territorial ampliada. Esta integración permite desacoplar funciones, reducir permanencias, gestionar inventarios fuera del recinto inmediato y elevar la capacidad máxima efectiva del sistema completo.

Para comprender la especificidad del modelo port-led, es necesario contrastarlo con otras clasificaciones tradicionales de puertos, que han predominado históricamente en la literatura y en la práctica institucional.

Tabla 3.1 Comparativa de Modelos de Desarrollo Portuario

DIMENSIÓN DE ANÁLISIS	PUERTO TRADICIONAL / ENCLAVE	PUERTO LANDLORD	PUERTO HUB (TRANSBORDO)	PUERTO GATEWAY	PUERTO INDUSTRIAL	MODELO PORT-LED
Función principal	Transferencia básica buque–tierra	Gestión del suelo con operación privada	Concentración y redistribución marítima	Puerta de entrada al mercado interior	Soporte directo a complejo industrial	Eje estructurador logístico–territorial
Relación con el hinterland	Limitada y reactiva	Variable, depende del operador	Secundaria (predomina conectividad marítima)	Alta conexión comercial	Vinculación productiva específica	Integración sistémica profunda
Enfoque dominante	Infraestructura física interna	Gobernanza institucional	Economías de escala marítimas	Conectividad comercial	Integración vertical industria–puerto	Articulación logística, territorial e industrial
Expansión típica	Más muelle y patio dentro del recinto	Nuevas concesiones o ampliación de áreas	Más posiciones para grandes buques	Mejora de accesos y corredores	Expansión de complejos industriales adyacentes	Desarrollo de nodos externos, intermodalidad y plataformas logísticas
Capacidad máxima efectiva	Depende del espacio físico disponible	Mejora por eficiencia privada	Alta en muelle, limitada en hinterland	Depende de infraestructura terrestre	Asociada al sector industrial dominante	Elevada por desacople funcional y reducción de variabilidad
Gestión de picos operativos	Patio como regulador forzado	Depende de cada terminal	Alta intensidad en muelle	Sensible a evacuación terrestre	Concentrada en ciclos productivos	Amortiguación mediante buffers externos e intermodalidad
Intermodalidad	Complementaria	Variable	Secundaria frente a lo marítimo	Relevante para distribución nacional	Integrada al complejo industrial	Estructural y planificada desde diseño
Diversificación económica	Limitada	Media	Baja (marítimo predominante)	Alta en comercio	Dependiente de sector industrial	Alta y multicliente
Gobernanza	Centralizada o estatal	Separación autoridad–operador	Orientada a competitividad marítima	Coordinación logística regional	Integración empresa–puerto	Gobernanza sistémica multiactor
Impacto territorial	Bajo o concentrado en zona portuaria	Moderado	Limitado al recinto	Expansión hacia corredores	Desarrollo industrial localizado	Transformación regional ampliada
Riesgo sistémico	Alto por concentración espacial	Depende del número de concesiones	Dependiente de flujos marítimos globales	Asociado al mercado interno	Dependiente del ciclo industrial	Reducido por diversificación y desacople
Escalabilidad hacia 2050	Limitada por espacio físico	Moderada	Alta en tráfico marítimo	Alta si hinterland crece	Limitada por sector dominante	Alta por expansión territorial y funcional

Nota: El modelo tradicional concentra funciones dentro del recinto y su crecimiento está limitado por espacio físico. El modelo landlord mejora eficiencia operativa mediante participación privada, pero no necesariamente transforma la relación con el territorio. El puerto hub maximiza conectividad marítima, pero puede depender excesivamente del comercio internacional. El puerto gateway conecta mercados internos, aunque su capacidad depende de infraestructura terrestre. El puerto industrial integra producción específica, pero su diversificación es limitada. El modelo port-led, en cambio, incorpora elementos de todos los anteriores, pero los reorganiza bajo una lógica sistémica. No se limita a expandir infraestructura, sino que rediseña el sistema completo, integrando intermodalidad, plataformas externas, gobernanza coordinada y desarrollo territorial.

En primer lugar, el modelo de puerto tradicional o enclave se caracteriza por su concentración funcional en el recinto portuario. En este esquema, el puerto actúa esencialmente como punto de transferencia entre modos de transporte, con escasa articulación estructural con el territorio circundante. Las funciones de almacenamiento, inspección, consolidación y valor agregado suelen desarrollarse dentro del propio recinto o en áreas adyacentes inmediatas. El hinterland se concibe como espacio pasivo de recepción de carga, no como parte integrada del sistema. En este modelo, el crecimiento del puerto se traduce principalmente en ampliación física del muelle y del patio, sin transformación profunda de la arquitectura logística. La capacidad efectiva depende fuertemente de la eficiencia interna del recinto y de la disponibilidad de espacio físico.

En contraste, el modelo landlord port, que se consolidó en las décadas recientes, introduce una separación institucional entre la autoridad portuaria y los operadores privados. En este esquema, la autoridad administra el suelo y la infraestructura básica, mientras que las terminales son operadas por concesionarios especializados. Este modelo mejora la eficiencia operativa y fomenta inversión privada, pero no necesariamente transforma la relación puerto–territorio. Un puerto puede operar bajo esquema landlord sin adoptar un enfoque port-led, ya que la gobernanza institucional no implica automáticamente integración logística territorial.

Otra clasificación relevante es la del puerto hub o puerto de transbordo. En este modelo, el puerto se especializa en concentrar y redistribuir carga entre rutas marítimas. Su competitividad se basa en economías de escala marítimas, productividad en muelle y conectividad global. El hinterland puede ser limitado o secundario. Aunque un puerto hub puede alcanzar altos volúmenes, su integración territorial no es necesariamente profunda. La lógica dominante es marítima, no logística-territorial. En un modelo port-led, en cambio, el hinterland adquiere protagonismo estratégico y la conectividad terrestre es tan determinante como la marítima.

Existe también la categoría de puerto gateway. Este tipo de puerto actúa como puerta de entrada a un mercado interior amplio y dinámico. Su función principal es conectar comercio internacional con consumo o producción doméstica. El puerto gateway está fuertemente vinculado a su hinterland, pero la integración puede limitarse a corredores de transporte sin una articulación industrial o logística más amplia. El modelo port-led puede considerarse una evolución del concepto gateway, en la medida en que no solo conecta flujos, sino que promueve la instalación de actividades industriales, centros de distribución y cadenas de valor alrededor del sistema portuario.

Una tipología adicional es la del puerto industrial, donde el desarrollo portuario está vinculado directamente a complejos productivos específicos, como petroquímica, siderurgia o manufactura pesada. En este esquema, el puerto se integra verticalmente con plantas industriales adyacentes. El modelo port-led puede incorporar componentes industriales, pero su lógica es más amplia y diversificada; no depende exclusivamente de un sector productivo, sino que busca articular múltiples cadenas logísticas y productivas en torno al puerto.

La diferencia fundamental del enfoque port-led respecto a estas tipologías radica en la escala sistémica. Mientras que en los modelos tradicionales el puerto se expande ampliando infraestructura física dentro de sus límites geográficos, en el modelo port-led la expansión es territorial y funcional. Se crean plataformas externas conectadas por ferrocarril o corredores dedicados, se desarrollan parques industriales orientados a comercio exterior, se implementan sistemas digitales integrados y se coordinan actores públicos y privados bajo una gobernanza sistémica.

Desde el punto de vista operativo, la ventaja del modelo port-led es que permite elevar la capacidad máxima efectiva sin depender exclusivamente de metros lineales de muelle o hectáreas de patio. Al trasladar parte de la regulación logística fuera del recinto inmediato, se reduce la ocupación promedio interna y se mitiga el impacto de los picos operativos. En consecuencia, el sistema puede sostener mayores volúmenes con menor variabilidad y mayor resiliencia.

Desde la perspectiva territorial, el modelo port-led convierte al puerto en motor de desarrollo regional. La infraestructura portuaria no solo atiende flujos existentes, sino que genera nuevas dinámicas económicas, atrayendo inversión, promoviendo especialización industrial y consolidando corredores logísticos integrados.

Sin embargo, el enfoque port-led también implica mayores exigencias de coordinación institucional, planeación ambiental y financiamiento escalonado. Requiere una visión estratégica de largo plazo y una integración efectiva entre infraestructura marítima, transporte terrestre, uso de suelo y política industrial.

En síntesis, mientras que el puerto tradicional se concentra en la transferencia física de mercancías, el puerto landlord optimiza su gobernanza interna, el puerto hub prioriza conectividad marítima y el puerto gateway articula comercio exterior con mercado interior, el modelo port-led integra todas estas dimensiones bajo una lógica sistémica y territorial ampliada. No sustituye necesariamente a las otras clasificaciones, sino que las trasciende al convertir al puerto en el eje estructurador del desarrollo logístico e industrial regional.

Este marco conceptual resulta especialmente pertinente para sistemas en expansión que enfrentan límites físicos en su recinto histórico, como es el caso del sistema Manzanillo–Cuyutlán, donde la ampliación puede optar entre replicar un modelo incremental o evolucionar hacia un esquema port-led plenamente integrado.

Tabla 3.2 Comparativa Cuantitativa de Modelos Portuarios

VARIABLE TÉCNICA	PUERTO TRADICIONAL / ENCLAVE	PUERTO LANDLORD	PUERTO HUB	PUERTO GATEWAY	PUERTO INDUSTRIAL	MODELO PORT-LED
Dependencia de expansión física interna	Muy alta (>80%)	Alta (60–80%)	Alta en muelle	Media–alta	Alta en sector específico	Media (40–60%)
Capacidad máxima efectiva vs nominal	60–70% de nominal	65–75%	70–80%	70–80%	65–75%	80–90%
Nivel sostenible de ocupación de patio	65–70%	70–75%	70–75%	70–75%	65–70%	75–85%
Sensibilidad a picos operativos	Alta	Media–alta	Alta en muelle	Media	Media	Baja–media
Elasticidad de crecimiento a largo plazo	Baja (2–3% anual sostenido)	Moderada (3–4%)	Alta marítima, baja terrestre	Moderada–alta (3–5%)	Moderada	Alta (4–6% sostenido)
Capacidad de desacople muelle–hinterland	Muy baja	Baja–media	Baja	Media	Media	Alta
Participación estructural del ferrocarril	Baja (<25%)	Variable	Secundaria	Media (25–40%)	Media	Alta (>40%)
Tiempo promedio de permanencia (días)	Elevado	Moderado	Variable	Moderado	Variable	Bajo–moderado
Variabilidad operativa (coeficiente relativo)	Alta	Media	Alta en escalas	Media	Media	Baja
Resiliencia ante disrupciones	Baja	Media	Dependiente del comercio global	Media	Sectorial	Alta
Diversificación de fuentes de ingreso	Baja	Media	Baja–media	Media–alta	Baja–media	Alta
Escalabilidad territorial	Limitada al recinto	Limitada	Limitada	Corredores logísticos	Zona industrial	Multinodal
Capacidad proyectada sostenible al 2050 (referencial para sistema tipo Manzanillo)	<8 M TEU	8–9 M TEU	Depende del rol regional	8–10 M TEU	Dependiente de sector	>10–12 M TEU

En la tabla de comparación cuantitativa es posible identificar que la diferencia clave entre modelos no radica únicamente en la capacidad nominal instalada, sino en la proporción de capacidad efectiva utilizable sin degradación operativa. Mientras que en un puerto tradicional la capacidad efectiva suele situarse entre 60% y 70% de la nominal debido a restricciones internas y alta variabilidad, en un modelo port-led esa relación puede elevarse hasta 80% o incluso 90%, debido al desacople funcional y la integración territorial.

Asimismo, el nivel sostenible de ocupación de patio es mayor en un modelo port-led porque el sistema cuenta con buffers externos y plataformas logísticas que permiten redistribuir inventario. Esto reduce el impacto de los picos y aumenta la resiliencia frente a variaciones en programación marítima o terrestre.

La elasticidad de crecimiento a largo plazo es otra variable crítica. En modelos tradicionales, el crecimiento converge rápidamente hacia tasas bajas conforme se aproxima a la saturación física. En cambio, el modelo port-led puede sostener tasas de 4% a 6% anual durante periodos más largos porque la expansión no depende exclusivamente del recinto, sino de la red logística ampliada.

En términos de resiliencia, la integración sistémica y la diversificación territorial reducen la vulnerabilidad ante disrupciones locales. Mientras que un puerto tradicional puede verse afectado significativamente por un evento puntual dentro del recinto, un sistema port-led puede redistribuir flujos entre nodos y plataformas externas.

3.2 El Enfoque de Desarrollo “Port-led”: Concepto, Alcance e Implicaciones

El enfoque de desarrollo port-led se refiere a un modelo en el que el puerto actúa como elemento estructurante del desarrollo logístico, industrial y territorial, y no únicamente como infraestructura de transferencia de carga entre el transporte marítimo y terrestre. Bajo este paradigma, el puerto se concibe como el núcleo de un sistema económico más amplio, capaz de inducir inversiones, reorganizar flujos productivos y generar valor añadido más allá de los límites físicos del recinto portuario.

A diferencia de modelos tradicionales, en los que el puerto respondía de forma pasiva a la demanda del comercio exterior, el desarrollo port-led implica un rol activo del puerto y de su autoridad gestora en la configuración del entorno logístico e industrial. Este rol se expresa a través de la planificación del uso del suelo, la promoción de plataformas logísticas, la coordinación con infraestructura terrestre y la articulación con políticas industriales, energéticas y urbanas.

En términos operativos, el enfoque port-led parte del reconocimiento de que la eficiencia del puerto no depende exclusivamente de lo que ocurre en el muelle, sino del desempeño de toda la cadena logística asociada. En particular, en el tráfico contenerizado, la llegada de megabuques y la concentración de volúmenes por escala generan picos operativos que no pueden ser

gestionados eficazmente si la totalidad de las actividades logísticas se concentran dentro del recinto portuario. El desarrollo de instalaciones externas —patios intermodales, centros de distribución, zonas de consolidación y desconsolidación— permite distribuir los flujos en el tiempo y el espacio, reduciendo la congestión y mejorando la confiabilidad del sistema.

Desde la perspectiva del desarrollo económico, el modelo port-led busca capturar mayor valor añadido del tráfico portuario. En lugar de limitarse a actividades de carga y descarga, el puerto se integra con procesos de almacenamiento, transformación ligera, ensamblaje, etiquetado y distribución, que generan empleo, inversión y encadenamientos productivos en su área de influencia. Este enfoque resulta especialmente relevante en economías abiertas, donde el puerto constituye una puerta de entrada y salida fundamental para insumos y productos terminados.

El desarrollo port-led también tiene una dimensión territorial. La localización de actividades logísticas e industriales asociadas al puerto exige una planificación coordinada del uso del suelo, que evite conflictos con áreas urbanas y ambientales, y que garantice la disponibilidad de espacios adecuados para la expansión futura. En este sentido, el enfoque port-led implica una interacción constante entre autoridades portuarias, gobiernos locales y estatales, y actores privados, con el fin de alinear objetivos de desarrollo económico, ordenamiento territorial y sostenibilidad.

En el ámbito de los graneles y energéticos, el desarrollo port-led se manifiesta en la conformación de complejos logístico-industriales en los que el puerto funciona como nodo de entrada de materias primas y salida de productos transformados. Este modelo permite reducir costos de transporte, mejorar la eficiencia de las cadenas de suministro y fortalecer la competitividad de sectores estratégicos. No obstante, también exige altos estándares de seguridad, control ambiental y gestión de riesgos, dada la naturaleza de los productos manejados.

En el segmento de cruceros, aunque la lógica económica es distinta, el principio port-led se expresa en la integración del puerto con el sistema urbano-turístico. El puerto actúa como punto de articulación entre la actividad marítima y la oferta turística local, lo que requiere inversiones en accesibilidad, gestión de flujos y servicios, así como una coordinación estrecha con autoridades municipales y actores del sector turístico.

Desde el punto de vista institucional, el enfoque port-led transforma el rol de la autoridad portuaria. Más allá de administrar concesiones y operar infraestructura, la autoridad asume funciones de planificación estratégica, facilitación de inversiones y coordinación interinstitucional. Esto incluye la promoción de proyectos logísticos e industriales, la gestión de reservas territoriales, la articulación con proyectos de conectividad terrestre y la integración de criterios ambientales y sociales en el desarrollo portuario.

En síntesis, el desarrollo port-led representa un cambio de paradigma en la concepción del puerto, que pasa de ser un eslabón aislado de la cadena de transporte a convertirse en un motor

del desarrollo logístico, industrial y territorial. Para 2026, este enfoque se consolida como una respuesta estructural a la volatilidad del comercio marítimo, a la concentración operativa derivada de los megabuques y a la necesidad de mejorar la eficiencia y resiliencia de las cadenas logísticas. En el contexto mexicano, el enfoque port-led adquiere especial relevancia como instrumento para fortalecer la competitividad del Sistema Portuario Nacional y maximizar el impacto económico del comercio exterior.

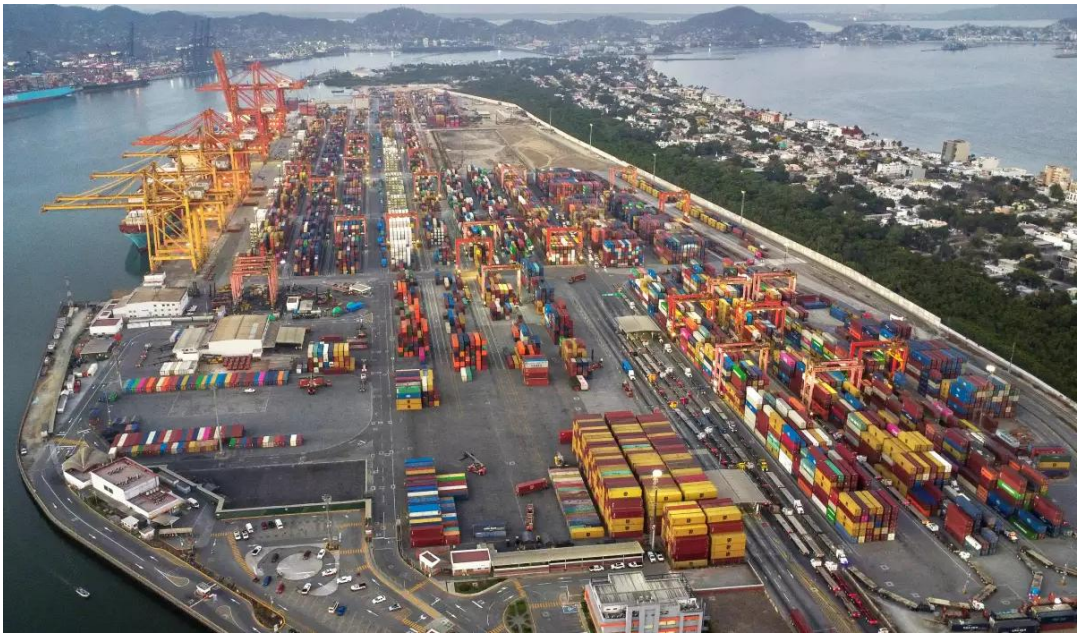
3.3 Modelo Portuario de Manzanillo.

El también llamado "Puente mexicano hacia el Pacífico" funciona como un ecosistema logístico avanzado gracias a la colaboración de 14 empresas operadoras de capital privado y gubernamental, distribuidas en las siguientes áreas de especialización:

1. Manejo de Contenedores (TECs). Es el núcleo del puerto, con dos terminales principales:

    - CONTECON (TEC II): Una de las más dinámicas, con 72 hectáreas, 2 posiciones de atraque y 15 metros de calado.
    - SSA México (TEC I): Posee la mayor longitud de muelle (1,076 metros) con 4 posiciones de atraque.

Figura 3.1 CONTECON (TEC II) en el Puerto de Manzanillo.



Fuente: ASIPONA Manzanillo, 2026

2. Usos múltiples y carga general. Terminales versátiles que gestionan diversos tipos de mercancías:

    - OCUPA (IUM 1) y TIMSA (IUM 2) proporcionan flexibilidad operativa para carga que no es estrictamente contenerizada.

3. Graneles, minerales y construcción. Instalaciones diseñadas para el movimiento masivo de materias primas:

    - Agrícolas: Lideradas por La Junta (descarga 1,000 ton/hora) y Granelera Manzanillo.
    - Minerales y cemento: Terminales especializadas de CEMEX, Apasco y USG (esta última enfocada en yeso con capacidad de 60,000 toneladas).

4. Productos perecederos y líquidos. Infraestructura con cadena de frío y manejo de fluidos:

    - Refrigerados: FRIMAN y Corporación Multimodal atienden carga que requiere control de temperatura.
    - Hidrocarburos y Aceites: Operado por PEMEX para combustibles, además de instalaciones para graneles líquidos como aceites de palma y pescado.

5. Sector Turístico y Pesquero:

    - Terminal Turística: Gestionada por el Gobierno de Colima, permite el atraque simultáneo de dos cruceros tamaño Panamax.
    - MARFRIGO: Especializada en productos del mar y servicios pesqueros.

El Puerto de Manzanillo constituye el principal nodo logístico marítimo del Pacífico mexicano y el mayor puerto en movimiento de contenedores del país. Su relevancia estratégica no es únicamente nacional; es un punto de articulación fundamental del comercio transpacífico, particularmente en las rutas Asia–México y Asia–Norteamérica con distribución hacia el centro y occidente del territorio nacional. Su hinterland natural incluye la región industrial del Bajío, el Valle de México y corredores productivos de alto dinamismo económico.

Desde el punto de vista operativo, Manzanillo es un puerto multipropósito. En 2024 el volumen total de carga manejada superó los 33 millones de toneladas, de las cuales aproximadamente 23.6 millones correspondieron a carga contenerizada. Esto implica que alrededor del 70% del total de toneladas movilizadas en el puerto ya se encuentra asociado al sistema de contenedores. Este dato es estructuralmente relevante, porque confirma que la dinámica portuaria actual está determinada principalmente por el comportamiento del tráfico

contenerizado y no por graneles o energéticos, que históricamente habían sido componentes dominantes en otros puertos.

Figura 3.2 Zona de Influencia del Puerto de Manzanillo.

Fuente: https://tusclasesdecomercioexterior.wordpress.com/, 2026

En términos de TEU's, el puerto alcanzó recientemente niveles cercanos a los 3.9 millones de unidades anuales. La evolución histórica de la última década muestra una tendencia de crecimiento sostenido, interrumpida únicamente por fluctuaciones coyunturales asociadas a ciclos económicos o disrupciones logísticas globales. Sin embargo, la trayectoria estructural es claramente ascendente. Si se observa el periodo 2016–2024, el sistema contenerizado muestra una expansión significativa tanto en volumen absoluto como en intensidad operativa, acompañada de un aumento en el tamaño promedio de los buques que arriban al puerto.

La estructura operativa actual del sistema de contenedores se concentra principalmente en tres terminales, dos de las cuales absorben de manera recurrente entre el 70% y el 80% del total de TEU's movilizados. Esta concentración implica que el desempeño sistémico del puerto depende en gran medida de la estabilidad operativa de un número reducido de nodos. Cuando el volumen total anual se aproxima a los cuatro millones de TEU's, esta concentración adquiere una dimensión estructural: cualquier variación operativa en una de estas terminales tiene efectos multiplicadores sobre el sistema completo.

El crecimiento del tráfico contenerizado no ha sido únicamente cuantitativo, sino cualitativo. En los últimos años se ha observado un incremento en el tamaño promedio de los buques que escalan en Manzanillo. Esta tendencia responde a economías de escala marítimas globales. Los buques de mayor capacidad reducen costos unitarios por TEU's, pero generan descargas más concentradas en cada arribo. El efecto sistémico es una intensificación de los picos

operativos. En lugar de recibir múltiples buques medianos con descargas distribuidas en el tiempo, el puerto recibe menos escalas, pero con mayores volúmenes por evento.

Este fenómeno tiene implicaciones directas sobre la gestión de patios. El patio de contenedores cumple simultáneamente funciones de tránsito y regulación. Cuando el volumen anual era menor y las descargas estaban más distribuidas, la ocupación promedio del patio podía mantenerse dentro de rangos operativamente eficientes. Sin embargo, conforme el volumen total se aproxima a los cuatro millones de TEU's y las descargas se concentran en ventanas temporales más cortas, la ocupación promedio se incrementa y, lo que es más relevante, la ocupación en horas pico supera niveles óptimos. En términos de teoría de operaciones, cuando la ocupación promedio se aproxima al 70%–75% de la capacidad efectiva, el sistema comienza a perder flexibilidad y la productividad marginal disminuye de forma no lineal.

En Manzanillo, la saturación no se manifiesta necesariamente como colapso permanente, sino como pérdida progresiva de holgura. Esto se traduce en mayor permanencia promedio de los contenedores dentro del recinto, mayor número de movimientos internos de reacomodo y mayor sensibilidad a retrasos en la evacuación terrestre. La permanencia promedio es un indicador crítico, porque determina la rotación del inventario. Si la permanencia aumenta, el patio se convierte en almacenamiento forzado, reduciendo la capacidad efectiva sin que la infraestructura física cambie.

El componente terrestre es otro elemento estructural de la problemática. Aunque el puerto cuenta con conectividad ferroviaria, una proporción significativa de la evacuación sigue dependiendo del transporte por carretera. El crecimiento del volumen anual implica mayor flujo de camiones en accesos que, en parte, interactúan con la estructura urbana circundante. La capacidad de los accesos terrestres no ha crecido al mismo ritmo que la productividad marítima. En términos técnicos, se ha generado un desfase entre la capacidad de descarga en muelle y la capacidad de evacuación hacia el hinterland.

Este desfase produce un efecto acumulativo. Si el puerto puede descargar un volumen elevado en pocas horas gracias a grúas pórtico de alta productividad, pero la salida terrestre no puede absorber ese volumen con la misma velocidad, el resultado es acumulación en patio. A medida que el volumen anual aumenta, la probabilidad de que estos desfases coincidan con eventos externos —como congestión urbana, condiciones climáticas o interrupciones ferroviarias— también aumenta.

La concentración del volumen en pocas terminales incrementa además el riesgo sistémico. Con volúmenes anuales cercanos a los cuatro millones de TEU's, una disrupción temporal en una terminal dominante puede afectar cientos de miles de TEU's en términos de programación acumulada. Esto reduce la resiliencia global del sistema. Desde una perspectiva estadística, la variabilidad es más crítica que el promedio. Un puerto puede manejar grandes volúmenes

promedio si la variabilidad es baja; cuando la variabilidad aumenta, el desempeño se vuelve menos predecible y los costos logísticos totales se incrementan.

Otro elemento que contribuye a la complejidad operativa es la coexistencia de tráficos multipropósito. Aunque el contenedor representa aproximadamente el 70% del total de toneladas manejadas, el puerto sigue atendiendo granel mineral, granel agrícola, energéticos y carga general. Estos flujos requieren áreas específicas, condiciones de seguridad diferenciadas y coordinación en navegación. La coexistencia no es en sí problemática, pero reduce el margen de maniobra espacial en un recinto ya altamente utilizado.

La suma de estos factores configura una problemática estructural que puede describirse como madurez avanzada del recinto histórico. El puerto ha demostrado capacidad para crecer hasta niveles cercanos a los cuatro millones de TEU’s, pero lo ha hecho utilizando progresivamente su margen operativo. La capacidad nominal ha aumentado mediante inversiones en equipamiento y mejoras de productividad, pero la capacidad máxima efectiva se encuentra condicionada por la arquitectura sistémica vigente.

En síntesis, el Puerto de Manzanillo enfrenta una situación donde el crecimiento del tráfico contenerizado ha generado intensificación de picos operativos, aumento de ocupación promedio de patios, desfase entre productividad marítima y evacuación terrestre, concentración de riesgo en pocas terminales y aumento de variabilidad logística. No se trata de una crisis estructural, sino de una transición hacia un nuevo umbral operativo donde la expansión física, por sí sola, puede resultar insuficiente si no se acompaña de una reconfiguración funcional del sistema.

Esta situación es precisamente la que justifica la ampliación hacia la Laguna de Cuyutlán y la discusión de los escenarios de transformación operativa hacia 2050.

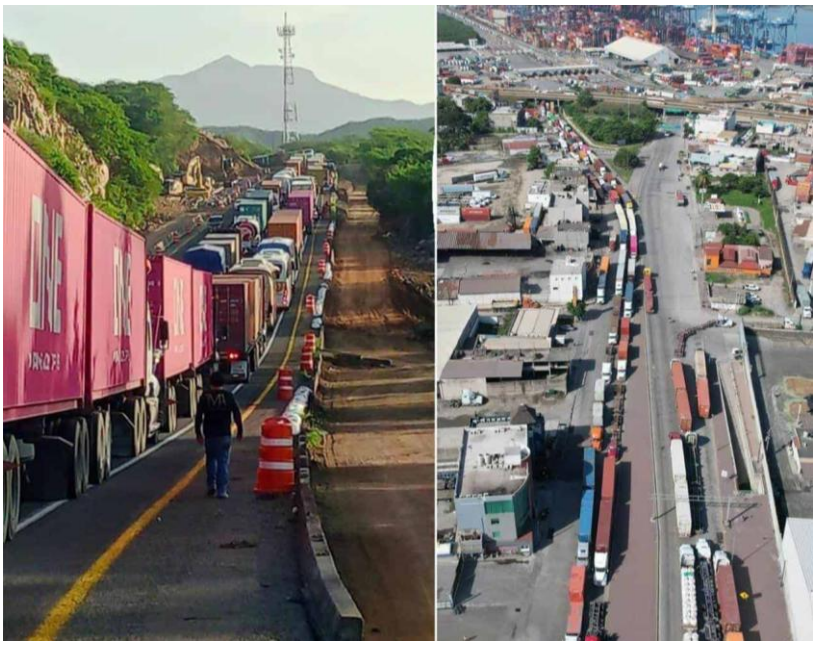
3.4 Las Tensiones Operativas Actuales como Punto de Inflexión del Modelo Portuario de Manzanillo.

La situación operativa actual del Puerto de Manzanillo debe interpretarse como el resultado lógico de una trayectoria de éxito sostenido, más que como una disfunción del sistema. Durante más de tres décadas, el puerto ha absorbido volúmenes crecientes de carga, adaptándose progresivamente a los cambios tecnológicos del transporte marítimo, a la expansión del comercio internacional y a la creciente integración de México en las cadenas globales de valor. Sin embargo, esta misma trayectoria ha conducido al puerto a un punto de inflexión, en el cual los límites físicos, operativos y territoriales del recinto actual se hacen evidentes.

La evolución histórica muestra que el crecimiento no ha sido solo cuantitativo, sino también cualitativo. El predominio del tráfico contenerizado, la mayor concentración de escalas navieras y la creciente complejidad logística han modificado la naturaleza de la operación portuaria. En este nuevo contexto, el puerto ya no funciona únicamente como un punto de

transferencia modal, sino como un nodo logístico de alta intensidad, donde convergen flujos marítimos, terrestres, regulatorios y productivos. Es precisamente esta convergencia la que genera las tensiones operativas actuales.

Figura 3.3 Congestión de Vialidades en el Puerto de Manzanillo.



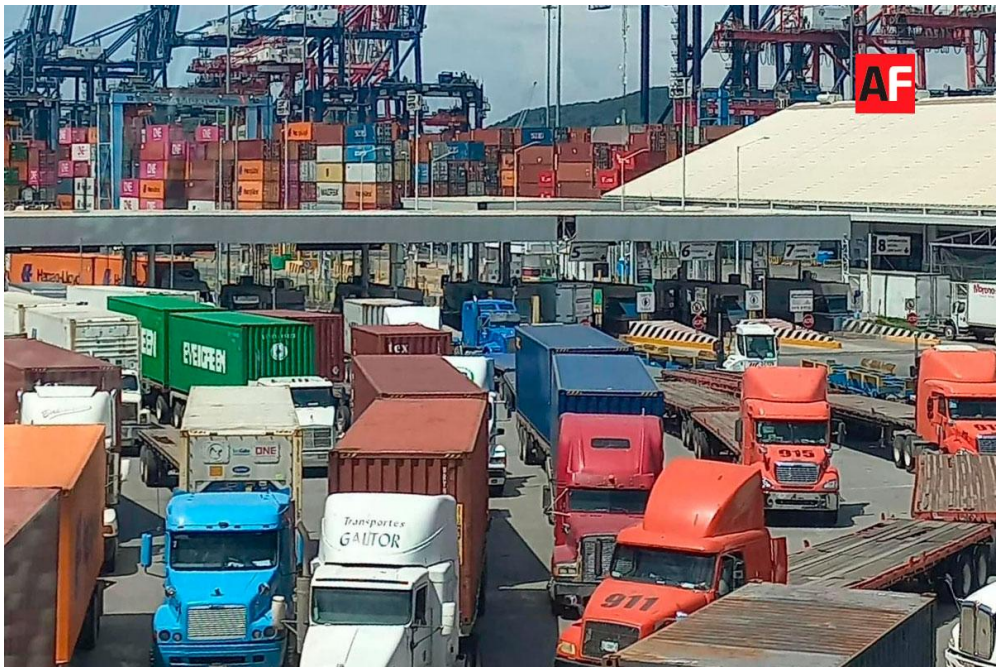
Fuente: Agencia Reforma.

3.4.1 Congestión y pérdida de holgura operativa.

Uno de los síntomas más visibles de este punto de inflexión es la congestión recurrente, que se manifiesta en distintos subsistemas del puerto. A diferencia de etapas anteriores, en las que la congestión aparecía de manera episódica, hoy se presenta como una condición latente, que puede activarse rápidamente ante cualquier perturbación del sistema. Esta situación refleja una pérdida progresiva de holgura operativa, entendida como la capacidad del puerto para absorber variaciones de demanda sin degradar significativamente su desempeño.

Desde una perspectiva técnica, la holgura es un atributo esencial de los sistemas logísticos complejos. Su reducción implica que el puerto opera cada vez más cerca de su capacidad máxima efectiva, lo que incrementa la probabilidad de fallas en cascada. En Manzanillo, esta pérdida de holgura se traduce en mayores tiempos de espera, menor previsibilidad operativa y un uso intensivo del espacio disponible, especialmente en patios y áreas de apoyo.

Figura 3.4 Congestión y Pérdida Operativa en el Puerto de Manzanillo.



Fuente: https://www.afmedios.com/.

3.4.2 Intensificación de picos operativos y presión sistémica

El patrón operativo contemporáneo, dominado por buques portacontenedores de gran tamaño, ha introducido una nueva dimensión de presión sobre el sistema: la intensificación de los picos operativos. La carga que antes se distribuía en múltiples arribos ahora se concentra en ventanas temporales más cortas, lo que exige una capacidad de respuesta simultánea en muelle, patio y accesos terrestres.

Estos picos no solo afectan la productividad de las terminales, sino que ponen a prueba la coordinación entre los distintos actores del sistema portuario y logístico. Cuando la infraestructura y la organización espacial no están diseñadas para amortiguar estas concentraciones, el resultado es una mayor fricción operativa y una creciente dependencia de medidas reactivas, en lugar de soluciones estructurales.

3.4.3 Saturación funcional de patios y espacios operativos

La evolución histórica del manejo de contenedores ha llevado a una saturación funcional de los patios, que hoy operan con niveles de ocupación elevados y con una flexibilidad cada vez

menor. En estas condiciones, los patios dejan de cumplir su función como espacios de regulación y se convierten en cuellos de botella, donde cualquier retraso en la evacuación de carga se traduce rápidamente en congestión.

Figura 3.5 Saturación de Patios en el Puerto de Manzanillo.

Fuente: https://www.meganoticias.mx/.

Desde el punto de vista del diseño portuario, esta situación es indicativa de un desfase entre el crecimiento del flujo y la capacidad espacial del sistema. La intensificación de los movimientos improductivos, el aumento del reacomodo interno y la dificultad para segregar tráficos son señales claras de que el modelo actual ha alcanzado sus límites de eficiencia.

3.4.4 Accesos terrestres y desconexión espacial del sistema logístico

Otra tensión crítica se manifiesta en la relación entre el puerto y su hinterland. El crecimiento histórico de los volúmenes no ha sido acompañado por una expansión equivalente de los accesos terrestres ni por una redistribución espacial de las funciones logísticas. Como resultado, el puerto concentra dentro de su recinto actividades que podrían realizarse de manera más eficiente en espacios externos, generando una presión adicional sobre los accesos y sobre la interfaz puerto–ciudad.

Esta desconexión espacial limita la capacidad del sistema para evacuar carga de manera fluida, especialmente en periodos de alta demanda. Además, incrementa la vulnerabilidad del puerto frente a disrupciones externas, como congestionamientos urbanos, restricciones de horario o incidencias en la red carretera y ferroviaria.

3.4.5 Complejidad del modelo multipropósito y conflictos de uso

La coexistencia de múltiples tipos de carga —contenedores, graneles, carga general y energéticos— en un espacio portuario limitado añade una capa adicional de complejidad. Si bien esta diversidad ha sido históricamente una fortaleza, en el contexto actual se traduce en conflictos de uso del espacio, restricciones operativas y mayores exigencias de seguridad y control ambiental.

La evolución histórica demuestra que estos tráficos no desaparecen ni se sustituyen entre sí; por el contrario, tienden a coexistir y a crecer de manera asincrónica. Esta realidad refuerza la necesidad de una segregación funcional y espacial más clara, que el recinto actual ya no puede ofrecer sin comprometer la eficiencia global del sistema.

3.4.6 Reducción de la resiliencia y aumento del riesgo sistémico

La suma de estas tensiones tiene un efecto directo sobre la resiliencia operativa del puerto. Un sistema con márgenes reducidos, alta concentración operativa y limitada flexibilidad espacial es más vulnerable a eventos externos, ya sean económicos, logísticos, climáticos o regulatorios. En este contexto, la continuidad del servicio portuario depende cada vez más de la ausencia de perturbaciones, una condición difícil de garantizar en el entorno actual del comercio marítimo internacional.

Desde una perspectiva estratégica, esta reducción de la resiliencia representa un riesgo sistémico para el comercio exterior mexicano, dado el peso de Manzanillo en la estructura logística nacional. La gestión de este riesgo no puede basarse únicamente en mejoras incrementales dentro del recinto existente.

3.4.7 La ampliación y el enfoque port-led como respuesta estructural

En este punto de inflexión, la ampliación hacia la Laguna de Cuyutlán y la adopción de un enfoque port-led emergen no como una opción discrecional, sino como una respuesta estructural a las tensiones acumuladas. El enfoque port-led propone una reconfiguración del sistema portuario que trasciende los límites del recinto físico, integrando plataformas logísticas externas, corredores intermodales y actividades de valor añadido en una lógica territorial ampliada.

Este cambio de paradigma permite:

- Recuperar holgura operativa mediante la redistribución espacial de funciones.
- Amortiguar picos operativos desplazando actividades no críticas fuera del muelle.
- Reducir la presión sobre patios y accesos internos.
- Incrementar la resiliencia del sistema frente a la volatilidad del mercado.
- Alinear el crecimiento portuario con el desarrollo logístico e industrial regional.

3.4.8 Implicación para la planeación estratégica

La lectura integrada de la evolución histórica y de las tensiones operativas actuales conduce a una conclusión clara: el modelo portuario vigente ha cumplido su ciclo de eficiencia. Continuar expandiendo volúmenes bajo el mismo esquema espacial y operativo incrementaría exponencialmente los riesgos y los costos de operación, tanto para el puerto como para las cadenas logísticas que dependen de él.

En este sentido, la ampliación hacia Cuyutlán y la transición hacia un modelo port-led no deben entenderse como proyectos aislados, sino como la siguiente etapa natural en la evolución del Puerto de Manzanillo, orientada a sostener su liderazgo nacional, mejorar su desempeño sistémico y asegurar su viabilidad de largo plazo.

3.5 Implicaciones de la Estructura de las Terminales Actuales Sobre la Capacidad Máxima Efectiva del Puerto de Manzanillo

La estructura actual de las terminales de contenedores del Puerto de Manzanillo condiciona de manera directa la capacidad máxima efectiva del sistema portuario, entendida no como la suma teórica de capacidades individuales de muelle o patio, sino como el volumen máximo de TEU’s que el puerto puede manejar de forma continua, confiable y con niveles aceptables de servicio. Esta distinción es fundamental para la planeación estratégica, ya que un puerto puede disponer de infraestructura suficiente en términos nominales y, aun así, enfrentar restricciones operativas severas que limiten su desempeño real.

3.5.1 Concentración de volumen y riesgo sistémico

La distribución del manejo de TEU’s entre las terminales muestra una alta concentración operativa, donde dos terminales —SSA Marine México y CONTECON Manzanillo— procesan de manera conjunta entre el 70% y el 80% del total del puerto. Este patrón, común en puertos líderes a nivel internacional, tiene implicaciones profundas sobre la capacidad efectiva.

En un sistema tan concentrado, cualquier limitación en una de estas terminales se traduce rápidamente en una restricción sistémica. La capacidad efectiva del puerto queda, en la práctica, determinada por el desempeño del subconjunto más cargado del sistema, no por el promedio. Así, incluso si una terminal opera con holgura relativa, la saturación de otra puede generar congestión generalizada, redistribución forzada de flujos y pérdida de eficiencia global.

3.5.2 Capacidad de muelle versus capacidad de patio

Uno de los desajustes estructurales más relevantes en la configuración actual es la diferencia entre la capacidad de atención en muelle y la capacidad de regulación en patio. Las

terminales líderes han invertido de manera significativa en grúas pórtico, equipamiento de alta productividad y profundidades adecuadas para buques de gran tamaño, lo que eleva la capacidad teórica de transferencia muelle–buque.

Sin embargo, esta capacidad de muelle no siempre encuentra un respaldo equivalente en patios suficientemente amplios y flexibles. A medida que los volúmenes crecen y se intensifican los picos operativos, los patios se convierten en el principal cuello de botella del sistema. En términos de capacidad efectiva, el puerto queda limitado no por la velocidad de descarga o carga de los buques, sino por la capacidad de almacenar, ordenar y evacuar los contenedores en tierra sin generar congestión interna.

3.5.3 Efecto de los picos operativos en la capacidad efectiva

La creciente utilización de buques portacontenedores de gran tamaño introduce un patrón operativo caracterizado por picos intensos y concentrados en el tiempo. Desde la perspectiva de capacidad efectiva, estos picos reducen el volumen anual que el sistema puede manejar de manera estable, aun cuando el promedio anual de utilización parezca razonable.

En un escenario con picos pronunciados, el sistema debe dimensionarse para atender el máximo, no el promedio. Cuando la infraestructura y la organización espacial no permiten absorber estos picos sin degradación del servicio, la capacidad efectiva se reduce. En Manzanillo, la concentración de picos en las terminales líderes implica que el margen operativo se consume rápidamente, elevando los tiempos de espera y reduciendo la confiabilidad del sistema.

3.5.4 Interdependencia con accesos y evacuación terrestre

La capacidad máxima efectiva del puerto no se define exclusivamente dentro del recinto portuario. La estructura terminal actual genera una alta dependencia de la evacuación terrestre, tanto carretera como ferroviaria, para liberar patios y sostener la rotación de contenedores.

Cuando los accesos y corredores no crecen al mismo ritmo que el volumen contenerizado, la evacuación se ralentiza y los patios pierden su función reguladora. En este contexto, la capacidad efectiva del puerto se ve limitada por factores externos al muelle, como la saturación de accesos urbanos, la disponibilidad de ventanas ferroviarias o la coordinación con centros logísticos externos.

3.5.5 Limitaciones derivadas del modelo multipropósito

La coexistencia de tráficos multipropósito dentro del mismo recinto introduce restricciones adicionales sobre la capacidad efectiva. Aunque las terminales contenerizadas están claramente delimitadas, comparten accesos, servicios comunes y, en algunos casos, interfaces espaciales con terminales de graneles y energéticos.

Esta convivencia obliga a establecer restricciones operativas y de seguridad que reducen la flexibilidad del sistema. Desde la óptica de la capacidad efectiva, cada restricción adicional —horarios, segregación de flujos, zonas de seguridad— actúa como un factor de reducción del volumen máximo sostenible, especialmente en periodos de alta demanda.

3.5.6 La capacidad efectiva como función del sistema, no de terminales aisladas

El análisis de la estructura terminal actual confirma que la capacidad máxima efectiva del Puerto de Manzanillo es una propiedad emergente del sistema completo, no la suma aritmética de capacidades individuales. La concentración de volumen, la saturación de patios, la dependencia de accesos externos y la intensificación de picos operativos interactúan entre sí, definiendo un techo operativo que se alcanza antes de que la infraestructura esté físicamente llena.

En términos prácticos, esto significa que:

a. El puerto puede alcanzar niveles de utilización que parecen aceptables en promedio anual, pero que son insostenibles en la operación diaria.

b. Incrementos marginales de demanda pueden generar efectos desproporcionados sobre la congestión y el nivel de servicio.

c. Las mejoras puntuales dentro de una terminal tienen rendimientos decrecientes si no se acompañan de ajustes sistémicos.

La estructura de las terminales actuales impone un límite claro al crecimiento sostenible del puerto dentro del recinto existente. Superar este límite mediante optimizaciones internas implica costos crecientes y beneficios marginales. Desde una perspectiva estratégica, esto refuerza la necesidad de expandir la capacidad efectiva, no solo la capacidad física, mediante una reconfiguración del sistema portuario.

La ampliación hacia la Laguna de Cuyutlán, concebida bajo un enfoque port-led, ofrece precisamente la posibilidad de romper este techo operativo, redistribuyendo flujos, creando nuevos espacios de regulación y desconectando el crecimiento del volumen de las restricciones del recinto actual. Al incorporar nuevas terminales, patios externos y corredores logísticos integrados, el sistema puede recuperar holgura y elevar su capacidad máxima efectiva de manera estructural.

Las proyecciones de carga para el periodo 2026–2050 deben interpretarse a la luz de estas implicaciones. Sin una modificación sustantiva de la estructura terminal y del modelo operativo, el crecimiento tenderá a aproximarse rápidamente a la capacidad máxima efectiva actual, generando congestión y pérdida de competitividad. En cambio, la expansión y la transición hacia un modelo

port-led permiten redefinir ese límite, habilitando escenarios de crecimiento sostenido que sean compatibles con niveles adecuados de servicio y resiliencia operativa.

3.6 Redistribución de la Participación de TEU's con la Entrada de la Ampliación en la Laguna de Cuyutlán.

La entrada en operación de las nuevas terminales especializadas de contenedores en la Laguna de Cuyutlán no debe interpretarse como un simple aumento aritmético de capacidad, sino como un reordenamiento estructural del sistema contenerizado del Puerto de Manzanillo. En la práctica, las nuevas terminales modifican los equilibrios operativos existentes, redistribuye flujos entre terminales y redefine la capacidad máxima efectiva del puerto en su conjunto.

La forma en que esta redistribución se materializa depende de decisiones estratégicas, tanto del regulador portuario como de los operadores, y del grado en que la ampliación se inserte en un modelo port-led plenamente funcional. Por ello, la redistribución de TEU´s debe analizarse mediante escenarios, no como un resultado único e inevitable.

Para la planeación de la ampliación del puerto de Manzanillo en la Laguna de Cuyutlán se han planteado tres escenarios, los cuales no corresponden simplemente a "niveles de crecimiento distintos". Corresponden a tres regímenes operativos diferentes del sistema portuario Manzanillo–Cuyutlán, es decir, a tres formas estructuralmente distintas de organizar la infraestructura, la logística y la relación puerto–territorio hacia 2050.

Los tres escenarios propuestos corresponden a tres niveles de transformación del sistema:

- El conservador corresponde a crecimiento en escala sin cambio de arquitectura.
- El central corresponde a cambio de arquitectura sin cambio radical de centralidad.
- El alto corresponde a cambio de arquitectura y cambio de centralidad.

En términos de teoría de sistemas logísticos, representan tres estados distintos del régimen operativo:

- Sistema ampliado.
- Sistema reorganizado.
- Sistema redefinido.

Y esa diferencia es la que explica por qué las proyecciones al 2050 divergen en capacidad efectiva, elasticidad de crecimiento y resiliencia.

A continuación, se describe cada escenario de desarrollo.

3.6.1 Escenario Conservador – Expansión incremental sin transformación sistémica

El escenario conservador representa una trayectoria de crecimiento sostenido del sistema portuario Manzanillo–Cuyutlán basada principalmente en la ampliación de infraestructura física, pero sin una reconfiguración profunda de la arquitectura logística y territorial. En este contexto, la expansión hacia la Laguna de Cuyutlán se materializa como una respuesta a la presión acumulada sobre el recinto histórico, pero su función es esencialmente incremental. La nueva infraestructura aumenta la capacidad nominal disponible, reduce parcialmente la congestión inmediata y permite absorber crecimiento adicional en el corto y mediano plazo, aunque sin modificar de manera estructural la lógica operativa del sistema.

En este escenario, el puerto continúa operando bajo una configuración en la que el recinto portuario concentra simultáneamente funciones de transferencia marítima, regulación de inventario y gestión logística inmediata. El aumento de muelles y patios en Cuyutlán proporciona un alivio operativo relevante, especialmente en momentos de alta demanda o durante la atención de buques de mayor tamaño. Sin embargo, la expansión no se acompaña de una transformación integral de los accesos terrestres, de la intermodalidad ferroviaria ni de la integración plena con plataformas logísticas externas. En consecuencia, la capacidad máxima efectiva del sistema crece en menor proporción que su capacidad nominal.

Desde el punto de vista operativo, el escenario conservador supone que la redistribución de servicios entre terminales es limitada. Las terminales dominantes del recinto actual mantienen la mayor parte de sus contratos y servicios históricos, mientras que la nueva terminal en Cuyutlán absorbe principalmente crecimiento incremental y algunos flujos adicionales asociados a nuevas rutas o ajustes comerciales. Esta dinámica reduce parcialmente la concentración de riesgo, pero no altera de manera significativa la dependencia sistémica de un número reducido de nodos.

El comportamiento de los picos operativos en este escenario muestra una mejora relativa respecto a la situación actual, pero no una transformación estructural. La capacidad adicional permite absorber eventos de alta intensidad sin colapsos inmediatos, aunque el sistema sigue siendo sensible a la coincidencia de factores como arribos concentrados, retrasos ferroviarios o congestión en accesos carreteros. El patio continúa funcionando como regulador forzado del sistema, y la permanencia promedio de contenedores disminuye de forma marginal, pero no sustantiva.

En términos de crecimiento, el escenario conservador es coherente con tasas anuales moderadas en el largo plazo. La trayectoria hacia 2050 converge hacia un rango aproximado de cinco a siete millones de TEU´s anuales, cifra que refleja un crecimiento sostenido respecto a los niveles actuales cercanos a cuatro millones de TEU´s, pero que también evidencia una convergencia gradual hacia límites estructurales del sistema ampliado. El crecimiento es real y

significativo, pero la elasticidad del sistema disminuye conforme se aproxima nuevamente a umbrales elevados de utilización.

La resiliencia operativa bajo este escenario mejora respecto a la situación previa a la expansión, aunque no alcanza niveles estructurales altos. La vulnerabilidad ante disrupciones locales o variabilidad en los accesos terrestres persiste, ya que la arquitectura logística continúa estrechamente acoplada entre muelle, patio y su hinterland. La intermodalidad ferroviaria avanza de manera progresiva, pero no se convierte en el eje dominante de evacuación. El transporte carretero sigue siendo determinante en la dinámica diaria del puerto, manteniendo cierta exposición a congestión urbana y fluctuaciones en tiempos de retiro.

Desde la perspectiva estratégica, el escenario conservador ofrece estabilidad y prudencia. Reduce el riesgo de saturación inmediata y permite sostener el liderazgo nacional del puerto en el Pacífico mexicano. No obstante, su alcance competitivo en el ámbito regional ampliado es limitado. El sistema ampliado continúa operando con una lógica de recinto predominante, donde el crecimiento adicional requiere constantemente nuevas expansiones físicas para mantener márgenes de operación adecuados.

En síntesis, el escenario conservador describe un puerto que crece sin cambiar de régimen operativo. La infraestructura se expande, la capacidad nominal aumenta y el volumen total manejado se incrementa de manera sostenida. Sin embargo, la arquitectura sistémica permanece esencialmente intacta, lo que implica que los desafíos estructurales asociados a concentración, variabilidad y dependencia de accesos terrestres no desaparecen, sino que se desplazan a un umbral superior. Es un escenario técnicamente viable y financieramente prudente, pero estructuralmente limitado en su capacidad de transformación profunda hacia 2050.

3.6.2 Escenario Central – Transformación funcional del sistema bajo un modelo port-led maduro

El escenario central representa una trayectoria de evolución estructural del sistema portuario Manzanillo–Cuyutlán en la cual la ampliación hacia la Laguna de Cuyutlán no se limita a incrementar capacidad física, sino que se convierte en el punto de partida para una reconfiguración funcional del sistema completo. En este contexto, el crecimiento proyectado hacia 2050 no depende únicamente de la incorporación de nuevos muelles y patios, sino de la transformación de la arquitectura operativa que articula el puerto con su hinterland.

A diferencia del escenario conservador, en el cual la expansión es esencialmente incremental, el escenario central supone que la nueva infraestructura se integra bajo una lógica port-led madura. Esto implica que el puerto deja de operar como un recinto concentrado y evoluciona hacia un sistema logístico ampliado, donde las funciones de transferencia marítima, regulación de inventario y distribución terrestre se desacoplan parcialmente mediante la incorporación de nodos externos, intermodalidad estructural y coordinación sistémica.

En este escenario, la terminal en Cuyutlán asume un papel redistribuidor. No se limita a captar crecimiento marginal, sino que absorbe parte de los flujos de mayor intensidad operativa, particularmente aquellos asociados a megabuques y descargas concentradas. La redistribución funcional reduce la presión estructural sobre las terminales históricas del recinto actual, estabilizando sus niveles de utilización y disminuyendo la probabilidad de congestión recurrente. El sistema pasa de un esquema altamente concentrado en dos terminales dominantes a un modelo tripolar más equilibrado, donde ninguna instalación individual determina por sí sola el desempeño global.

El elemento técnico central de este escenario es el desacople entre muelle y el hinterland. En la configuración tradicional, la capacidad del puerto está fuertemente condicionada por la velocidad con la que los contenedores pueden salir del recinto. En el modelo central, parte de la regulación logística se traslada hacia plataformas externas conectadas por corredores dedicados y, de manera creciente, por intermodalidad ferroviaria. Estas plataformas funcionan como buffers territoriales que absorben inventario sin comprometer la rotación interna del patio portuario. Como resultado, la ocupación promedio del patio interno se mantiene dentro de rangos sostenibles incluso en periodos de alta demanda.

La intermodalidad adquiere en este escenario un carácter estructural. El ferrocarril no opera únicamente como complemento del transporte carretero, sino como mecanismo clave para evacuar volúmenes significativos de manera programada. La coordinación de ventanas ferroviarias con arribos marítimos reduce la acumulación en patio y disminuye la variabilidad asociada a picos de descarga. La carretera continúa desempeñando un papel relevante, pero su participación se gestiona mediante sistemas de citas y control de flujo que reducen concentraciones temporales en accesos.

Desde la perspectiva de capacidad máxima efectiva, el escenario central eleva el techo operativo del sistema no solo por expansión física, sino por mejora en eficiencia sistémica. La reducción de variabilidad, la disminución en permanencia promedio de contenedores y la mejor distribución de flujos permiten operar con niveles de utilización más altos sin degradación significativa del rendimiento. En términos prácticos, el sistema puede sostener volúmenes cercanos a siete o diez millones de TEU’s hacia 2050 con menor riesgo de congestión estructural.

La resiliencia operativa en este escenario aumenta de manera significativa. La redistribución de servicios reduce la concentración de riesgo, mientras que la existencia de nodos logísticos externos ofrece alternativas ante disrupciones puntuales. El sistema deja de depender exclusivamente del recinto histórico y se convierte en una red funcional ampliada. Esta estructura permite absorber contingencias climáticas, retrasos en programación marítima o interrupciones parciales en accesos sin que el impacto se propague de manera sistémica.

Desde el punto de vista estratégico, el escenario central equilibra ambición y factibilidad. No requiere una reconfiguración geográfica radical ni inversiones desproporcionadas, pero sí exige coordinación institucional, planeación territorial integrada y compromiso sostenido con la intermodalidad y la digitalización logística. Es un escenario que transforma sin sobreexponerse, permitiendo que el sistema evolucione de manera progresiva hacia mayores niveles de competitividad regional.

En términos económicos, la elasticidad de crecimiento bajo este modelo es superior a la del escenario conservador. La integración port-led amplía la capacidad del sistema para captar nuevos flujos comerciales, atraer servicios marítimos adicionales y consolidar su papel como puerta estratégica del comercio transpacífico. La competitividad no se basa únicamente en productividad de muelle, sino en confiabilidad logística integral.

En síntesis, el escenario central describe un sistema que cambia de régimen operativo. La expansión hacia Cuyutlán se convierte en instrumento de reorganización estructural, permitiendo desacoplar funciones, redistribuir riesgos y elevar la capacidad efectiva de manera sostenida. El puerto deja de crecer únicamente en escala y comienza a crecer en arquitectura. Este escenario ofrece una trayectoria sostenible hacia 2050, posicionando al sistema Manzanillo–Cuyutlán como nodo logístico robusto y resiliente, con capacidad de adaptación frente a la evolución del comercio internacional.

3.6.3 Escenario Alto – Cuyutlán como nuevo polo dominante y reconfiguración geográfica del sistema portuario

El escenario alto representa la trayectoria de mayor transformación estructural para el sistema Manzanillo–Cuyutlán. En este caso, la ampliación hacia la Laguna de Cuyutlán no se concibe únicamente como mecanismo de redistribución o expansión funcional, sino como el núcleo de una nueva centralidad portuaria. Bajo esta lógica, el sistema evoluciona desde un modelo históricamente concentrado en el recinto tradicional hacia una configuración jerárquica donde Cuyutlán se convierte en el polo dominante del conjunto.

Esta transformación no es simplemente una cuestión de volumen adicional. Implica un cambio profundo en la geografía operativa, en la asignación de servicios marítimos y en la estructura logística territorial. La nueva terminal no solo absorbe crecimiento incremental, sino que atrae progresivamente servicios ancla, particularmente aquellos asociados a buques de mayor tamaño, escalas de alta intensidad y cadenas logísticas que demandan mayor confiabilidad y menor variabilidad.

En este escenario, la ventaja competitiva de Cuyutlán se fundamenta en condiciones estructurales superiores desde su diseño inicial. La infraestructura marítima se planifica para operar con buques de gran eslora y mayor calado, con dársenas amplias y configuraciones que minimizan interferencias entre posiciones de atraque. La productividad de muelle se mantiene

elevada no solo por equipamiento moderno, sino por la disponibilidad de espacio y la reducción de restricciones heredadas del entorno urbano del recinto histórico.

El diseño de patios en este escenario responde a una lógica de absorción de picos, no de promedio anual. La ocupación promedio se mantiene en niveles que permiten flexibilidad operativa incluso durante eventos de alta concentración de descarga. La rotación de inventario se optimiza mediante integración directa con sistemas intermodales y plataformas logísticas externas de gran escala, que operan como extensiones funcionales del puerto. El patio interno deja de funcionar como almacenamiento regulatorio y se consolida como espacio de tránsito intensivo.

La intermodalidad ferroviaria adquiere en este modelo un carácter dominante. Desde la fase de diseño, la infraestructura contempla formación de trenes completos y programación coordinada con arribos marítimos. La evacuación en bloque reduce la dependencia de la red carretera y disminuye la exposición a congestión urbana. El ferrocarril no es un complemento, sino la columna vertebral del sistema ampliado. La carretera continúa desempeñando un papel relevante para flujos regionales y de corta distancia, pero la estructura global de evacuación se apoya en corredores dedicados de alta capacidad.

En este escenario, la redistribución de servicios es estructural. Parte del volumen previamente atendido en las terminales históricas se migra progresivamente hacia el nuevo polo dominante. Las instalaciones originales no desaparecen, pero evolucionan hacia roles complementarios o especializados. Esta reconfiguración reduce la concentración de riesgo en el recinto tradicional y establece una jerarquía funcional clara dentro del sistema ampliado.

Desde el punto de vista de capacidad máxima efectiva, el escenario alto es el que mayor incremento permite. La combinación de infraestructura de nueva generación, intermodalidad estructural, plataformas externas integradas y gobernanza sistémica reduce significativamente la variabilidad operativa. Al disminuir la variabilidad, el sistema puede operar con mayores niveles de utilización sin caer en congestión estructural. La elasticidad de crecimiento aumenta, permitiendo sostener tasas superiores al cuatro o cinco por ciento anual durante periodos prolongados.

Las proyecciones asociadas a este escenario sitúan el volumen hacia 2050 en rangos superiores a los diez millones de TEU’s anuales. Esta cifra no deriva únicamente de un supuesto de crecimiento económico más acelerado, sino de la capacidad del sistema para absorber volumen adicional sin reproducir cuellos de botella internos. La arquitectura operativa ampliada habilita un nuevo umbral de desempeño.

No obstante, el escenario alto implica mayores exigencias técnicas, financieras e institucionales. La inversión requerida es sustancial y debe planificarse de manera escalonada para evitar sobrecapacidad temporal en fases iniciales. La coordinación entre autoridad portuaria, operadores, sistema ferroviario y autoridades regulatorias debe ser robusta y permanente. Además, al desarrollarse en un entorno lagunar sensible, el proyecto requiere una gestión

ambiental y social rigurosa, con monitoreo continuo y medidas de mitigación integradas desde el diseño.

En términos estratégicos, el escenario alto posiciona al sistema Manzanillo–Cuyutlán como nodo logístico de referencia en el Pacífico ampliado. La centralidad dominante permitiría captar mayor participación en rutas transpacíficas y consolidar el papel del puerto como plataforma de distribución regional. La ventaja competitiva no dependería únicamente del volumen actual, sino de la capacidad de adaptación y expansión futura.

En síntesis, el escenario alto describe una transformación profunda y estructural. No se trata simplemente de ampliar el puerto, sino de redefinir su centralidad y su arquitectura territorial. La evolución hacia un polo dominante implica una reconfiguración geográfica del sistema portuario mexicano en el Pacífico. Es el escenario de mayor ambición y mayor impacto estratégico, pero también el que exige mayor disciplina técnica y visión de largo plazo.

3.7 Comparación Estructural Integrada de los Escenarios hacia 2050

La comparación de los tres escenarios no debe interpretarse únicamente como una variación en volúmenes proyectados al año 2050. La diferencia fundamental entre ellos radica en el régimen operativo adoptado y, en consecuencia, en la arquitectura funcional del sistema Manzanillo–Cuyutlán. Cada escenario representa un nivel distinto de transformación estructural, con implicaciones directas sobre capacidad máxima efectiva, resiliencia operativa, elasticidad de crecimiento y posicionamiento competitivo regional.

El escenario conservador mantiene esencialmente intacta la lógica operativa del recinto histórico. La expansión hacia Cuyutlán incrementa capacidad física, pero no altera de manera profunda la relación entre muelle, patio y el hinterland. El sistema continúa altamente acoplado; la eficiencia depende en gran medida de la evacuación terrestre inmediata y la reducción de congestión es resultado principalmente de mayor espacio disponible. Este modelo permite sostener crecimiento, pero lo hace dentro de una trayectoria que eventualmente converge hacia nuevos límites físicos. La arquitectura no cambia, solo se amplía. La variabilidad operativa disminuye marginalmente, pero la sensibilidad estructural a picos, concentración y disrupciones persiste. En términos estratégicos, el puerto consolida su liderazgo nacional, aunque con margen limitado para expandir significativamente su posición regional.

El escenario central introduce un cambio de régimen funcional. La expansión deja de ser únicamente física y se convierte en instrumento de reorganización logística. La redistribución de servicios entre terminales, la incorporación de plataformas externas integradas y el fortalecimiento estructural de la intermodalidad generan un desacople parcial entre las funciones críticas del sistema. Este desacople es técnicamente relevante, porque reduce la dependencia del patio como regulador forzado y eleva la capacidad máxima efectiva más allá del simple aumento nominal. La elasticidad de crecimiento mejora, ya que el sistema puede absorber mayores

volúmenes sin degradación significativa del rendimiento. Desde la perspectiva estratégica, el puerto no solo crece en escala, sino en estabilidad. El riesgo sistémico se distribuye, la resiliencia aumenta y la competitividad se basa en confiabilidad logística integral. Este escenario representa una transformación profunda pero gradual, con un equilibrio entre ambición y factibilidad.

El escenario alto, en cambio, implica una redefinición geográfica del sistema. La centralidad operativa se desplaza hacia Cuyutlán, que asume el rol dominante dentro del conjunto. Este modelo no solo reorganiza flujos; reestructura la jerarquía interna del sistema portuario. La infraestructura se diseña desde origen para absorber picos intensivos, la intermodalidad ferroviaria opera como eje estructural y las plataformas externas funcionan como extensiones territoriales del puerto. La capacidad efectiva se aproxima a la nominal en mayor proporción, debido a la reducción sustantiva de variabilidad y a la existencia de buffers logísticos amplios. La elasticidad de crecimiento es superior, permitiendo sostener trayectorias que superan ampliamente los diez millones de TEU hacia 2050. Estratégicamente, este escenario posiciona al sistema como nodo de referencia en el Pacífico ampliado. Sin embargo, también implica mayores exigencias financieras, institucionales y ambientales. La complejidad de ejecución es considerable y la disciplina técnica debe ser constante para evitar sobrecapacidad o desalineación entre oferta e integración logística.

La diferencia entre los tres escenarios puede entenderse como una progresión en profundidad de transformación. En el primero, el sistema amplía su escala manteniendo su estructura original. En el segundo, el sistema modifica su arquitectura funcional sin alterar completamente su geografía central. En el tercero, el sistema redefine su centralidad territorial y operativa. Cada paso adicional en esta progresión eleva la capacidad máxima efectiva, reduce la sensibilidad a variabilidad y amplía la elasticidad de crecimiento, pero también incrementa la complejidad de implementación.

Desde la perspectiva de sostenibilidad a largo plazo, el escenario conservador ofrece estabilidad en el corto y mediano plazo, aunque con riesgo de converger nuevamente hacia saturación estructural antes de 2050. El escenario central proporciona una trayectoria de crecimiento sostenible con resiliencia mejorada y menor probabilidad de congestión sistémica. El escenario alto ofrece el mayor potencial de posicionamiento estratégico y escalabilidad, pero requiere condiciones institucionales y financieras sólidas para materializarse plenamente.

En síntesis, la comparación estructural revela que el debate no es entre crecer o no crecer, sino entre mantener un modelo incremental o adoptar una transformación sistémica. La ampliación hacia Cuyutlán es el punto de inflexión que permite optar por cualquiera de las trayectorias. La decisión estratégica determinará si el sistema Manzanillo–Cuyutlán evoluciona como una expansión ampliada del modelo histórico o como una plataforma logística integrada con capacidad de redefinir su papel en el comercio transpacífico hacia 2050.

3.8 Análisis de la Ampliación en la Laguna de Cuyutlán Bajo con base en los Tres escenarios.

3.8.1 Punto de partida: estructura actual (escenario base sin Cuyutlán)

El análisis de la redistribución futura de los flujos contenerizados del Puerto de Manzanillo requiere partir de una caracterización clara y realista de la estructura actual del sistema, entendida no solo como la suma de terminales existentes, sino como un conjunto de relaciones operativas, espaciales y logísticas que determinan la capacidad máxima efectiva del puerto en su configuración vigente.

En ausencia de la ampliación hacia la Laguna de Cuyutlán, el sistema contenerizado de Manzanillo opera bajo un modelo altamente concentrado y espacialmente comprimido, que ha demostrado ser eficiente en términos de crecimiento histórico, pero que hoy exhibe señales claras de saturación funcional y pérdida de holgura.

a. Concentración del manejo de TEU y distribución desigual del riesgo

La estructura actual se caracteriza por una concentración significativa del volumen de TEU en dos terminales principales: SSA Marine México y CONTECON Manzanillo. En conjunto, estas terminales procesan de manera recurrente entre el 70% y el 80% del total de contenedores del puerto, mientras que la Terminal Especializada de Contenedores I (TEC I) y otras instalaciones desempeñan un papel complementario.

Esta concentración no es en sí misma un problema, pero tiene implicaciones críticas para la gestión del riesgo operativo. Al depender de un número reducido de nodos principales, el sistema se vuelve más sensible a perturbaciones locales: cualquier restricción en una de las terminales líderes —ya sea por congestión de patios, saturación de accesos o eventos operativos— tiene efectos inmediatos y amplificados sobre el conjunto del puerto.

En el escenario base, el crecimiento futuro de la demanda se canaliza necesariamente hacia estas mismas terminales, reforzando el ciclo de concentración y reduciendo progresivamente los márgenes de maniobra del sistema.

b. Limitaciones espaciales del recinto portuario actual

Desde el punto de vista físico, el recinto portuario actual de Manzanillo presenta limitaciones estructurales de espacio. La expansión de patios, áreas de respaldo y zonas de regulación se enfrenta a restricciones geográficas, urbanas y ambientales que dificultan incrementos significativos de superficie sin afectar otros usos o generar conflictos adicionales.

Esta compresión espacial obliga a maximizar la utilización del espacio disponible, lo que se traduce en altos niveles de ocupación promedio en patios y áreas operativas. Si bien esta estrategia permite sostener volúmenes elevados en el corto plazo, reduce la capacidad del sistema para absorber picos operativos y aumenta la probabilidad de congestión interna.

c. Desfase entre productividad de muelle y capacidad de evacuación

Las terminales líderes han invertido de manera consistente en incrementar la productividad en muelle, incorporando grúas pórtico de alta capacidad y equipamiento moderno. Como resultado, la capacidad teórica de transferencia muelle–buque ha aumentado de forma significativa en los últimos años.

No obstante, este aumento no siempre ha sido acompañado por un crecimiento equivalente en la capacidad de evacuación terrestre y en los espacios de regulación logística. En el escenario base, el sistema presenta un desfase estructural: los contenedores pueden descargarse más rápido de los buques, pero no siempre pueden evacuarse con la misma rapidez hacia el hinterland.

Este desfase genera acumulación temporal en patios, incrementa los movimientos internos improductivos y reduce la eficiencia global, especialmente durante periodos de alta demanda.

d. Dependencia crítica del hinterland inmediato

El sistema actual depende de manera significativa de la capacidad del hinterland inmediato para absorber los flujos contenerizados. La mayor parte de la carga se evacúa por carretera y ferrocarril hacia el centro y occidente del país, utilizando corredores que, en muchos casos, operan cerca de su capacidad en horas pico.

En el escenario base, la falta de plataformas logísticas externas plenamente integradas implica que funciones como almacenamiento temporal, consolidación, desconsolidación e inspección se realicen en gran medida dentro o en las inmediaciones del recinto portuario. Esta concentración funcional incrementa la presión sobre los accesos y limita la flexibilidad del sistema.

e. Interferencia operativa en un puerto multipropósito

Manzanillo opera como un puerto multipropósito, donde los flujos de contenedores coexisten con graneles minerales, graneles agrícolas, carga general y energéticos. En el escenario base, esta coexistencia se da en un espacio limitado, lo que exige una gestión fina de la zonificación y de los tiempos de operación.

La interferencia entre tráficos no siempre se manifiesta en conflictos directos, pero sí en restricciones operativas acumulativas, como ventanas horarias, áreas de seguridad y segregación de flujos, que reducen la flexibilidad del sistema y afectan la capacidad máxima efectiva.

f. Reducción progresiva de la resiliencia operativa

La suma de concentración, limitaciones espaciales, desfases logísticos e interferencias multipropósito conduce a una reducción progresiva de la resiliencia operativa del puerto en su configuración actual. En el escenario base, el sistema tiene una capacidad limitada para absorber perturbaciones externas sin degradar su nivel de servicio.

Eventos como retrasos de buques, cambios en itinerarios navieros, disrupciones en los corredores terrestres o incrementos súbitos de demanda pueden generar efectos en cascada que afectan no solo a una terminal, sino al puerto en su conjunto.

g. Implicaciones del escenario base para el crecimiento futuro

En ausencia de la ampliación hacia Cuyutlán, el escenario base impone un techo operativo claro al crecimiento sostenible del Puerto de Manzanillo. Si bien el puerto puede seguir creciendo en términos de volumen anual, lo hará con costos crecientes, mayor volatilidad operativa y un riesgo elevado de congestión recurrente.

Desde una perspectiva de planeación estratégica, este escenario base constituye el punto de referencia indispensable para evaluar los beneficios de la expansión y de la transición hacia un modelo port-led. Solo al entender plenamente las limitaciones del sistema actual es posible dimensionar el impacto real de la nueva terminal y de la redistribución futura de los flujos contenerizados.

En resumen, antes de la entrada de Cuyutlán, la participación promedio de TEU’s se concentra de la siguiente manera:

- SSA Marine México: aproximadamente del 40% al 45%
- CONTECON Manzanillo: aproximadamente del 30% al 35%
- TEC I: aproximadamente del 15% al 20%
- Instalaciones multipropósito: <5 %

Este esquema refleja un sistema altamente concentrado, donde dos terminales absorben la mayor parte del crecimiento y, con ello, la mayor parte de los picos operativos y del riesgo sistémico.

3.8.2 Escenario 1: Cuyutlán como expansión "adicional" (redistribución limitada).

En este escenario, la ampliación hacia la Laguna de Cuyutlán se incorpora al sistema portuario de Manzanillo principalmente como capacidad incremental —es decir, como un "nuevo espacio" que suma oferta— sin provocar una redistribución profunda y deliberada de los flujos que hoy se concentran en las terminales existentes del recinto actual. En términos de planeación, este es el escenario que ocurre cuando la expansión se concibe como respuesta a la saturación, pero el diseño institucional, logístico y de mercado no llega a reconfigurar el sistema completo bajo una lógica port-led.

El propio PMDP reconoce que el Puerto de Manzanillo opera hoy como el principal nodo contenerizado del país, y que el crecimiento reciente ha llevado al puerto a un punto donde la expansión hacia Cuyutlán aparece como parte de una trayectoria natural de desarrollo. En esa visión, la Laguna de Cuyutlán aparece como un espacio que, en el mediano y largo plazo, puede atender tráficos que el puerto actual no puede absorber por limitaciones de dimensiones, calados y áreas de navegación.

Esta idea —Cuyutlán como "válvula de crecimiento" y opción para buques mayores— es el fundamento conceptual del Escenario 1: sumar capacidad sin alterar de inmediato la estructura dominante del reparto de TEU's.

a. Supuesto central: el crecimiento se "va" a Cuyutlán, pero lo existente no se mueve

El rasgo definitorio del escenario es que SSA y CONTECON mantienen la base histórica de servicios y contratos, y la nueva terminal de Cuyutlán captura, sobre todo:

- crecimiento neto de demanda (TEU's adicionales del sistema),
- servicios nuevos que entran por razones comerciales (cambios de red naviera),
- y, de forma limitada, algunos desahogos operativos (picos puntuales o campañas estacionales).

Es decir, Cuyutlán entra como capacidad adicional, pero la redistribución de TEU's entre terminales es limitada porque no hay (todavía) una estrategia sistémica de "relocalización" de funciones ni una política portuaria explícita de migración de servicios desde el puerto actual.

En la práctica, esto suele ocurrir por tres razones técnicas:

1. Inercia comercial y contractual: las navieras tienden a conservar escalas donde ya existe confiabilidad operativa, redes de agentes, conectividad terrestre y acuerdos vigentes con terminales.

2. Ramp-up inevitable: la nueva terminal necesita un periodo de maduración: afinación operativa, estabilización de productividad, confiabilidad del gate, interoperabilidad aduanal y consolidación de patrones de evacuación.

3. Hinterland aún no reconfigurado: sin patios externos plenamente integrados, accesos dedicados y una gobernanza logística "ampliada", Cuyutlán opera como puerto "nuevo" pero dentro del mismo cuello de botella macro: la evacuación terrestre y la regulación logística siguen dependiendo del sistema existente.

b. Qué cambia realmente, aunque la redistribución sea limitada: el techo operativo se desplaza, pero no se rompe.

Aun con redistribución limitada, la entrada de Cuyutlán sí mejora el sistema, pero lo hace de una manera específica: aumenta la capacidad física y abre una opción de operación para buques o tráficos que presionan al recinto actual, lo que el PMDP plantea explícitamente como parte del desarrollo de mediano y largo plazo.

Sin embargo, desde la perspectiva de la capacidad máxima efectiva, el beneficio es parcial porque los cuellos de botella sistémicos no desaparecen: cambian de intensidad, pero no se reubican completamente.

- **Muelle**: se incorpora frente de atraque adicional (o futura infraestructura) en el polígono de Cuyutlán, lo cual reduce la probabilidad de que el sistema "tope" por disponibilidad de posiciones. El PMDP detalla que el sistema portuario incluye múltiples posiciones de atraque y distingue infraestructura en Manzanillo y en la Laguna de Cuyutlán, además de describir áreas de navegación y protección asociadas.
- **Patio**: en un escenario 1, el patio nuevo funciona como "pulmón adicional", pero si no se acompaña de cambios fuertes en logística externa, ese pulmón empieza a llenarse cuando el sistema crece y se acerca otra vez a la saturación.
- **Accesos y evacuación terrestre**: el PMDP muestra que la conectividad carretera y ferroviaria es un componente estructural del puerto y describe la operación ferroviaria y vialidades que sirven al recinto.

En este escenario, esa conectividad no se transforma al mismo ritmo que el crecimiento, por lo que la capacidad efectiva sigue "amarrada" a la evacuación.

En síntesis: se mueve el techo hacia arriba, pero no se rompe el patrón de saturación recurrente; el sistema gana tiempo y margen, pero no cambia su lógica profunda de funcionamiento.

c. Cómo se comportan los picos operativos en este escenario: se reducen episodios críticos, pero no se elimina la volatilidad

Un aporte técnico importante de Cuyutlán, incluso en redistribución limitada, es que permite "absorber picos" en el componente marítimo (atraques y programación) y, en cierta medida, redistribuir ventanas operativas.

No obstante, la naturaleza del problema en Manzanillo es que los picos no solo ocurren en muelle; se trasladan al patio, al gate y al hinterland. En un escenario 1, los picos se desplazan y se reparten, pero el sistema sigue vulnerable porque:

- la logística terrestre continúa concentrada en corredores y nodos existentes,
- las decisiones de despacho siguen afectadas por inspecciones, regulación y tiempos de retiro,
- y, las terminales dominantes siguen absorbiendo la mayor parte del volumen estructural, con la misma dependencia de accesos.

El resultado es que el puerto puede reducir episodios extremos de congestión, pero la volatilidad operativa permanece, solo que con un umbral ligeramente más alto antes de que se manifieste.

d. Implicaciones para la participación de TEU's por terminal: el cambio es visible, pero moderado

En este escenario, la nueva terminal de Cuyutlán participa desde el arranque como un actor adicional, pero sin "desplazar" de manera significativa a los líderes históricos. El reparto de TEU's evoluciona hacia una configuración de transición donde:

- SSA y CONTECON mantienen la mayor proporción del total,
- TEC I sostiene su rol complementario,
- Y, Cuyutlán absorbe principalmente crecimiento incremental y algunos servicios nuevos.

En términos de lógica portuaria, esto es coherente con una expansión que se incorpora como capacidad de respaldo y válvula de expansión, más que como un nuevo centro dominante. Es también consistente con la visión del PMDP de que Cuyutlán se vuelve una opción relevante para el desarrollo futuro del sistema portuario, sin implicar necesariamente una migración inmediata de la operación existente.

e. Riesgos técnicos y limitaciones típicas del Escenario 1

Este escenario es "realista" porque coincide con cómo suelen comportarse muchas expansiones portuarias en su primera etapa. Sin embargo, desde una perspectiva técnica, tiene límites claros:

1. Riesgo de "capacidad física sin capacidad efectiva": Si el aumento de capacidad en muelle y patio no se acompaña de mejoras equivalentes en evacuación (ferrocarril, carretera, patios externos, gestión de citas y control de inventarios), la capacidad efectiva crece menos que la capacidad nominal.

2. Persistencia del riesgo sistémico por concentración: Al mantenerse la dominancia de dos terminales, el sistema sigue expuesto: cualquier disrupción en esos nodos se amplifica.

3. Ganancias con rendimientos decrecientes: El escenario 1 suele ser muy útil para "comprar tiempo" y aliviar saturaciones, pero conforme el volumen total vuelve a crecer, el sistema se aproxima otra vez a un punto de tensión, solo que a un nivel mayor.

f. Qué habilita (y qué no habilita) este escenario para 2026–2050.

Para fines de proyección 2026–2050, el Escenario 1 permite justificar un crecimiento relevante de TEU en el corto y mediano plazo porque agrega capacidad y reduce ciertos cuellos en el componente marítimo. Pero difícilmente sostiene por sí solo los escenarios altos de largo plazo, porque no transforma de manera suficiente la estructura que define la capacidad máxima efectiva: patios-regulación-evacuación.

Por eso, técnicamente, el Escenario 1 debe entenderse como una etapa transitoria: necesaria, pero insuficiente si la meta es consolidar a Manzanillo–Cuyutlán como un sistema port-led plenamente maduro.

En resumen, este escenario, la nueva terminal de Cuyutlán entra en operación principalmente como capacidad incremental, orientada a captar crecimiento futuro más que a redistribuir volúmenes existentes. El modelo operativo del puerto se mantiene esencialmente igual, con mejoras puntuales, pero sin una transformación profunda del esquema logístico.

a. Lógica operativa

- SSA y CONTECON conservan la mayor parte de sus flujos históricos.
- La nueva terminal absorbe principalmente crecimiento marginal y algunos servicios nuevos.

- La presión sobre el sistema existente se reduce solo parcialmente.

b. Redistribución aproximada de participación (en régimen inicial)

- SSA Marine México: aproximadamente entre el 35% al 38%
- CONTECON Manzanillo: aproximadamente entre el 28% al 32%
- TEC I: aproximadamente entre el 12% al 15%
- Nueva terminal Cuyutlán: aproximadamente entre el 15% al 20%
- Otros: <5 %

c. Implicación clave

La concentración se reduce, pero no desaparece. El sistema gana capacidad física, pero la capacidad máxima efectiva mejora de forma limitada. Las tensiones operativas tienden a reaparecer conforme el volumen total crece.

En resumen, el escenario conservador corresponde a un modelo de expansión adicional de carácter incremental. En este caso, la ampliación hacia la Laguna de Cuyutlán incrementa la capacidad física disponible mediante nuevos muelles y patios, pero no modifica de manera sustancial la arquitectura funcional del sistema. El puerto ampliado continúa operando bajo una lógica en la cual el recinto concentra la mayor parte de las funciones críticas: transferencia marítima, regulación de inventario y despacho terrestre. La redistribución de servicios entre terminales es limitada y la intermodalidad ferroviaria mantiene un papel complementario frente al transporte carretero. Desde el punto de vista conceptual, este escenario equivale a la evolución de un puerto tipo enclave o landlord ampliado, donde la infraestructura crece, pero la lógica sistémica permanece esencialmente intacta. El sistema aumenta su escala, pero no cambia su régimen operativo. Esto permite sostener crecimiento, aunque dentro de límites estructurales que tienden a reaparecer conforme el volumen se aproxima nuevamente a niveles elevados de utilización.

Este escenario es típico de expansiones portuarias que añaden muelle, pero no reconfiguran el sistema.

3.8.3 Escenario 2: Cuyutlán como redistribuidor funcional (escenario port-led “central”)

El Escenario 2 (port-led “central”) es, desde la ingeniería operativa y la planeación logística, el escenario en el que Cuyutlán no solo añade muelle, sino que actúa como un redistribuidor funcional del sistema contenerizado Manzanillo–Cuyutlán. La diferencia clave respecto al Escenario 1 es que aquí la nueva terminal sí cambia el equilibrio del sistema, porque se acompaña de decisiones deliberadas sobre asignación de servicios, arquitectura logística externa, intermodalidad y gobernanza operativa. Eso permite elevar de manera sostenida la capacidad máxima efectiva (no solo la nominal) y reducir la vulnerabilidad a picos.

a. Qué significa "redistribuidor funcional" en términos operativos (y por qué es port-led)

Un redistribuidor funcional no es una terminal nueva "más"; es un nodo que reorganiza flujos y funciones para que el sistema completo opere con holgura. En Manzanillo, el cuello de botella no es únicamente marítimo (atraques), sino el acoplamiento muelle–patio–acceso–corredores. Por eso, Cuyutlán solo se vuelve "central" si se diseña como parte de una arquitectura port-led, donde el puerto deja de ser el límite geográfico del sistema y pasa a ser el ancla de una red logística ampliada.

En este escenario, el puerto actual (SSA, CONTECON, TEC I) deja de absorber por sí solo los incrementos marginales de demanda. La nueva terminal en Cuyutlán se convierte en el mecanismo que toma parte del crecimiento y parte del volumen existente, y además "expulsa" hacia afuera (fuera del recinto) varias funciones que hoy compiten por espacio y tiempo dentro del puerto.

En términos prácticos, port-led aquí significa que los contenedores no se gestionan como inventario dentro del puerto, sino como flujo. El sistema se rediseña para que el puerto sea el punto de transferencia y control, mientras que el almacenamiento regulatorio, el manejo de vacíos, parte de la inspección y ciertas actividades de valor agregado se ubiquen en plataformas externas conectadas (por carretera y ferrocarril) que operan coordinadas con las terminales.

b. Supuesto estructural del escenario: la redistribución es una decisión del sistema, no un efecto espontáneo del mercado

En el Escenario 1, la terminal nueva "se gana" su volumen casi únicamente con crecimiento futuro y con oportunidades comerciales aisladas. En el Escenario 2, en cambio, hay una estrategia explícita para que Cuyutlán reciba un portafolio funcional de tráficos, típicamente compuesto por tres componentes:

- **Servicios de mayor tamaño y mayor intensidad de pico**. La lógica es sencilla: si el sistema actual sufre cuando la demanda se concentra, lo más racional es que el nuevo nodo absorba una parte de esas escalas, con patio y gate diseñados para picos, y con conexión directa a plataformas externas.
- **Crecimiento incremental de la región (2029–2035)**. La nueva terminal es el "punto de aterrizaje" natural del crecimiento, pero con un diseño institucional que evita que ese crecimiento vuelva a saturar las terminales existentes.
- **Una migración gradual de volúmenes "compatibles" desde las terminales líderes**. No se trata de "quitarle" carga a SSA o CONTECON por decreto, sino de crear condiciones para que parte de sus flujos migren por eficiencia del sistema:

menores tiempos de gate, mejor previsibilidad, accesos más fluidos, intermodalidad más consistente o capacidad superior para ciertos tamaños de buque.

Esta redistribución no puede ocurrir si Cuyutlán opera aislado. Requiere un sistema de coordinación (operacional y comercial) que haga que navieras, autotransporte y ferrocarril perciban al sistema Manzanillo–Cuyutlán como un solo puerto ampliado, no como dos puertos compitiendo por el mismo hinterland.

c. El "mecanismo técnico" que permite redistribuir: desacoplar muelle de hinterland

El núcleo técnico del Escenario 2 es el desacoplamiento. Hoy, el sistema tiende a "pegarse" cuando los contenedores descargados no pueden evacuar. En un esquema port-led, el objetivo es que el muelle no dependa de la evacuación inmediata hacia destino final, sino de la evacuación hacia capacidad regulatoria externa.

Eso se logra con tres piezas que operan como un solo circuito:

1. Patios y plataformas externas como regulador (buffer) del sistema: Se construyen o consolidan patios externos, preferentemente con acceso ferroviario y con procesos aduanales compatibles (según el esquema que aplique), para que una parte del inventario no permanezca dentro del puerto. La consecuencia directa es que el patio portuario vuelve a ser un espacio de transferencia eficiente, no un almacén "forzado".

2. Intermodalidad (ferrocarril) y coordinación de ventanas: En el escenario central, la participación ferroviaria tiende a aumentar porque el ferrocarril es, operativamente, el instrumento más potente para "sacar volumen" cuando hay picos. Pero lo decisivo no es solo tener vía: es que exista una planificación de trenes por ventana, alineada con arribos de buques, y que la terminal pueda armar y despachar trenes sin congestionar el gate.

3. Gestión del gate basada en citas y control de llegada: No basta con ampliar carriles; la palanca real para evitar colas y saturación es un sistema de gate donde el camión llega cuando el contenedor está "listo", con un patrón de entradas y salidas que no colapsa en horas punta. En el Escenario 2, la mejora de gate es condición para que Cuyutlán efectivamente redistribuya, porque si el gate nuevo sufre el mismo problema, el sistema simplemente traslada la congestión.

Cuando estas tres piezas funcionan, el puerto gana algo esencial: la capacidad de absorber picos sin que el patio colapse. Y eso eleva la capacidad máxima efectiva.

d. Redistribución esperada de participación de TEU en el escenario central (en régimen maduro).

En un escenario central realista, Cuyutlán no se vuelve dominante absoluto, pero sí se convierte en el tercer pilar del sistema. Lo normal es que el sistema pase de "duopolio" (SSA + CONTECON) a "tripolar" (SSA + CONTECON + Cuyutlán), con TEC I estabilizado en un rol complementario.

Por eso, en régimen maduro, el rango típico que se observa en ejercicios de planeación comparables es:

- SSA se ajusta a un peso menor que el actual, no por pérdida de relevancia, sino porque el sistema deja de depender de ella para absorber crecimiento y picos.
- CONTECON también reduce ligeramente su participación relativa (aunque puede mantener o incluso aumentar volumen absoluto si el total crece).
- Cuyutlán toma una fracción sustantiva, no solo de crecimiento incremental, sino de flujos que hoy elevan la presión del sistema.
- TEC I tiende a "adelgazarse" en participación relativa conforme el total crece, manteniendo funciones estabilizadoras, nichos o complementariedad.

El valor técnico de esta redistribución no es "cambiar porcentajes", sino reducir concentración del riesgo: que ningún nodo por sí solo sea el determinante del desempeño de todo el puerto.

e. Cómo cambia el comportamiento de los picos (la razón por la que este escenario habilita 2035–2050)

El beneficio distintivo del Escenario 2 es que los picos dejan de "convertirse" automáticamente en congestión sistémica. Técnicamente, ocurre una transición:

En el escenario base o en el Escenario 1, un pico de llegada se traduce en saturación de patio y gate, porque la evacuación depende del mismo recinto y de los mismos accesos.

En el Escenario 2, el pico se procesa en dos etapas: primero se transfiere del buque a patio y de patio a buffer/intermodal con reglas de prioridad; después se evacua hacia destino final con una curva más suave. El sistema vuelve a tener amortiguación. Eso se traduce en tres mejoras que son medibles y defendibles:

- La permanencia promedio del contenedor dentro del recinto tiende a disminuir (mejor rotación).
- La productividad en muelle deja de "caerse" en semanas de alta ocupación, porque el patio no colapsa.

- Los tiempos de gate se estabilizan, reduciendo la variabilidad, que es el peor enemigo de la planificación logística.

Por eso, este escenario es el que realmente sostiene proyecciones de largo plazo: porque convierte el crecimiento en algo operable, no en un número.

f. Condiciones mínimas para que el Escenario 2 sea viable (criterios técnicos, no aspiracionales).

Este escenario solo es alcanzable si se cumplen condiciones técnicas concretas. Las más críticas son:

- Capacidad regulatoria fuera del puerto (patios externos y plataformas) operando como parte del sistema, no como soluciones aisladas.
- Conectividad dedicada y confiable entre Cuyutlán y su hinterland inmediato (para que no se "meta" a la misma trampa de accesos del puerto actual).
- Interoperabilidad de procesos (aduanales, inspección, liberaciones y trazabilidad) para que mover carga entre nodos no agregue fricción administrativa.
- Gobernanza operativa de sistema: un mecanismo de coordinación para asignación de ventanas, gestión de picos, contingencias y reglas de priorización (por ejemplo, en episodios de congestión o disrupciones).

Sin estas condiciones, Cuyutlán tiende a caer al Escenario 1: suma capacidad, pero no transforma el sistema.

g. Implicación directa para proyecciones 2026–2050.

El Escenario 2 es el punto medio "realista-ambicioso". Habilita crecimiento alto sin requerir que Cuyutlán se vuelva el polo dominante absoluto, pero sí exige una transformación de sistema. En ese sentido, es el escenario que mejor "amarra" con la lógica de largo plazo: permite que Manzanillo–Cuyutlán deje de estar definido por el techo operativo del recinto actual y pase a ser un sistema ampliado con holgura y resiliencia.

En resumen, este escenario, la nueva terminal se integra explícitamente en un modelo port-led, con patios externos, accesos dedicados y una estrategia deliberada de redistribución de flujos. Parte del volumen que hoy se concentra en SSA y CONTECON se desplaza gradualmente hacia Cuyutlán.

a. Lógica operativa

- Cuyutlán absorbe nuevos servicios de gran escala y parte de los flujos más intensivos en picos.

- Las terminales existentes se estabilizan en niveles de utilización más manejables.
- El sistema gana holgura operativa y resiliencia.

b. Redistribución aproximada de participación (en régimen maduro)

- SSA Marine México: aproximadamente entre el 30% al 33%
- CONTECON Manzanillo: aproximadamente entre el 25% al 28%
- TEC I: aproximadamente entre el 10% al 12%
- Nueva terminal Cuyutlán: aproximadamente entre el 25% al 30%
- Otros: <5 %

c. Implicación clave

El puerto pasa de un esquema “dos terminales dominantes” a un sistema tripolar, donde ninguna terminal concentra por sí sola el riesgo sistémico. La capacidad máxima efectiva del puerto aumenta de manera estructural.

En resumen, el escenario central representa un cambio de régimen funcional. Aquí la ampliación hacia Cuyutlán no se limita a agregar capacidad, sino que se utiliza como instrumento para reorganizar el sistema completo bajo un enfoque port-led maduro. La redistribución de servicios es real y deliberada; parte de los flujos de mayor intensidad operativa se trasladan al nuevo polo, reduciendo la concentración histórica en pocas terminales. Al mismo tiempo, se incorporan plataformas logísticas externas que funcionan como extensión del puerto y permiten desacoplar parcialmente el muelle del hinterland. La intermodalidad ferroviaria adquiere un peso estructural, lo que reduce la dependencia exclusiva de la red carretera y disminuye la variabilidad operativa. Conceptualmente, este escenario corresponde a la transición hacia un modelo port-led integrado, donde el puerto deja de ser únicamente un recinto ampliado y se convierte en el eje de un sistema logístico territorial más amplio. El crecimiento no depende solo de superficie adicional, sino de reducción de variabilidad y mejora de la capacidad máxima efectiva. Se trata de una transformación profunda pero equilibrada, que eleva la resiliencia del sistema sin modificar radicalmente su geografía central.

Este es el escenario más coherente con las proyecciones 2035–2050 y con la lógica de planeación de largo plazo.

3.8.4 Escenario 3: Cuyutlán como nuevo polo dominante (escenario alto)

En este escenario, el desarrollo en la Laguna de Cuyutlán no solo se integra como una extensión del Puerto de Manzanillo, sino que se convierte en el nuevo polo dominante del sistema contenerizado. La lógica fundamental es que Cuyutlán alcanza, en relativamente pocos años, un desempeño y una escala que lo posicionan como el principal nodo de contenedores del sistema

ampliado, mientras que las terminales del puerto actual (SSA, CONTECON y TEC I) mantienen operación relevante, pero con un rol más complementario, especializado o de nicho.

A diferencia del Escenario 2, donde Cuyutlán es un redistribuidor central pero no necesariamente dominante, aquí se asume que el nuevo puerto atrae la mayoría del crecimiento incremental y además captura una porción significativa del volumen existente, en particular los servicios de línea principal y los flujos asociados a buques de mayor tamaño, mayores picos operativos o mayores exigencias de confiabilidad.

Este escenario es técnicamente viable, pero solo bajo condiciones exigentes y explícitas: requiere que Cuyutlán se diseñe como una terminal de última generación con ventajas operativas claras y sostenibles frente al puerto actual, y que el sistema logístico-terrestre se configure para soportar volúmenes significativamente mayores sin reproducir los cuellos de botella actuales.

a. Qué hace que un "polo nuevo" sea dominante: ventaja estructural, no solo capacidad.

Para que Cuyutlán sea dominante no basta con construir más muelle. La dominancia portuaria ocurre cuando el nodo nuevo logra una ventaja estructural en cuatro dimensiones que los usuarios valoran de forma determinante (navieras, cargadores, operadores terrestres):

- Productividad y confiabilidad (variabilidad baja, no solo promedios altos).
- Capacidad de absorber picos sin congestión sistémica.
- Menor fricción en accesos y gate (tiempos predecibles).
- Intermodalidad competitiva (ferrocarril y plataformas externas integradas).

En un puerto con tensiones operativas, la ventaja más decisiva es la confiabilidad: si Cuyutlán ofrece menor variabilidad de tiempos de atraque, despacho y retiro, entonces parte del volumen migra incluso sin una "política de migración"; migra porque el mercado busca menor incertidumbre.

b. El mecanismo central del Escenario 3: migración de servicios "ancla" y reconfiguración de redes navieras.

El Escenario 3 depende de que Cuyutlán no solo reciba carga incremental, sino que capture servicios ancla (services loops) que hoy sostienen gran parte del volumen en SSA o CONTECON. En la práctica, esto implicaría que:

- algunos servicios de línea principal (Asia–México / Asia–costa oeste / conexiones regionales) redefinen su escala principal hacia Cuyutlán;

- parte del transbordo (si existe) se concentra en el nuevo polo, aprovechando productividad y programación;
- y, el puerto actual se reacomoda como soporte, absorbiendo tráficos más estables, ciertos nichos, o un mix multipropósito con menor presión de picos.

Esta migración es más probable si el polo nuevo ofrece mayores profundidades, posiciones de atraque y patios diseñados para megaescalas, con operación y accesos robustos desde el primer día. En un escenario alto, el ramp-up es más rápido porque la terminal nace con una configuración “lista para mercado”, no como una expansión gradual.

c. Cambios en la arquitectura logística: Cuyutlán como puerto-gateway + sistema port-led maduro

Un polo dominante no funciona aislado. Si Cuyutlán se vuelve dominante, el sistema debe operar como port-led maduro, donde el puerto actúa como gateway y la logística de regulación se desplaza fuera del muelle.

Esto significa que, en el Escenario 3, las funciones logísticas se reordenan así:

- El recinto portuario se especializa en transferencia y control, minimizando permanencias largas.
- La regulación del inventario y el manejo de vacíos se traslada a patios externos conectados, con trazabilidad en tiempo real.
- La desconsolidación / valor agregado / inspección programada se organiza en plataformas logísticas externas, reduciendo la presión sobre patios internos.
- La intermodalidad (ferro–carretera) deja de ser “complemento” y se convierte en columna vertebral del sistema.

Bajo esta arquitectura, el sistema puede sostener crecimientos más altos por más años sin saturación, porque el puerto deja de ser el punto donde se “acumula” la carga.

d. Redistribución esperada de TEU por terminal: hacia una nueva geometría del sistema

En régimen, la redistribución en un escenario dominante tiende a adoptar una forma clara: Cuyutlán concentra la mayor fracción, y las terminales existentes reducen participación relativa, aunque pueden mantener volumen absoluto si el total crece.

La razón técnica es doble:

- La nueva infraestructura se diseña para atender las escalas más intensivas (picos y megabuques) y por tanto captura gran parte de los “TEU críticos” que determinan la congestión.

- La nueva conectividad y logística externa hacen que el nuevo polo sea más competitivo en tiempos y confiabilidad, atrayendo volumen incluso de servicios ya existentes.

En términos de lectura portuaria, el sistema deja de ser "duopolio" (SSA+CONTECON) o "tripolar equilibrado" (Escenario 2) y pasa a ser un sistema con polo central dominante y nodos complementarios.

e. Cómo cambian los picos y la capacidad máxima efectiva en el Escenario 3

El Escenario 3 no solo redistribuye volumen; reconfigura la dinámica del riesgo operativo.

1. Picos: de problema sistémico a problema gestionable

Hoy los picos generan congestión porque el sistema tiene poca amortiguación y los patios se saturan. En el escenario dominante, Cuyutlán está diseñado para absorber picos por tres vías simultáneas:

- patio dimensionado para alta intensidad de descarga/carga,
- entrada y accesos con capacidad y control de llegadas,
- y, salidas intermodales (sobre todo ferroviarias) que permiten evacuar volumen en bloques.

El efecto neto es que la variabilidad de desempeño se reduce: el sistema se vuelve más predecible. En logística, esta reducción de variabilidad es el componente más valioso para la competitividad.

2. Capacidad máxima efectiva: incremento sostenido

En términos de capacidad máxima efectiva, el escenario dominante es el que más eleva el techo del sistema porque no solo añade infraestructura: cambia el modo de operación. Los rendimientos de la infraestructura son mayores porque la nueva terminal opera con holgura y con menor interferencia urbana, y porque el port-led desplaza funciones fuera del puerto.

f. Condiciones técnicas mínimas para que el Escenario 3 sea plausible

Este escenario es exigente. Para que no sea aspiracional, debe apoyarse en condiciones técnicas concretas:

1. Infraestructura marítima “de línea principal”

    - Profundidad y áreas de maniobrabilidad adecuados para buques grandes.
    - Áreas de maniobra y protección que permitan operación confiable en condiciones variables.
    - Diseño del frente de atraque que permita productividad alta y simultaneidad.

2. Patio y equipos dimensionados para picos, no para promedio

    - Patios con capacidad de regulación y configuración que minimice movimientos improductivos.
    - Equipamiento de patio y muelle alineado a la estrategia operativa (no sobredimensionado “en papel” pero sin capacidad real de sostener productividad).

3. Accesos dedicados y política de gate

    - Capacidad de gate con control de citas y mecanismos de regulación.
    - Separación funcional de flujos (importación/exportación/vacíos) para evitar colapso.

4. Intermodalidad como palanca principal

    - Infraestructura ferroviaria y operación por ventanas coordinadas con arribos de buques.
    - Plataformas externas conectadas que funcionen como “extensión” del puerto.

5. Gobernanza y coordinación del sistema ampliado

    - Un esquema de coordinación puerto–terminales–aduana–autotransporte–ferrocarril que permita gestionar picos y contingencias como sistema único.

Sin estos componentes, el Escenario 3 degenera en una versión “grande” del Escenario 1: mucha obra, poca transformación efectiva.

g. Riesgos y trade-offs del Escenario 3

Como todo escenario alto, tiene riesgos que deben declararse en el informe:

- Riesgo de sobrecapacidad temporal si el ramp-up comercial no acompaña la escala de inversión.

- Riesgo de desplazamiento de congestión: si el cuello de botella pasa al hinterland, el puerto nuevo puede saturarse rápido.
- Riesgo social y ambiental: al ser un entorno lagunar sensible, la viabilidad ambiental y social debe ser un componente central del diseño; de lo contrario, el proyecto puede enfrentar retrasos que alteren el ramp-up.
- Riesgo de coordinación: un polo dominante requiere gobernanza robusta para evitar competencia desordenada entre terminales y para asegurar interoperabilidad operativa.

h. Implicación directa para proyecciones 2026–2050

Este escenario es el que habilita los rangos más altos de TEU hacia 2050 porque permite crecimiento sostenido sin reaparición rápida de saturación. Sin embargo, es coherente plantearlo como “escenario alto” por dos razones:

- requiere mayor inversión y coordinación,
- y, exige una transición real a port-led, no solo ampliación portuaria.

En el marco del informe, el Escenario 3 funciona como el “máximo plausible” bajo desempeño y gobernanza sobresalientes, útil para dimensionar infraestructura y reservar territorio, mientras el Escenario 2 suele ser el “objetivo realista” de planeación.

En este escenario, Cuyutlán se diseña y opera como una terminal de última generación, altamente competitiva, con fuerte conectividad intermodal y capacidad para atraer servicios de línea principal y transbordos regionales.

a. Lógica operativa

- Cuyutlán capta una proporción significativa de servicios de gran tamaño.
- Parte del crecimiento futuro y parte del volumen actual se desplaza hacia el nuevo puerto.
- Las terminales existentes evolucionan hacia roles más especializados o de nicho.

b. Redistribución aproximada de participación (largo plazo)

- SSA Marine México: aproximadamente entre el 25% al 28%
- CONTECON Manzanillo: aproximadamente entre el 20 al 25%
- TEC I: aproximadamente entre el 8 al 10%
- Nueva terminal Cuyutlán: aproximadamente entre el 35% al 40%
- Otros: <5 %

c. Implicación clave

El sistema adquiere una nueva geometría, con Cuyutlán como polo principal y el puerto actual como complemento. Este escenario maximiza la capacidad efectiva total, pero requiere:

- inversiones mayores en accesos y logística externa,
- gobernanza portuaria fuerte,
- y, una coordinación avanzada con navieras y operadores terrestres.

Desde una perspectiva técnica, los tres escenarios muestran que la entrada de Cuyutlán siempre reduce la concentración, pero solo los escenarios 2 y 3 modifican de forma sustantiva la capacidad máxima efectiva y la resiliencia del sistema.

La diferencia clave no es el porcentaje exacto, sino el rol funcional asignado a la nueva terminal:

- Si Cuyutlán solo “suma capacidad”, el sistema sigue operando cerca del límite.
- Si Cuyutlán redistribuye flujos y funciones, el techo operativo se desplaza hacia arriba.
- Si Cuyutlán se convierte en polo dominante, el sistema entra en una nueva fase de desarrollo portuario.

Estos escenarios de redistribución son el puente técnico entre la estructura actual y las proyecciones de largo plazo. Los escenarios de crecimiento más ambiciosos (2035–2050) solo son plausibles bajo esquemas similares a los escenarios 2 o 3, donde la nueva terminal en Cuyutlán no solo absorbe volumen, sino que reorganiza el sistema portuario completo bajo un enfoque port-led.

En resumen, el escenario alto implica una transformación aún más profunda, que no solo reorganiza funciones, sino que redefine la centralidad del sistema. En este caso, Cuyutlán se convierte progresivamente en el nuevo polo dominante, atrayendo servicios ancla y concentrando las operaciones de mayor escala e intensidad. La intermodalidad ferroviaria se consolida como columna vertebral del sistema ampliado, mientras que las plataformas logísticas externas operan a gran escala como nodos plenamente integrados. Las terminales del recinto histórico evolucionan hacia roles complementarios o especializados, perdiendo su centralidad relativa. Conceptualmente, este escenario corresponde a la consolidación de un polo portuario dominante bajo una lógica port-led avanzada, con reconfiguración geográfica y jerárquica del sistema. No se trata solo de crecer o redistribuir, sino de redefinir la estructura territorial y operativa del puerto. Este modelo permite alcanzar mayores niveles de capacidad efectiva y elasticidad de crecimiento, aunque exige mayor complejidad institucional, inversión y disciplina técnica.

En síntesis, los tres escenarios representan tres niveles de transformación del sistema portuario. El primero describe un sistema que crece en escala sin modificar su arquitectura fundamental. El segundo describe un sistema que modifica su arquitectura operativa sin alterar completamente su centralidad histórica. El tercero describe un sistema que cambia tanto su arquitectura como su centralidad territorial. Esta progresión explica por qué las trayectorias de crecimiento, resiliencia y competitividad divergen hacia 2050. La diferencia no radica únicamente en la demanda futura, sino en el régimen operativo que se decida implementar a partir de la ampliación hacia Cuyutlán.

3.9 Selección del Escenario Desarrollo de la Ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán.

La pregunta sobre cuál de los tres escenarios es el más adecuado para la ampliación en la Laguna de Cuyutlán no puede responderse únicamente en términos de volumen proyectado, sino en función de coherencia técnica, sostenibilidad operativa, viabilidad territorial y posicionamiento estratégico de largo plazo. Desde esa perspectiva integral, el escenario más adecuado para la ampliación es el escenario central, es decir, el modelo de transformación funcional bajo una lógica port-led madura.

El escenario conservador, aunque prudente y técnicamente viable, no aprovecha plenamente el potencial estructural que ofrece la ampliación en un entorno territorial nuevo como Cuyutlán. Si la expansión se limitara a agregar muelles y patios para aliviar la presión inmediata del recinto histórico, el sistema ampliado mantendría la misma arquitectura operativa que hoy muestra signos de tensión. La capacidad nominal aumentaría, pero la capacidad máxima efectiva seguiría condicionada por la evacuación terrestre, la concentración de servicios y la función del patio como regulador forzado. En términos técnicos, se trasladaría el umbral de saturación unos años hacia adelante, pero no se modificaría el régimen operativo que genera variabilidad estructural. Dado que la ampliación en Cuyutlán implica inversión significativa, impacto territorial y complejidad ambiental, utilizarla únicamente como expansión incremental sería subóptimo desde el punto de vista sistémico.

El escenario alto, por su parte, plantea una reconfiguración geográfica completa, donde Cuyutlán se convierte en el nuevo polo dominante del sistema. Este modelo ofrece el mayor potencial de crecimiento y posicionamiento regional, pero también exige una combinación muy exigente de condiciones técnicas, financieras e institucionales. Requiere migración estructural de servicios ancla, intermodalidad ferroviaria dominante desde fases tempranas, plataformas logísticas externas de gran escala plenamente integradas y una gobernanza sistémica consolidada. Además, al desarrollarse en un entorno lagunar sensible, la presión ambiental y social aumenta conforme crece la centralidad operativa. Desde una perspectiva de gestión del riesgo, este escenario implica mayor exposición a desalineaciones entre oferta y demanda durante el periodo de maduración. Técnicamente es posible, pero su implementación exige un grado de coordinación y certidumbre de mercado que debe construirse progresivamente.

El escenario central emerge como el más adecuado porque equilibra transformación estructural con viabilidad gradual. Su base técnica se sustenta en la necesidad de elevar la capacidad máxima efectiva del sistema sin depender exclusivamente del aumento de superficie portuaria. El análisis del comportamiento histórico de Manzanillo muestra que el principal límite no ha sido la productividad de muelle, sino la relación entre descarga intensiva, ocupación de patio y capacidad de evacuación hacia el hinterland. Por ello, la ampliación en Cuyutlán debe diseñarse como instrumento de desacople funcional entre muelle y territorio, no solo como expansión física.

La primera base técnica del escenario central es la redistribución funcional de flujos. Cuyutlán debe absorber parte de los servicios de mayor intensidad operativa, particularmente aquellos asociados a buques de gran tamaño y picos concentrados. Esta redistribución reduce la concentración histórica en pocas terminales y disminuye el riesgo sistémico. No se trata de trasladar volumen por razones administrativas, sino de asignar funciones de acuerdo con diseño, espacio disponible y capacidad de absorción de picos.

La segunda base técnica es el desacople operativo mediante plataformas logísticas externas integradas. El sistema actual muestra que la permanencia promedio en patio se convierte en variable crítica cuando la ocupación supera umbrales sostenibles. Para evitar que la nueva expansión reproduzca este patrón, la regulación logística debe trasladarse parcialmente fuera del recinto inmediato. Plataformas conectadas por corredores dedicados o por intermodalidad ferroviaria permiten reducir la ocupación interna y mantener la rotación del patio dentro de rangos eficientes. Esto incrementa la proporción de capacidad efectiva respecto a la nominal.

La tercera base técnica es la consolidación estructural de la intermodalidad. En el escenario central, el ferrocarril no sustituye totalmente a la carretera, pero sí adquiere un peso significativo en la evacuación de volúmenes en bloque. La sincronización entre arribos marítimos y ventanas ferroviarias reduce la acumulación temporal en patio y disminuye la variabilidad. Esta reducción de variabilidad es clave, ya que la experiencia internacional demuestra que los sistemas logísticos pueden manejar altos volúmenes promedio siempre que la dispersión temporal sea controlada.

La cuarta base técnica es la gobernanza sistémica. Un modelo port-led maduro requiere coordinación entre autoridad portuaria, operadores terminales, sistema ferroviario, aduanas y transporte terrestre. Sin esta coordinación, el sistema ampliado podría fragmentarse en subsistemas que optimizan localmente pero no globalmente. La ampliación en Cuyutlán es una oportunidad para diseñar mecanismos de coordinación desde el inicio, evitando la replicación de asimetrías operativas existentes.

Finalmente, la adecuación del escenario central se justifica también por criterios de sostenibilidad territorial y ambiental. Un modelo redistribuidor y desacoplado permite gestionar

mejor el impacto en el entorno lagunar, ya que evita concentraciones extremas y facilita planificación escalonada del crecimiento. En lugar de convertir a Cuyutlán inmediatamente en un polo dominante con presión máxima desde etapas tempranas, el sistema evoluciona de manera progresiva, ajustando su escala conforme madura la infraestructura y se consolida la integración logística.

En conclusión, el escenario central es el más adecuado para la ampliación en la Laguna de Cuyutlán porque transforma el régimen operativo del sistema sin exigir una redefinición abrupta de su centralidad. Sus bases técnicas se apoyan en redistribución funcional, desacople logístico, intermodalidad estructural y gobernanza integrada. Este modelo eleva la capacidad máxima efectiva, reduce la variabilidad operativa y permite sostener crecimiento hacia 2050 con mayor resiliencia y menor riesgo estructural, manteniendo al mismo tiempo la flexibilidad para evolucionar hacia un esquema dominante si las condiciones futuras lo justifican.

3.10 Lineamientos de Implementación Estratégica

La conveniencia de adoptar el escenario central como base para la ampliación en la Laguna de Cuyutlán— la recomendación técnica es clara: implementar el escenario central como marco estructural de diseño y ejecución, pero con arquitectura preparada para escalar hacia el escenario alto si las condiciones de mercado lo permiten.

No es recomendable ejecutar la ampliación bajo lógica conservadora, porque implicaría desaprovechar una oportunidad histórica de reorganización sistémica. Tampoco es recomendable diseñarla desde el inicio como polo dominante pleno, porque ello elevaría innecesariamente el riesgo financiero, institucional y ambiental en etapas tempranas. La estrategia óptima es estructurar la ampliación como un modelo port-led maduro y escalable.

A continuación, se describe técnicamente esta recomendación.

El sistema actual de Manzanillo ha mostrado que el principal límite no es la productividad marítima, sino la relación entre intensidad de descarga, ocupación de patio y evacuación terrestre. Por tanto, cualquier ampliación que no modifique esa relación estructural terminará reproduciendo las tensiones actuales en un umbral más alto. El escenario central aborda precisamente ese problema: no solo agrega muelle y patio, sino que introduce desacople funcional mediante plataformas externas e intermodalidad coordinada. Esa es la base técnica que realmente eleva la capacidad máxima efectiva.

Sin embargo, diseñar Cuyutlán desde el inicio como polo dominante implicaría forzar una migración estructural de servicios ancla antes de que la red logística ampliada esté completamente consolidada. La experiencia internacional muestra que los cambios de centralidad requieren maduración operativa, estabilidad institucional y certidumbre comercial. Intentar

acelerar esa transición puede generar sobrecapacidad temporal, subutilización inicial y presión financiera innecesaria.

Por ello, la recomendación es adoptar una estrategia de tres capas.

- Primero, diseñar la infraestructura con estándares compatibles con el escenario alto, aunque la operación inicial corresponda al escenario central. Esto significa prever profundidades, configuraciones de muelle, reservas territoriales y conectividad intermodal que permitan escalar sin rediseños estructurales posteriores.

- Segundo, ejecutar la integración logística desde el inicio bajo principios port-led. Esto implica que la ampliación no debe operar como recinto aislado. Debe incorporar desde su primera fase plataformas externas conectadas, coordinación ferroviaria y sistemas de gestión de flujo. La intermodalidad no debe agregarse como mejora posterior, sino como componente estructural del diseño.

- Tercero, establecer métricas de transición que permitan evaluar cuándo el sistema está preparado para evolucionar hacia un modelo más dominante. Estas métricas deberían incluir ocupación promedio sostenible, participación ferroviaria, variabilidad en tiempos de despacho, nivel de concentración por terminal y estabilidad en programación marítima. Si estos indicadores muestran madurez sistémica, entonces la migración hacia una mayor centralidad en Cuyutlán puede realizarse con menor riesgo.

Desde la perspectiva ambiental y territorial, esta recomendación también es coherente. Un desarrollo escalonado permite ajustar medidas de mitigación, monitoreo y gobernanza conforme crece el volumen, reduciendo conflictos sociales y ambientales en un entorno lagunar sensible.

En términos estratégicos, la recomendación puede resumirse así: construir para el escenario alto, operar inicialmente bajo el escenario central y evitar caer en el escenario conservador.

Esta estrategia maximiza flexibilidad, reduce riesgo estructural y permite que el sistema Manzanillo–Cuyutlán evolucione de manera controlada hacia su máximo potencial hacia 2050.

3.10.1 Ampliación del Sistema Manzanillo–Cuyutlán bajo Enfoque Port-Led Escalable

La ampliación hacia la Laguna de Cuyutlán constituye una intervención estructural que definirá el régimen operativo del sistema portuario hacia 2050. En consecuencia, su implementación no debe entenderse como un proyecto de infraestructura aislado, sino como un

proceso de transformación sistémica escalonada. Los siguientes lineamientos estratégicos establecen el marco técnico bajo el cual la expansión puede maximizar su capacidad efectiva, reducir riesgos estructurales y preservar flexibilidad de evolución futura.

El principio rector es claro: diseñar con estándares compatibles con el escenario alto, operar inicialmente bajo el escenario central y evitar replicar un modelo conservador incremental.

3.10.1.1 Diseño estructural con escalabilidad incorporada

El primer lineamiento consiste en garantizar que la infraestructura marítima y terrestre de Cuyutlán se diseñe con parámetros técnicos compatibles con una futura centralidad dominante, aunque la operación inicial responda a un esquema redistribuidor.

Esto implica que el dimensionamiento de dársenas, calados, configuraciones de muelle, áreas de respaldo y reservas territoriales no debe limitarse al volumen proyectado en la fase inicial, sino contemplar la posibilidad de crecimiento sostenido a largo plazo. La infraestructura básica debe ser robusta desde el origen para evitar rediseños costosos o restricciones estructurales en etapas posteriores.

La planificación física debe prever conectividad intermodal directa, corredores dedicados y espacios para expansión logística externa. La escalabilidad no es solo capacidad adicional, sino posibilidad de transformación funcional sin fricciones estructurales.

3.10.1.2 Implementación temprana del desacople funcional

El segundo lineamiento estratégico es incorporar desde la primera fase de operación el desacople entre muelle, patio y hinterland. La experiencia operativa de Manzanillo demuestra que la capacidad efectiva está determinada por la relación entre intensidad de descarga y evacuación terrestre.

Por ello, la ampliación no debe operar como recinto aislado que acumula inventario, sino como nodo de tránsito integrado a una red logística ampliada. Esto exige que las plataformas externas, los corredores de conexión y la coordinación intermodal estén operativos desde etapas tempranas, incluso si el volumen inicial no exige su máxima capacidad.

El desacople temprano reduce el riesgo de que el nuevo recinto reproduzca patrones de saturación estructural a mediano plazo.

3.10.1.3 Consolidación progresiva de la intermodalidad estructural

La intermodalidad ferroviaria debe concebirse como elemento estructural del sistema ampliado y no como mejora posterior. La coordinación entre ventanas marítimas y ferroviarias permite reducir acumulación en patio y disminuir variabilidad operativa.

El lineamiento estratégico consiste en establecer metas progresivas de participación ferroviaria, acompañadas de infraestructura dedicada y sistemas de programación integrados. La carretera continuará siendo relevante, pero su papel debe ser gestionado mediante mecanismos de regulación de flujo y control de citas que reduzcan concentraciones temporales.

Un sistema con mayor participación intermodal es más resiliente y menos dependiente de condiciones urbanas o congestión externa.

3.10.1.4 Redistribución funcional planificada de servicios

La ampliación en Cuyutlán debe incorporar una estrategia deliberada de redistribución funcional de servicios. Esto no implica traslado forzado de volúmenes, sino asignación coherente de flujos según intensidad operativa, requerimientos de espacio y compatibilidad logística.

Los servicios asociados a descargas de alta intensidad o mayor variabilidad pueden concentrarse progresivamente en el nuevo polo, mientras que las terminales históricas estabilizan su operación en rangos sostenibles. Esta redistribución reduce concentración de riesgo y mejora la resiliencia sistémica.

La planificación debe contemplar mecanismos de transición ordenada, evitando disrupciones comerciales innecesarias.

3.10.1.5 Gobernanza sistémica integrada

La ampliación solo alcanzará su potencial bajo un esquema de gobernanza coordinado. Esto implica articulación entre autoridad portuaria, operadores de terminal, sistema ferroviario, autoridades aduaneras y operadores logísticos.

El lineamiento estratégico consiste en establecer un marco institucional que permita gestión sistémica de ventanas operativas, contingencias y planificación de crecimiento. La coordinación debe centrarse en indicadores globales de desempeño, no solo en métricas individuales por terminal.

Sin gobernanza integrada, el sistema ampliado corre el riesgo de fragmentarse en subsistemas que optimizan localmente sin mejorar el desempeño global.

3.10.1.6 Gestión ambiental y social como componente estructural

Dado que la ampliación se desarrolla en un entorno lagunar sensible, la viabilidad ambiental y social no puede considerarse un requisito accesorio. Debe integrarse desde el diseño como condición estructural del proyecto.

El lineamiento estratégico consiste en implementar monitoreo ambiental continuo, modelaciones hidrodinámicas actualizadas, programas de compensación ecológica y mecanismos de diálogo comunitario permanente. La legitimidad social y ambiental es un activo operativo de largo plazo, no un requisito administrativo.

La gestión ambiental adecuada reduce riesgo de interrupciones futuras y fortalece la estabilidad institucional del sistema ampliado.

3.10.1.7 Implementación escalonada con métricas de transición

La estrategia óptima no es ejecutar inmediatamente el escenario alto, sino operar bajo un modelo central escalable. Para ello, deben definirse métricas objetivas que indiquen cuándo el sistema está preparado para evolucionar hacia una mayor centralidad en Cuyutlán.

Estas métricas pueden incluir niveles sostenibles de ocupación de patio, participación ferroviaria consolidada, reducción de variabilidad en tiempos de despacho y estabilidad en programación marítima. Cuando estos indicadores demuestren madurez operativa, la expansión hacia un modelo dominante podrá realizarse con menor riesgo estructural.

3.10.1.8 Coherencia financiera y control de riesgo

La ampliación debe planificarse bajo un esquema financiero escalonado que evite sobrecapacidad en fases tempranas. El ritmo de inversión debe alinearse con la maduración de la demanda y la consolidación logística.

La flexibilidad financiera es un componente estratégico. Permite ajustar fases de expansión sin comprometer sostenibilidad fiscal o financiera del sistema.

3.10.1.9 Conclusión Estratégica

Los lineamientos de implementación estratégica establecen que la ampliación en Cuyutlán debe concebirse como transformación sistémica escalable. Diseñar con visión de polo dominante, operar inicialmente como redistribuidor port-led y evitar la reproducción de un modelo incremental son los principios que maximizan capacidad efectiva, resiliencia y competitividad hacia 2050.

La decisión no es únicamente cuánto construir, sino cómo organizar el sistema para crecer sin reproducir límites estructurales. Bajo estos lineamientos, el sistema Manzanillo–Cuyutlán puede evolucionar de manera ordenada hacia su máximo potencial logístico y territorial.

4.0 DIAGNÓSTICO DE LA PROPUESTA ORIGINAL DE DESARROLLO PORTUARIO.

4.1 Localización del proyecto y situación actual

4.1.1 Ambiente Natural.

La ampliación del puerto de Manzanillo se plantea desarrollarla en la Laguna de Cuyutlán, al sur de la zona costera de la ciudad de Manzanillo. Dicha Laguna muestra una extensión aproximada de 35 km de longitud y 6 km en su parte más ancha. La Laguna tiene como característica geográfica distintiva, la separación en los cuatro vasos, delimitados por barreras físicas – naturales y artificiales, lo que permite el intercambio de líquido y arrastre de sedimentos entre un vaso y otro. Estas barreras, ya sean de origen natural o antrópica, definen variaciones respecto a la influencia de los ciclos de marea, así como áreas de captación de escurrimientos continentales, y características batimétricas específicas, lo que influye en el intercambio con las aguas marinas costeras adyacentes. Los vasos de captación se muestran en la Figura 4.1, ubicándose las áreas propuestas para la ampliación del puerto dentro del Vaso II.

Figura 4.1 Vasos de la Laguna de Cuyutlán.

Fuente: Elaboración propia con base en Google Earth, 2026.

4.1.2 Infraestructura Existente.

Hoy en día, en el Vaso II de la Laguna ya existen instalaciones para la manipulación de fluidos. En junio de 2009, la SCT otorgó el Título de Concesión en favor de la empresa KMS, para el

uso y aprovechamiento de una zona marítima para la construcción y operación de una terminal portuaria de uso particular, destinada a la recepción, almacenamiento y regasificación de GNL.

La terminal, entró en operación en 2012, y abastece de Gas Natural a la termoeléctrica de la CFE en Manzanillo vía ducto, así como al centro de distribución nacional en Guadalajara. A diferencia de otro tipo de terminales, las estructuras de atraque de KMS están compuestas por duques de alba y una plataforma de operaciones, la cual le permite recibir embarcaciones de hasta 14 metros de calado y 340 metros de eslora.

Figura 4.2 Terminal de Gas Natural Licuado de KMS.

Fuente: Terminal KMS de GNL, S. de R.L. de C.V., 2026.

Para garantizar el acceso de los buques al vaso II de la Laguna, en 2012 se finalizaron las obras de adecuación del Canal de Tepalcates, el cual dispone de una longitud de 1,750 metros, una plantilla de 250 metros entre balizas y una profundidad de unos 15 metros. Las protecciones del canal se componen de dos escolleras de material pétreo y de elementos prefabricados de concreto, perpendiculares a la línea de playa.

Asimismo, existe una protección marginal de 3 kilómetros, que tiene por objeto salvaguardar de la erosión ocasionada por el oleaje continua a ambas márgenes del canal, así como evitar su azolvamiento. De manera complementaria a la adecuación del canal, se llevó a cabo un dragado de la dársena de ciaboga (la cual dispone de un diámetro de 600 metros) y de la dársena de operación de la terminal de KMS (la cual dispone cuenta con un abocinamiento de 600 por 250 metros), de cara a garantizar la navegabilidad y maniobrabilidad de los buques atendidos.

Figura 4.3 Infraestructura Existente en el Vaso II.

Fuente: Elaboración propia con base en Google Earth, 2026.

Existe otra terminal operativa en la barra de campos, denominada Zeta Gas del Pacífico, la cual da servicio de descarga a buques de Gas Licuado del Petróleo y Gas propano. La terminal dispone de un sistema basado en la recepción a través de un campo de monoboyas, transportando posteriormente la mercancía hasta las esferas de almacenamiento. A diferencia del caso de KMS, la distribución de Zeta Gas se produce mediante Auto-tanques.

Aprovechando los cambios derivados de la reforma energética mediante los cuales se abre la posibilidad de participar en los negocios de transporte, almacenamiento, compraventa y distribución de todo tipo de combustibles, hay dos empresas que están desarrollando sus proyectos, siendo el proyecto de Porter y el de Logistica de Fluidos y Graneles (LFG).

A nivel de accesos terrestres a la Laguna, cabe remarcar que la SCT construyó un libramiento ferroviario que comunica la barra de campos con el puerto actual, disponiendo de diferentes zonas con playas de vías para las operaciones de FERROMEX.

Figura 4.4 Infraestructura Ferroviaria Existente en el Vaso II.

Fuente: Elaboración propia con base en Google Earth, 2026.

En cuanto al tema de la conexión por carretera, actualmente existe la carretera No. 200 que se conecta con el viaducto y este a la carretera costera Campos–Cuyutlán, sin embargo, estas vialidades tienen solo dos carriles (uno por sentido), cosa que podría producir congestionamientos en un futuro, debido a la alta demanda de utilización del autotransporte para el ingreso y salida de la carga por la utilización de vehículos urbanos de Manzanillo.

Asimismo, se han identificado una serie de condicionantes que deberán ser considerados a la hora de definir la configuración de las distintas alternativas de desarrollo, especialmente a nivel de ubicación en la Laguna, dado el impacto directo de las condiciones de batimetría y oleaje, así como por la presencia de elementos/barreras físicas como son las torres de transmisión de la CFE, las islas naturales del centro del vaso (isla cocodrilo I y II) y los manglares localizados en las márgenes de la laguna. Dichos condicionantes deben ser considerados para dimensionar las características y la inversión del dragado necesario, así como para dimensionar la infraestructura portuaria y los ramales de conectividad terrestre

4.2 Diagnóstico Ambiental Integral

4.2.1 Descripción de los Componentes Bióticos

La Laguna de Cuyutlán es un humedal costero de gran relevancia ecológica en Colima; el sitio Ramsar “Laguna de Cuyutlán (Vasos III y IV)” concentra una porción muy importante de los humedales del estado y se caracteriza por su diversidad de flora y fauna. Por tal motivo, constituye un sistema lagunar costero de tipo estuarino–hipersalino localizado en el litoral del Pacífico mexicano. Desde el punto de vista ecológico, los sistemas lagunares costeros se caracterizan por presentar alta productividad biológica, marcada variabilidad fisicoquímica y elevada sensibilidad a modificaciones hidrológicas. Su funcionamiento depende del equilibrio entre aportes continentales, intercambio marino, evaporación y dinámica sedimentaria.

En términos bióticos, el sistema se organiza en varios “bloques” ecológicos estrechamente conectados: comunidades de manglar y vegetación asociada, productores primarios acuáticos (fitoplancton y vegetación sumergida/macroalgas cuando las condiciones lo permiten), comunidades bentónicas (invertebrados del fondo), peces y otros vertebrados acuáticos, herpetofauna (reptiles y anfibios), y una avifauna particularmente diversa por la función del humedal como sitio de alimentación, descanso y reproducción.

4.2.2 Funcionamiento ecológico del sistema lagunar

Los sistemas lagunares costeros operan como ecosistemas de transición entre ambientes marinos y continentales. En el caso de Cuyutlán, la conectividad hidrológica parcial con el mar y la subdivisión en vasos generan gradientes espaciales de salinidad, oxigenación y disponibilidad de nutrientes.

Desde el punto de vista técnico, la laguna puede clasificarse como un sistema de circulación restringida en ciertos vasos, lo que implica tiempos de residencia del agua relativamente elevados. Este parámetro es crítico, ya que determina la capacidad de dilución de contaminantes, la estabilidad térmica y la susceptibilidad a procesos de eutrofización.

La productividad primaria constituye el motor energético del sistema. La descomposición de materia orgánica proveniente de manglares y vegetación halófita genera detritos que sustentan cadenas tróficas detritívoras. Este mecanismo es típico de humedales costeros y explica su elevada eficiencia ecológica.

El equilibrio del sistema depende de la estabilidad de los siguientes procesos: intercambio hídrico, balance salino, reciclaje de nutrientes, dinámica sedimentaria y conectividad ecológica.

4.2.3 Componentes Bióticos de la Laguna de Cuyutlán

4.2.3.1 Vegetación estructural y primaria

Los manglares representan el componente estructural dominante en sectores del sistema lagunar. Estas comunidades están adaptadas a condiciones de inundación periódica y salinidad variable, desarrollando raíces aéreas y mecanismos fisiológicos de exclusión o excreción salina. Técnicamente, los manglares actúan como ingenieros ecosistémicos, modificando el microambiente, reduciendo la energía del oleaje y promoviendo la sedimentación.

En el Vaso II, la cobertura de manglar es más fragmentada en comparación con otros vasos, predominando vegetación halófita adaptada a planicies salinas con alta evaporación. Estas comunidades presentan adaptaciones morfofisiológicas como suculencia y reducción foliar para tolerar estrés osmótico.

El fitoplancton y microalgas bentónicas constituyen la base primaria de producción acuática. Su biomasa responde directamente a disponibilidad de nitrógeno y fósforo, temperatura y radiación solar. La variabilidad estacional puede generar pulsos productivos significativos.

Desde el punto de vista técnico, la concentración de clorofila-a es un indicador relevante de productividad y posible eutrofización.

4.2.3.2 Comunidades bentónicas

El bentos del sistema se desarrolla sobre sedimentos predominantemente finos, con fracciones limosas y arcillosas que favorecen acumulación de materia orgánica. Estos sedimentos presentan baja permeabilidad, lo que puede generar gradientes verticales de oxígeno y zonas anóxicas en condiciones de alta carga orgánica.

Los organismos bentónicos cumplen funciones de bioturbación, es decir, remueven y oxigenan sedimentos, contribuyendo al reciclaje de nutrientes. La diversidad de poliquetos, moluscos y crustáceos está estrechamente asociada a la calidad ambiental.

En sistemas con perturbación física frecuente o hipoxia, se observa dominancia de especies oportunistas de ciclo corto, lo que constituye un indicador de estrés ambiental.

4.2.3.3 Ictiofauna y dinámica trófica

El sistema lagunar funciona como área de reclutamiento para especies marino-estuarinas. Las zonas someras y protegidas ofrecen refugio contra depredadores y condiciones favorables para crecimiento juvenil.

Desde el punto de vista ecológico, la diversidad ictiológica depende de la estabilidad salina y conectividad con el mar. Cambios abruptos en salinidad o disminución de oxígeno pueden generar mortalidad o desplazamiento.

La dinámica trófica integra fitoplancton, zooplancton, bentos e ictiofauna, formando una red interdependiente. La alteración de cualquiera de estos componentes impacta niveles superiores, incluyendo aves piscívoras.

4.2.3.4 Avifauna y función ecosistémica

Las aves acuáticas utilizan el sistema como sitio de alimentación, descanso y, en algunos casos, reproducción. Las planicies someras del Vaso II ofrecen condiciones óptimas para aves playeras que dependen de invertebrados bentónicos.

Desde el punto de vista técnico, la abundancia y riqueza de aves constituyen indicadores integradores del estado del ecosistema, ya que reflejan disponibilidad trófica y estabilidad hidrológica.

4.2.3.5 Reptiles y otros vertebrados

La presencia de reptiles estuarinos indica conectividad ecológica funcional. Estos organismos ocupan niveles tróficos superiores y su permanencia depende de disponibilidad de presas y hábitat estructural adecuado.

4.2.4 Diagnóstico específico del Vaso II

El Vaso II presenta profundidad reducida y alta evaporación, lo que genera tendencia natural a la hipersalinidad en periodos secos. Desde el punto de vista hidrológico, la limitada renovación hídrica incrementa el tiempo de residencia del agua, amplificando efectos de aportes externos.

La comunidad biológica muestra adaptaciones a condiciones fluctuantes; sin embargo, la resiliencia del sistema es limitada ante perturbaciones acumulativas.

La estructura bentónica y la composición de aves sugieren que el sistema mantiene funcionalidad, aunque con signos potenciales de simplificación en sectores sujetos a mayor perturbación.

4.2.4.1 Problemática ambiental actual

a. **Alteraciones hidrodinámicas:** Las modificaciones en conectividad entre vasos, dragados regionales y obras de infraestructura pueden alterar la circulación interna. Técnicamente, cambios en régimen de mezcla influyen en distribución de salinidad y oxígeno, afectando procesos ecológicos.

b. **Incremento de salinidad:** En sistemas someros, la evaporación puede superar aportes hídricos, generando hipersalinidad. Este fenómeno reduce diversidad biológica y favorece especies tolerantes, disminuyendo complejidad ecológica.

c. **Eutrofización:** Aportes de nutrientes inducen crecimiento fitoplanctónico excesivo. La descomposición subsecuente consume oxígeno, pudiendo generar hipoxia o anoxia. Estos procesos afectan principalmente bentos e ictiofauna juvenil.

d. **Fragmentación de hábitat:** La reducción de vegetación ribereña disminuye conectividad ecológica y capacidad de amortiguamiento ante eventos extremos.

Con base en estructura biológica, procesos ecológicos y presiones identificadas, el Vaso II presenta condición ecológica funcional pero vulnerable. El sistema muestra resiliencia moderada, condicionada a mantener conectividad y control de aportes externos.

El estado se clasifica como intermedio con tendencia a degradación si las presiones hidrológicas y de calidad de agua aumentan.

4.2.5 El Manglar en la Laguna de Cuyutlán

El manglar es uno de los ecosistemas más relevantes dentro de los humedales costeros tropicales y subtropicales. Se desarrolla en zonas intermareales protegidas, donde convergen procesos marinos y continentales, y donde los suelos presentan condiciones de inundación periódica, alta salinidad y baja disponibilidad de oxígeno.

Desde el punto de vista ecológico, los manglares cumplen funciones estructurales y funcionales críticas. Actúan como ingenieros ecosistémicos al modificar el ambiente físico mediante la retención de sedimentos, reducción de energía hidrodinámica y estabilización de suelos. Asimismo, constituyen uno de los sistemas más eficientes en captura y almacenamiento de carbono, particularmente en sus suelos orgánicos saturados.

En sistemas lagunares como la Laguna de Cuyutlán, el manglar representa el principal componente vegetal estructural que vincula el medio terrestre con el acuático y que sostiene redes tróficas basadas en detritos.

En la Laguna de Cuyutlán, el manglar se distribuye en sectores con condiciones adecuadas de inundación y salinidad moderada, principalmente en zonas con mayor estabilidad hidrológica y cercanas a conexiones con el mar o con aportes de agua dulce estacional.

Las especies dominantes en el sistema corresponden a las típicas del Pacífico mexicano:

- *Rhizophora mangle* (mangle rojo), asociada a zonas de mayor influencia hídrica.
- *Laguncularia racemosa* (mangle blanco), presente en sectores ligeramente más elevados.
- *Avicennia germinans* (mangle negro), en zonas con mayor salinidad y menor frecuencia de inundación.
- *Conocarpus erectus* (botoncillo), en áreas de transición hacia ambientes más secos.

La estructura del manglar en Cuyutlán puede clasificarse como manglar ribereño y manglar de cuenca, dependiendo de su ubicación y régimen hídrico. En sectores con mayor permanencia de agua se desarrollan comunidades más densas y con mayor altura arbórea, mientras que en zonas con alta evaporación y salinidad extrema la vegetación tiende a ser más baja y menos diversa.

El manglar del sistema cumple funciones clave como área de refugio y crianza para peces y crustáceos juveniles, hábitat para aves residentes y migratorias, protección contra erosión y filtración de nutrientes provenientes de escorrentía superficial.

4.2.5.1 Estado general del manglar en la Laguna de Cuyutlán

Históricamente, el sistema lagunar ha experimentado reducción y fragmentación de cobertura de manglar asociadas a procesos de expansión urbana, infraestructura portuaria, modificación de conectividad hídrica y cambios de uso de suelo.

Las alteraciones de la Laguna derivadas de las actividades productivas, así como de las diferentes obras de infraestructura, han afectado a la cobertura del manglar a lo largo de los años. A continuación, se presentan dos imágenes comparativas de la evolución de la superficie de manglar entre 1971 y 2010.

Desde el punto de vista técnico, la fragmentación reduce conectividad ecológica, limita flujo genético entre poblaciones y disminuye resiliencia ante perturbaciones. Asimismo, alteraciones hidrológicas que modifiquen el régimen natural de inundación pueden inducir estrés fisiológico en las especies de manglar, manifestado en reducción de crecimiento, mortalidad localizada o sustitución por vegetación halófita.

La estabilidad del manglar depende de tres variables fundamentales: régimen hídrico adecuado, salinidad dentro de rangos tolerables y estabilidad del sustrato.

4.2.6 El manglar en el Vaso II.

4.2.6.1 Distribución y características estructurales.

En el Vaso II, la cobertura de manglar es más limitada y fragmentada en comparación con otros vasos del sistema. Esto se debe principalmente a las condiciones particulares de este vaso, caracterizado por baja profundidad, alta evaporación y tendencia a hipersalinidad estacional.

Las comunidades presentes en el Vaso II suelen desarrollarse en bordes y zonas de transición, donde la salinidad no alcanza niveles extremos. Predomina el mangle blanco y el mangle negro en sectores con mayor exposición a variaciones salinas. El mangle rojo, que requiere mayor influencia hídrica permanente, se presenta en menor proporción.

La estructura vertical del manglar en el Vaso II tiende a ser de menor altura y densidad, lo cual es consistente con condiciones ambientales más restrictivas.

Aunque su extensión es menor, el manglar del Vaso II desempeña funciones ecológicas esenciales. Proporciona microhábitats para invertebrados asociados a raíces, refugio para juveniles de peces y zonas de percha y anidación para aves.

El aporte de hojarasca y detritos constituye una fuente primaria de carbono orgánico que alimenta la red trófica bentónica y contribuye al reciclaje de nutrientes.

Desde el punto de vista hidrológico, el manglar actúa como zona de amortiguamiento frente a fluctuaciones extremas de salinidad y protege bordes lagunares contra erosión.

4.2.6.2 Vulnerabilidad del manglar en el Vaso II.

El manglar en el Vaso II presenta alta vulnerabilidad debido a:

- La tendencia natural a hipersalinidad en periodos de estiaje, que puede superar la tolerancia fisiológica de algunas especies.
- La posible alteración de conectividad hídrica derivada de infraestructura regional, que modifica el régimen de inundación necesario para el mantenimiento del ecosistema.
- La fragmentación espacial, que reduce la resiliencia frente a perturbaciones climáticas o antrópicas.
- La acumulación de sedimentos finos y materia orgánica en condiciones de baja renovación, que puede generar estrés radicular por anoxia.

Desde un enfoque técnico, la alteración del régimen hídrico es el factor de mayor riesgo para el manglar del Vaso II, ya que este ecosistema depende estrictamente de ciclos periódicos de inundación y renovación de agua.

Con base en condiciones hidrológicas, estructura vegetal y presiones identificadas, el manglar del Vaso II puede considerarse funcional pero vulnerable. Su persistencia depende del mantenimiento de conectividad hídrica adecuada, control de aportes contaminantes y prevención de nuevas fragmentaciones.

El estado puede clasificarse como intermedio, con tendencia a deterioro en ausencia de manejo específico orientado a restauración hidrológica y conservación de bordes vegetados.

En resumen, el manglar de la Laguna de Cuyutlán constituye el principal soporte estructural y funcional del ecosistema lagunar. En el Vaso II, aunque su cobertura es más limitada, cumple funciones ecológicas estratégicas y representa un componente crítico para la estabilidad ambiental del sistema.

La preservación del régimen hidrológico natural y la reducción de presiones antrópicas son condiciones indispensables para mantener su integridad ecológica y garantizar la continuidad de los servicios ecosistémicos asociados.

4.2.7 Descripción de los Componentes Abióticos

La Laguna de Cuyutlán constituye un sistema lagunar costero del Pacífico mexicano cuya configuración física y funcionamiento ecológico están determinados por un conjunto de componentes abióticos interrelacionados. Estos incluyen la geomorfología, geología, batimetría, hidrodinámica, régimen climático, calidad del agua, características fisicoquímicas, sedimentología y procesos de intercambio marino-continental. El análisis integral de estos elementos es indispensable para comprender la dinámica natural del sistema y su sensibilidad ante intervenciones antrópicas.

4.2.7.1 Geomorfología y configuración espacial

La Laguna de Cuyutlán se ubica en una planicie costera aluvial, separada del océano Pacífico por una barra litoral arenosa relativamente estrecha. El sistema presenta forma elongada paralela a la línea de costa y está subdividido en varios vasos interconectados, con diferencias en profundidad, conectividad y régimen salino.

Geomorfológicamente, el sistema corresponde a una laguna costera de barrera, formada por la acumulación progresiva de sedimentos marinos y continentales que aislaron antiguos brazos marinos. La barra arenosa que la separa del océano actúa como control natural de

intercambio hidráulico, mientras que las conexiones artificiales o naturales determinan el grado de influencia marina.

El Vaso II, en particular, presenta morfología predominantemente somera, con extensas planicies submareales y presencia de islotes centrales formados por acumulación sedimentaria. Esta condición geomorfológica condiciona su comportamiento hidrodinámico y su alta sensibilidad a cambios en profundidad o circulación.

4.2.7.2 Geología y sustrato

El sustrato de la laguna está compuesto principalmente por sedimentos cuaternarios recientes de origen marino, fluvial y lagunar. Predominan materiales finos como limos y arcillas con alto contenido de materia orgánica, especialmente en zonas de baja energía hidráulica.

La geología regional corresponde a depósitos aluviales costeros sobre basamento volcánico más antiguo. La presencia de sedimentos blandos y saturados determina baja capacidad portante natural del suelo y alta susceptibilidad a procesos de consolidación y asentamiento bajo cargas adicionales.

Desde el punto de vista geoquímico, los sedimentos pueden presentar condiciones reductoras en capas profundas debido a acumulación de materia orgánica y baja oxigenación, lo cual influye en ciclos biogeoquímicos de nitrógeno, fósforo y azufre.

4.2.7.3 Batimetría y morfología del fondo

La laguna se caracteriza por profundidades relativamente bajas, que en muchos sectores no superan los pocos metros. La batimetría es heterogénea, con áreas más profundas asociadas a antiguos canales o zonas de mayor intercambio, y extensas planicies someras que quedan parcialmente expuestas en periodos de nivel bajo.

El Vaso II presenta particularmente una batimetría muy somera, lo que incrementa su vulnerabilidad a evaporación, variaciones térmicas y acumulación de sedimentos. Esta condición influye directamente en la dinámica de mezcla vertical y en el comportamiento térmico del cuerpo de agua.

La morfología del fondo está sujeta a procesos de sedimentación continua, redistribución por corrientes internas y aportes fluviales episódicos durante temporada de lluvias.

4.2.7.4 Hidrodinámica y circulación

La hidrodinámica de la Laguna de Cuyutlán está determinada por una combinación de factores: intercambio con el océano, mareas, viento, evaporación y aportes pluviales. La amplitud

de marea en el Pacífico mexicano es relativamente moderada; sin embargo, su efecto se amplifica o atenúa dependiendo del grado de conectividad entre vasos.

En sectores con conectividad restringida, como el Vaso II, el tiempo de residencia del agua tiende a ser mayor, lo que implica menor capacidad de dilución de contaminantes y mayor susceptibilidad a estratificación salina y térmica.

El viento desempeña un papel importante en la generación de corrientes superficiales y mezcla vertical, especialmente en cuerpos someros. En temporada seca, la evaporación intensa incrementa la salinidad y densidad del agua superficial, pudiendo inducir circulación por gradientes de densidad.

4.2.7.5 Régimen climático

El clima de la región es tropical subhúmedo con temporada de lluvias en verano y estiaje prolongado durante el invierno y primavera. Las temperaturas medias anuales son elevadas, con alta radiación solar.

La evaporación potencial anual es significativa y, en combinación con la limitada renovación hídrica en ciertos vasos, genera incrementos estacionales de salinidad. Durante la temporada de lluvias, los aportes pluviales reducen temporalmente la salinidad y aumentan la turbidez por escorrentía.

Eventos extremos como tormentas tropicales y huracanes pueden generar cambios abruptos en niveles de agua, redistribución de sedimentos y alteraciones temporales en calidad del agua.

4.2.7.6 Calidad del agua y parámetros fisicoquímicos

La calidad del agua en la Laguna de Cuyutlán está determinada por la interacción entre evaporación, intercambio marino y aportes continentales. Los principales parámetros fisicoquímicos de interés incluyen salinidad, temperatura, oxígeno disuelto, pH, turbidez y concentración de nutrientes.

La salinidad presenta variaciones espaciales y estacionales. En vasos con menor renovación, puede alcanzar valores hipersalinos durante estiaje. La temperatura superficial tiende a ser alta debido a la poca profundidad y alta radiación solar.

El oxígeno disuelto puede presentar variabilidad diaria significativa asociada a actividad fotosintética y respiración biológica, y puede disminuir en zonas con alta carga orgánica o bajo intercambio.

La turbidez depende de resuspensión de sedimentos finos por viento o corrientes, así como de aportes pluviales.

4.2.7.7 Procesos sedimentarios

El sistema lagunar funciona como zona de depósito de sedimentos finos transportados desde cuencas continentales y redistribuidos por dinámica marina. La baja energía hidráulica en sectores internos favorece acumulación de limos y arcillas.

Los islotes centrales del Vaso II son producto de procesos de acumulación progresiva y desempeñan función geomorfológica relevante al modificar corrientes internas y patrones de sedimentación.

La alteración de estos procesos, por ejemplo mediante dragado o modificación geométrica, puede desencadenar cambios en el balance sedimentario y generar erosión o colmatación en nuevas áreas.

4.2.7.8 Balance salino y evaporación

El balance salino es un componente crítico del sistema. En periodos secos, la evaporación supera aportes de agua dulce, concentrando sales en el cuerpo lagunar. En vasos con baja renovación, este proceso puede inducir hipersalinidad.

La estabilidad del sistema depende de la relación entre evaporación, intercambio marino y aportes pluviales. Cambios en conectividad o profundidad pueden modificar este balance.

4.2.7.9 Nivel del mar y variabilidad hidrológica

La laguna está sujeta a fluctuaciones de nivel asociadas a mareas, presión atmosférica y eventos meteorológicos extremos. A largo plazo, el aumento del nivel medio del mar representa un factor adicional de presión, que puede modificar gradientes hidráulicos y provocar intrusión salina.

4.2.7.10 Conclusión técnica

Los componentes abióticos de la Laguna de Cuyutlán configuran un sistema físicamente dinámico pero delicado, donde la baja profundidad, la sedimentación fina, la evaporación intensa y la conectividad variable determinan un equilibrio hidrodinámico y geoquímico sensible. El Vaso II, por su carácter somero y restringido, presenta mayor vulnerabilidad ante modificaciones geométricas o hidrológicas.

La comprensión detallada de estos componentes es fundamental para cualquier análisis de impacto, planeación portuaria o estrategia de manejo integral del sistema lagunar.

4.2.7.11 Interacción entre los componentes abióticos de la Laguna de Cuyutlán y la ampliación portuaria en el Vaso II

La ampliación del Puerto de Manzanillo hacia el Vaso II de la Laguna de Cuyutlán implica la modificación directa de un sistema físico caracterizado por baja profundidad, alta evaporación, dinámica sedimentaria fina y conectividad hidrológica limitada. La intervención proyectada, que contempla dragado de profundización, conformación de dársenas, rellenos hidráulicos y construcción de infraestructura rígida, interactúa con cada uno de los componentes abióticos del sistema de manera estructural y no meramente superficial. En este sentido, el análisis debe centrarse en la alteración de procesos físicos fundamentales más que únicamente en la transformación espacial del cuerpo de agua.

a. Interacción con la geomorfología y batimetría

La geomorfología actual del Vaso II responde a un equilibrio natural entre sedimentación fina, evaporación y circulación interna de baja energía. La profundización artificial del vaso para habilitar canales de navegación rompe esta condición somera, generando zonas de mayor profundidad que alteran la distribución natural de gradientes hidráulicos.

La creación de un canal profundo en un sistema originalmente plano puede inducir fenómenos de concentración de flujo, modificando trayectorias de circulación y generando patrones de erosión en áreas previamente estables. Asimismo, la rectificación geométrica del vaso para adecuarlo a radios de giro de buques puede implicar la eliminación de irregularidades naturales que actualmente cumplen funciones de disipación de energía.

El resultado esperado es una transición de un sistema lagunar dominado por energía baja y sedimentación difusa a un sistema parcialmente canalizado, con trayectorias hidráulicas definidas y gradientes artificiales de profundidad.

b. Interacción con la hidrodinámica

La hidrodinámica del Vaso II está condicionada por intercambio restringido y por influencia eólica significativa. La ampliación portuaria introduce tres factores de modificación:

En primer lugar, el aumento de profundidad genera cambios en la estratificación térmica y salina, pudiendo favorecer capas de mayor estabilidad vertical donde disminuye la mezcla natural.

En segundo lugar, la presencia de estructuras rígidas modifica la circulación lateral, generando zonas de recirculación o “zonas muertas” con tiempos de residencia elevados.

En tercer lugar, el tránsito frecuente de embarcaciones de gran calado introduce energía mecánica adicional mediante oleaje inducido y corrientes de hélice, alterando el patrón natural de mezcla superficial.

Estos cambios pueden incrementar la heterogeneidad espacial del sistema y generar microambientes con condiciones fisicoquímicas diferenciadas, algunas potencialmente desfavorables para el equilibrio natural.

c. Interacción con el balance salino

El Vaso II presenta tendencia natural a concentraciones salinas elevadas durante periodos de estiaje debido a evaporación intensa. La modificación geométrica puede alterar el balance salino de dos maneras posibles.

Si la profundización incrementa el intercambio marino, podría reducirse parcialmente la hipersalinidad estacional, pero también introducir agua de mayor densidad que altere la estratificación vertical. Si, por el contrario, se generan compartimentaciones o barreras que limiten circulación transversal, podrían establecerse zonas de mayor concentración salina y tiempos de residencia más largos.

El balance final dependerá de la configuración hidráulica adoptada, pero en ambos casos el régimen salino natural será modificado, con posibles efectos en procesos biogeoquímicos asociados.

d. Interacción con procesos sedimentarios

La laguna funciona como trampa natural de sedimentos finos. El dragado inicial para habilitar el canal implica la remoción masiva de sedimentos blandos con alto contenido de materia orgánica. Durante la fase constructiva, la resuspensión incrementará turbidez y podrá redistribuir partículas finas hacia zonas adyacentes.

Posteriormente, el nuevo equilibrio morfodinámico tenderá a compensar la alteración. Los islotes centrales actualmente actúan como moduladores de flujo y zonas de deposición. Su modificación o eliminación podría alterar el patrón de transporte sedimentario, generando erosión en bordes lagunares o acumulación acelerada en áreas dragadas.

Este proceso implica que el sistema podría requerir dragados de mantenimiento frecuentes, con implicaciones ambientales y económicas acumulativas.

e. Interacción con la calidad del agua

La calidad del agua en sistemas someros depende de la interacción entre producción primaria, respiración, mezcla y renovación. La profundización y el aumento del tiempo de residencia en determinadas áreas pueden favorecer procesos de estratificación térmica y disminución de oxígeno en capas inferiores.

La resuspensión de sedimentos ricos en materia orgánica durante dragado incrementa la demanda bioquímica de oxígeno, pudiendo generar episodios de hipoxia local. En un sistema con limitada renovación, estos eventos pueden prolongarse más que en ambientes abiertos.

Además, el aumento de tráfico marítimo incrementa el riesgo de derrames accidentales, descargas no intencionales y aportes difusos de contaminantes asociados a operación portuaria.

f. Interacción con el régimen climático y eventos extremos

La laguna está expuesta a ciclones y tormentas tropicales que generan variaciones abruptas en nivel del agua y redistribución de sedimentos. La presencia de infraestructura rígida modifica la respuesta del sistema ante estos eventos.

Plataformas y muelles pueden actuar como barreras que reflejen energía de oleaje, generando concentración de esfuerzos en puntos específicos. Asimismo, la modificación del relieve submarino puede alterar la propagación de ondas internas durante eventos extremos.

El diseño debe considerar escenarios de cambio climático y aumento del nivel medio del mar, incorporando márgenes de seguridad hidráulica y estructural.

g. Interacción con la estabilidad geotécnica

Los sedimentos del Vaso II presentan baja resistencia y alta compresibilidad. La colocación de rellenos masivos para plataformas portuarias implica procesos de consolidación que pueden extenderse durante años.

Si no se aplican técnicas adecuadas de mejoramiento de suelos, pueden presentarse asentamientos diferenciales que afecten integridad estructural y generen fracturas en pavimentos, sistemas de drenaje o cimentaciones.

Asimismo, la redistribución de cargas puede inducir cambios en esfuerzos laterales en sedimentos blandos, incrementando riesgo de inestabilidad marginal.

h. Evaluación integrada del cambio físico del sistema

La ampliación portuaria no representa una alteración aislada de un componente abiótico específico; constituye una transformación integral del régimen físico del Vaso II. Se pasa de un sistema dominado por procesos naturales de baja energía, sedimentación difusa y variabilidad salina estacional, a un sistema parcialmente canalizado, con profundidades artificiales, energía inducida por navegación y mantenimiento hidráulico permanente.

La magnitud de este cambio determina que el análisis no pueda limitarse a impactos puntuales, sino que debe evaluar el riesgo de transición de régimen físico del sistema lagunar.

i. Conclusión técnica

La interacción entre los componentes abióticos de la Laguna de Cuyutlán y la ampliación portuaria en el Vaso II es estructural y sistémica. La modificación de geomorfología, hidrodinámica y procesos sedimentarios puede desencadenar ajustes morfodinámicos de largo plazo, alterar el balance salino y modificar la calidad del agua.

Dado que el Vaso II presenta condiciones naturales de alta sensibilidad por su baja profundidad y limitada renovación hídrica, cualquier intervención debe fundamentarse en modelación avanzada, monitoreo continuo y diseño adaptativo, de manera que la ingeniería portuaria se ajuste a los límites físicos del sistema lagunar.

4.3 Diagnóstico de la Propuesta Original de Desarrollo Portuario.

4.3.1 Descripción técnica del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán.

La ampliación del Puerto de Manzanillo hacia la Laguna de Cuyutlán, denominada “Nuevo Puerto Manzanillo-Cuyutlán”, constituye uno de los principales proyectos de infraestructura portuaria en México, promovido por la administración federal y ejecutado bajo coordinación de la Secretaría de Marina (SEMAR). Su propósito es responder al crecimiento sostenido del comercio marítimo internacional y consolidar a México como un nodo logístico competitivo en América Latina y el Pacífico mundial.

Estructuralmente, el proyecto considera la expansión del actual recinto portuario de Manzanillo —que cubre aproximadamente 450 hectáreas— a una superficie de alrededor de 1,800 a 1,880 hectáreas en la Laguna de Cuyutlán, lo que representa casi cuatro veces la extensión actual del puerto. Esta nueva área se ubica principalmente en el Vaso II de la laguna, un cuerpo lagunar somero cuya transformación implicará la construcción de infraestructura terrestre y marítima compleja para soportar operaciones de carga y descarga de gran escala.

La propuesta de ampliación contempla la siguiente infraestructura:

1. El área del Recinto Nuevo Manzanillo Cuyutlán es de 1,880 ha.

2. Terminales Privadas para el manejo de Combustibles

    - Terminal de Petroliferos de LFG
    - Terminal de Petroliferos Porter

3. Terminal de Almacenamiento y Distribución de PEMEX (3.7 millones de barriles de almacenamiento de gasolina y diésel). Contará con tres muelles y tendrá capacidad de recibir hasta cinco buques petroleros

4. Mega Terminales de Contenedores No. 3 y 4, con una superficie de 100 ha cada una. Cada terminal tendrá una capacidad de 2.5 millones de TEU's anuales. Cada terminal tendrá 1,500 m de muelle y podrán recibir hasta 3 megabuques simultáneamente cada una.

5. Instalaciones para la Aduana de Importaciones y estará conectada directamente a las vías de ferrocarril.

6. Contará con una central de emergencia.

7. Un Comando Unificado Marítimo (CUMAR).

8. Una Unidad Naval de Protección Portuaria (UNAPROP)

9. Instalaciones para una Aduana de Exportación

10. Canal de Navegación, con un ancho de 250 m a una profundidad de-17 m y dos dársenas de maniobra (una de 800 m de diámetro y una de 600 m de diámetro) adicionales a la existente.

11. Viaductos elevados para el ferrocarril y auto transporte

12. Terminales especializadas de contenedores No. 5 y 6, en una segunda fase de construcción, con una superficie de 100 ha cada una. Cada terminal tendrá una capacidad de 2.5 millones de TEU's anuales.

Figura 4.9 Propuesta de Ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán.

Fuente: ASIPONA Manzanillo, 2026.

Desde la perspectiva de ingeniería portuaria, la ampliación incluye la construcción de un canal de navegación profundo con dársenas de maniobra para permitir el ingreso y salida segura de buques de gran calado. Este canal será objeto de dragado de profundización y mantenimiento, y se espera que el diseño permita operar embarcaciones tipo Post-Panamax con calados superiores a los existentes en la laguna actual, aunque los valores específicos de calado final dependen de los estudios hidrográficos finales y del proyecto ejecutivo aprobado

La implantación del nuevo puerto comprende varias terminales especializadas: terminales de contenedores con alta capacidad operativa, áreas para carga general, graneles agrícolas, graneles minerales y una terminal especializada para hidrocarburos. De acuerdo con informes oficiales, se proyecta que estas nuevas terminales puedan movilizar hasta 2.5 millones de TEU's por año en una de las terminales especializadas de contenedores, lo cual ampliaría la capacidad total del puerto de los actuales 4.7 millones de TEU's anuales hasta cerca de 10 millones de TEU's cuando el proyecto esté en operación completa, consolidando a Manzanillo como uno de los principales recintos portuarios de América Latina.

Los nuevos espacios portuarios se planean como plataformas de operación integradas, que incluyen patios de contenedores equipados con pavimentos de alta resistencia y sistemas de

almacenamiento, zonas de servicios logísticos, casetas aduanales, oficinas administrativas y áreas de inspección. En la configuración de ingeniería, se cuentan también espacios para equipos de manejo de carga pesada como grúas pórtico, reach stackers y vehículos eléctricos de traslado de contenedores. La coordinación entre la administración portuaria y operadores logísticos contempla la instalación de infraestructura digital para control y monitoreo de operaciones en tiempo real.

En materia de accesos terrestres, la ampliación incluye obras de conectividad vial y ferroviaria. Se planea infraestructura de carreteras de varios carriles que enlacen el nuevo puerto con la red nacional de carreteras, así como ramales ferroviarios dedicados que permitan el traslado eficiente de mercancías hacia y desde el centro del país y hacia frontera norte para su exportación o tránsito internacional. Aunque no se han difundido públicamente los metros lineales específicos, los proyectos referidos contemplan trenes prioritarios a la logística portuaria y carreteras de alta capacidad, incluyendo ampliaciones de autopistas existentes como la Colima–Manzanillo, con tramos de cuatro a seis carriles y vialidades estratégicas de integración con el recinto portuario.

La obra se concibe en dos etapas principales. La primera etapa abarca los dragados necesarios al canal de navegación, la preparación de terrenos mediante terracerías y rellenos hidráulicos, y la construcción de infraestructura básica —incluidas vialidades portuarias y accesos ferroviarios primarios— para permitir el establecimiento de las primeras terminales privadas. Esta fase también incluye la preparación de bases de cimentación para las estructuras pesadas y trabajos de mejoramiento de suelos. La segunda etapa se concentra en la construcción de terminales especializadas, infraestructura complementaria de servicios (agua potable, drenaje, electricidad, fibra óptica), estaciones de control aduanal, áreas administrativas y corredores de servicios integrados, las cuales estarán ubicadas donde actualmente se encuentran las islas Cocodrilo I y II.

La ingeniería portuaria también considera el manejo de sedimentos dragados. Dadas las características del Vaso II —sedimentos finos con alta materia orgánica y tiempos largos de residencia de agua—, será indispensable diseñar estrategias de disposición o reutilización de sedimentos que cumplan con la legislación ambiental, con análisis fisicoquímicos previos para evitar impactos en la calidad del agua y en los ecosistemas circundantes. Otra dimensión técnica está relacionada con la estabilidad de plataformas portuarias, las cuales requieren ingeniería geotécnica para prevenir asentamientos diferenciales, lo cual puede requerir el uso de mejoramientos de suelo como precarga, columnas de grava o drenes verticales.

El proyecto está programado para desarrollarse a lo largo de varios años, con inicio de obras preparatorias y dragado orientadas a completarse hacia mediados de la década, y con operaciones iniciales de terminales proyectadas para estar en servicio hacia 2029-2030, según los cronogramas de coordinadores portuarios.

En términos generales, la propuesta de ampliación del Puerto de Manzanillo en el Vaso II constituye un proyecto de reconversión funcional del espacio lagunar hacia un uso industrial-portuario de gran escala, con infraestructura marítima, terrestre y logística integrada, diseñado para incrementar la capacidad de manejo de carga y posicionar al puerto como un nodo estratégico de comercio internacional.

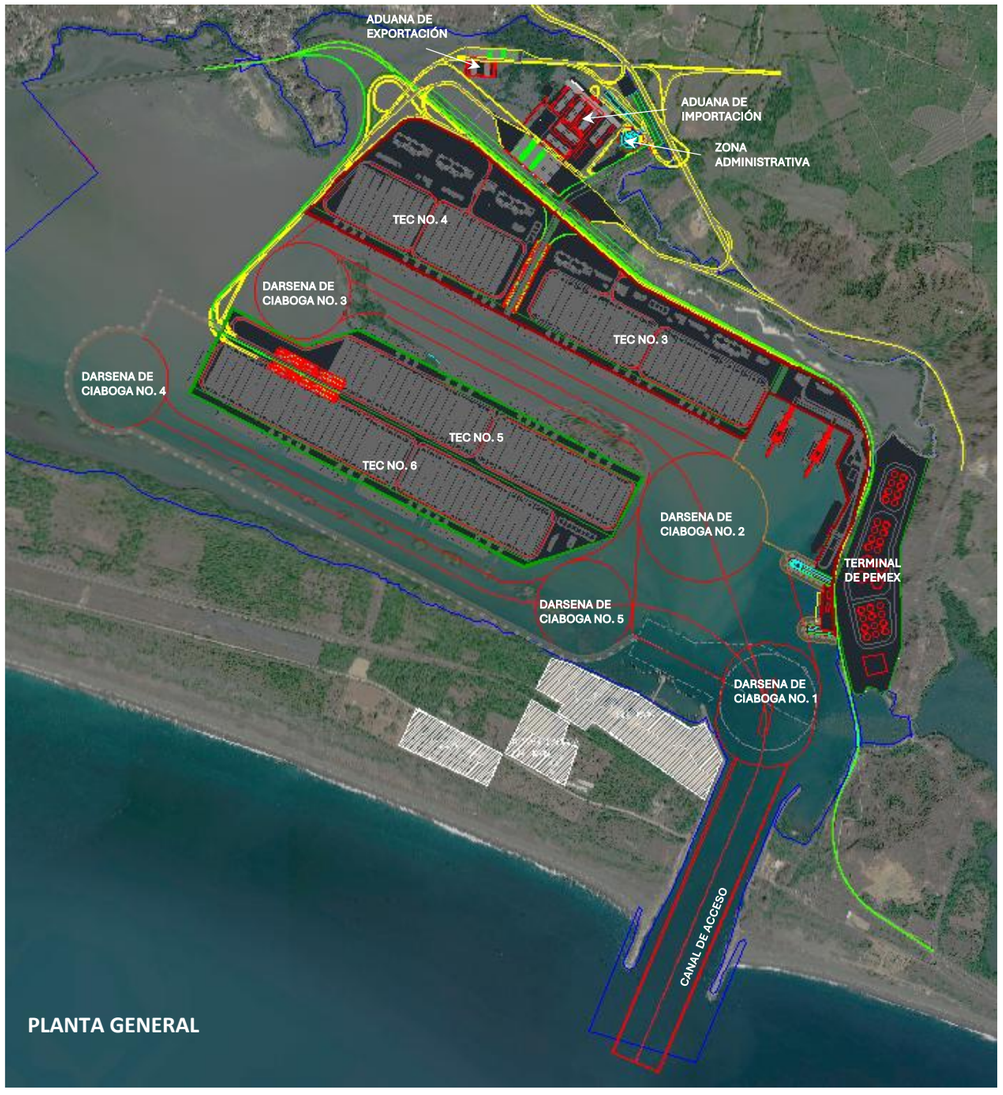
4.3.2 Diagnóstico Técnico de la Propuesta Original de la Ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán.

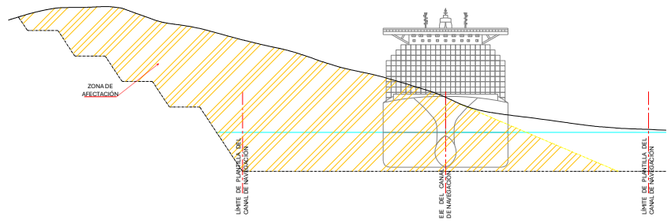
La información proporcionada por la ASIPONA Manzanillo, se presentan las áreas de navegación internas en la Laguna de Cuyutlán, ver Figura 4.10, las cuales se integran de las siguientes superficies:

12 26 60 01 16 20

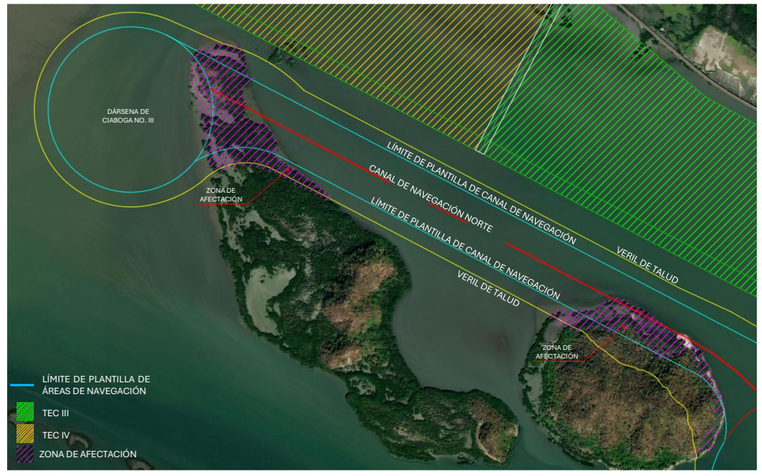
- Canal de acceso (CN-01):
  - Longitud: 1,988.60 m
  - Ancho: 300 m
  - Profundidad: -20.00 m
- Canal interior (CN-02):
  - Longitud: 4,341.82 m
  - Ancho: 200 m
  - Profundidad: -19.00 m
- Canal interior (CN-03):
  - Longitud: 4,391.26 m
  - Ancho: 200 m
  - Profundidad: -19.00 m
- Dársena de ciaboga No. 1I:
  - Longitud: 767 m
  - Ancho: 600 m
  - Profundidad: -19.00 m
- Dársena de ciaboga No. 2:
  - Diámetro: 800 m
  - Profundidad: -19.00 m
- Dársena de ciaboga No. 3:
  - Diámetro: 600 m
  - Profundidad: -19.00 m
- Dársena de ciaboga No. 4:
  - Diámetro: 600 m
  - Profundidad: -19.00 m
- Dársena de ciaboga No. 5:
  - Diámetro: 600 m
  - Profundidad: -19.00 m

Figura 4.10 Diagnóstico de Terminales e Infraestructura de la Alternativa Original de Desarrollo Portuario en la Laguna de Cuyutlán.





ISLA COCODRILO I – SECCIÓN DE CORTE



AFECTACIÓN DE MANGLE EN LA ZONA DE LAS ISLAS COCODRILO I Y II

Fuente: Elaboración propia con información obtenida del plano No. CA24-07-PC-PL-PDG-01 "*Plan Maestro y Dimensionamiento – General Plano General*", correspondiente a los "*Servicios de Ingeniería Marítima y Portuaria para la Actualización del Plan Maestro de Desarrollo de los Puertos de Manzanillo y de Laguna de Cuyutlán, Colima*", desarrollado por la empresa Aleph Ingenieros Consultores S.A. de C.V., 2025

En la primera etapa de desarrollo se contemplan dos terminales especializadas de contenedores (TEC). La TEC III tendrá una superficie de 95.55 Ha y un frente de atraque de 1,655 m, con la cual se tendrán tres posiciones de atraque. Mientras que para la TEC IV se ha destinado una superficie de 100.24 Ha y un frente de atraque de 1,380 m, también con tres posiciones de atraque.

De acuerdo con lo anterior, el área total de desarrollo para la primera etapa es de 225.51 ha, es importante comentar que esta superficie incluye la zona destinada a la terminal de PEMEX.

Para la segunda etapa de desarrollo se contemplan otras dos terminales especializadas de contenedores. La TEC V tendrá una superficie de 100.00 ha y un frente de atraque de 2,000 m, con la cual se tendrán cuatro posiciones de atraque. Mientras que para la TEC VI se ha destinado una superficie de 107.20 Ha y un frente de atraque de 2,700 m, con la cual se tendrán cinco posiciones de atraque. La superficie total de la segunda etapa es de 207.20 ha.

De la revisión técnica realizada a esta propuesta se han observado los siguientes puntos:

a. De acuerdo con el plano No. CA24-07-PC-PL-PDG-01 “Plan Maestro y Dimensionamiento – General Plano General”, correspondiente a los “Servicios de Ingeniería Marítima y Portuaria para la Actualización del Plan Maestro de Desarrollo de los Puertos de Manzanillo y de Laguna de Cuyutlán, Colima”[1], el canal de acceso cuenta con una longitud de 2,000 m, medidos desde el límite de la dársena de ciaboga existente (DC-01) hasta una longitud de 535.40 m fuera del limite de los morros de las escolleras.

   Esta longitud se indica como la longitud de parada de las embarcaciones que harán uso de la dársena DC-01, sin embargo, de acuerdo con las recomendaciones de diseño[2] la longitud de parada se mide desde la zona resguardada por las escolleras hasta el centro de la dársena de ciaboga.

b. Considerando lo anterior, la posición de la dársena de ciaboga DC-01, la cual se localiza al final del canal de acceso, su propuesta de diseño corresponde a que el buque de diseño realizará para total en ella, sin embargo, esta dársena se encuentra fuera de lugar, ya que, para que esta acción se realice es necesario recorrer la dársena hacia el norte aproximadamente 540 m.

[1] Desarrollado por la empresa Aleph Ingenieros Consultores S.A. de C.V., en el 2025

[2] Manual de Dimensionamiento Portuario, Dirección General de Puertos – CGP y MM – S.C.T., 1990
Nota: Distancia de parada (Dp). Como norma general la distancia de parada debe ser del orden de 5E, a partir de que la popa del barco alcanza la zona protegida por los rompeolas;

Asimismo, de acuerdo con los resultados observados en el estudio de passing[3] para el proyecto del muelle de combustibles de LFG en la Laguna de Cuyutlán, en la práctica los pilotos de puerto no realizan el paro total de la embarcación en la dársena del puerto (tal cual sucede hoy en día en el puerto de Manzanillo), sino que continúan con la maniobra de arribo y atraque de manera continua.

Por otra parte, los buques que realicen las maniobras de reviro en esta dársena serían los buquetanques de los muelles de combustibles de LFG y Porter, así como los buques de transporte de gas de KMS, siendo este último el que dio origen a la construcción de dicha dársena[4].

Considerando lo anterior, y con base que el desarrollo de la segunda etapa de desarrollo de la ampliación del puerto de Manzanillo en la Laguna de Cuyutlán será realizado a largo plazo, para la primera etapa no se ve la necesidad de modificar las dimensiones de dicha dársena.

c. La dársena de ciaboga DC-04 (en el plano no se indica DC-03), la cual se localiza al noroeste de la laguna, tiene un diámetro de 600 m, la cual es diferente a la dársena DC-02 cuyo diámetro es de 800 m, si se tiene en cuenta el buque de diseño cuya eslora es de 400 m, contemplando que las condiciones en el interior de la laguna son similares, es posible cuestionar que una de las dos dársenas tiene un planteamiento erróneo.

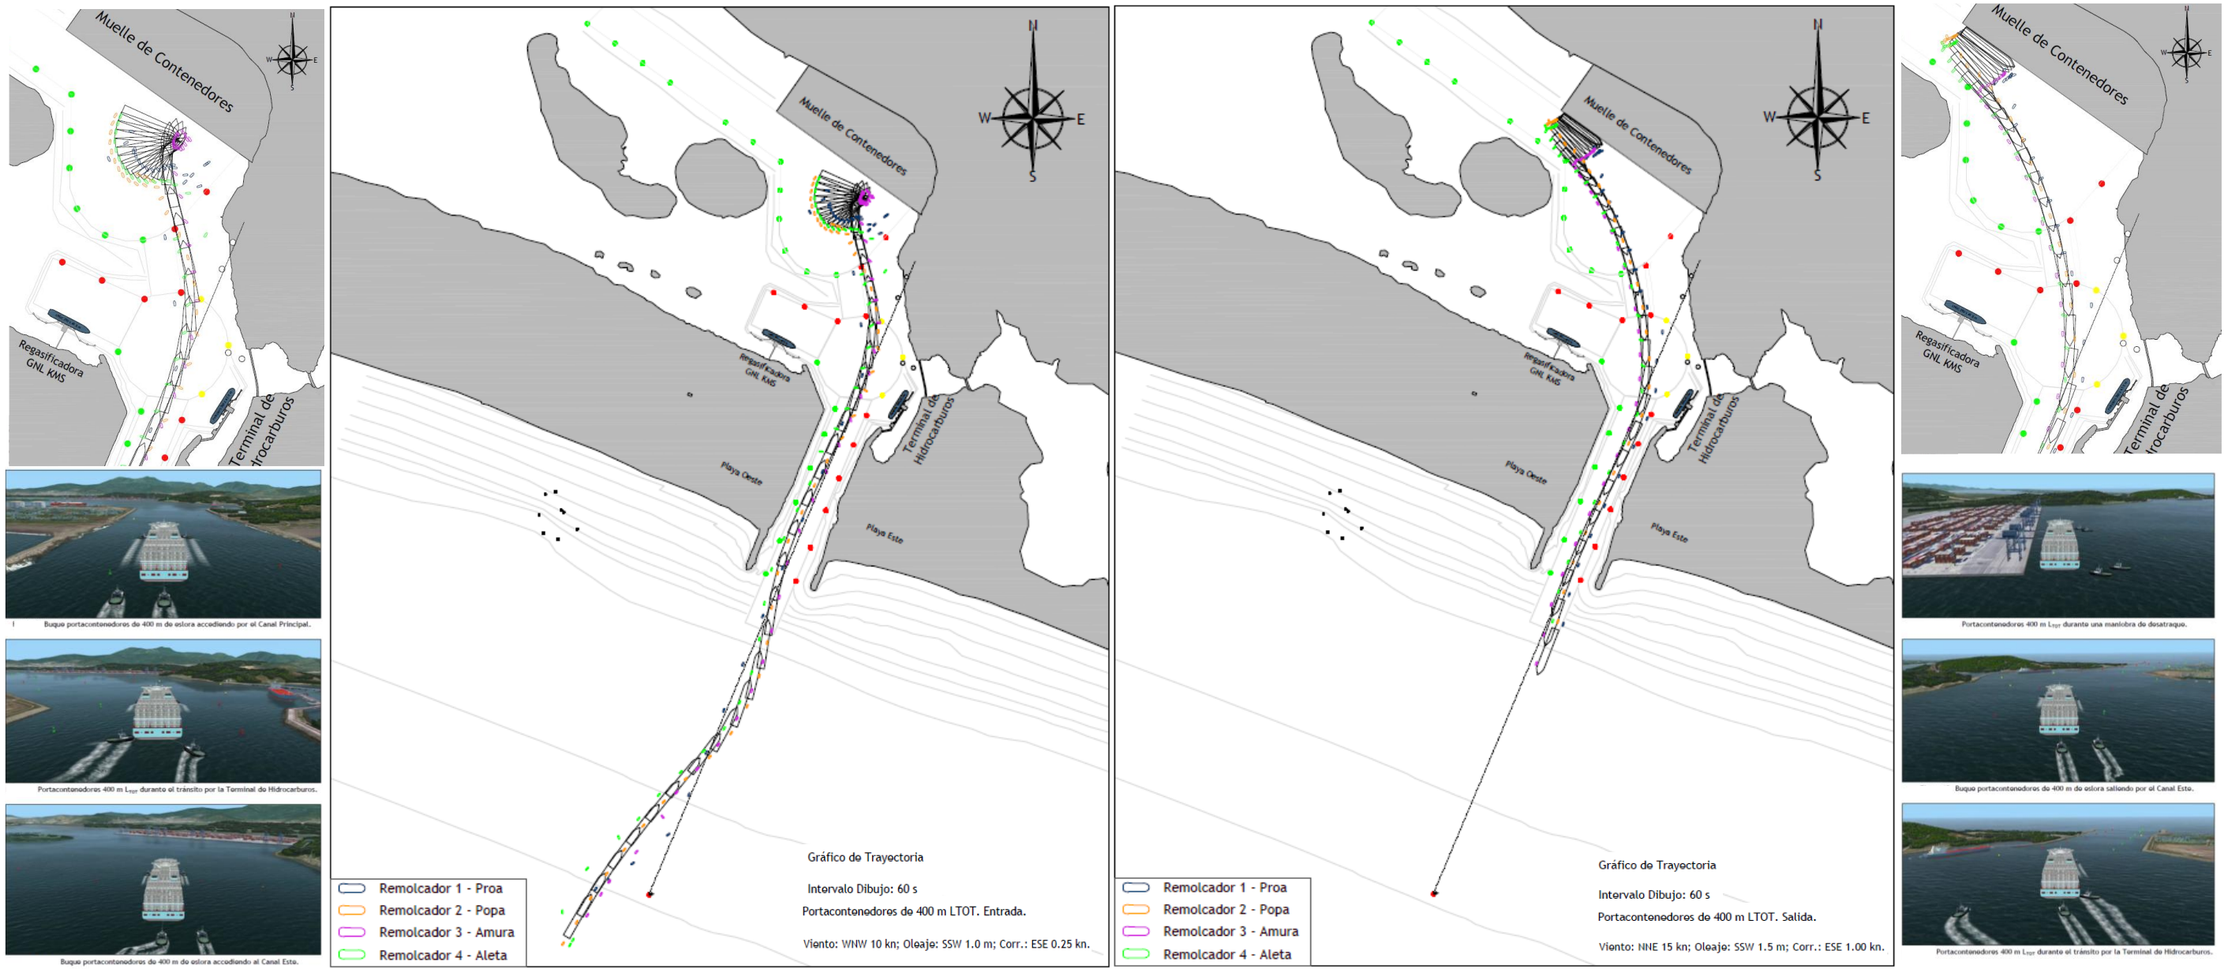
   Si bien para el dimensionamiento de la dársena de ciaboga las recomendaciones de diseño contemplan las características del buque de diseño, las condiciones de remolque, la maniobrabilidad del buque, señalización marítima y las condiciones físicas de la zona de proyecto, estas no tienen una variación importante para que las dársenas tengan dimensiones diferentes. Por otra parte, se debe considerar que la zona donde se localiza la dársena DC-04, en condiciones de marea baja la zona queda seca, el buque puede tener efectos de succión por las paredes que conforman la dársena.

   Considerando lo anterior, es recomendable mantener el diámetro de la dársena DC-04 en 800 m.

[3] Estudios Náuticos para la Ampliación Portuaria Proyectada en la Laguna de Cuyutlán Puerto de Manzanillo (Colima) Simulación de Maniobras en Tiempo Real, RHG Ingeniería, Enero del 2021,

[4] Buque metanero de 173,400 m3 (eslora=290 m, manga=45.8, calado a plena carga=11.95 m, calado en lastre=9.40 m, puntal=26.5 m, peso muerto a plena carga 90,000 TPM, desplazamiento a plena carga=120,400 t y un desplazamiento en lastre = 92,740 t.

Figura 4.11 Gráficas de Maniobras de Entrada y Salida Portacontenedores de 400 m de Eslora.



Fuente: Logística de Fluídos y Graneles S.A. De C.V., "*Estudio de Simulación de Maniobras en Tiempo Real para una Terminal de Hidrocarburos en el Puerto Laguna de Cuyutlán, Manzanillo (Colima)*", Noviembre 2019.

d. El planteamiento de las áreas interiores de navegación en la primera etapa, el dragado a -19 m en el canal de navegación CN-02, localizado entre la dársena de ciaboga DC-02 y la dársena DC-04, tiene una afectación importante sobre la isla cocodrilo No. I. Dicha isla tiene una superficie en planta de 28.90 Ha, de las cuales con los trabajos de dragado se afectará una superficie aproximada de 9.56 Ha (lo que representa un 33% del total).

   En la segunda etapa de desarrollo, la afectación se extiende al 100% de la superficie de ambas islas.

   Un punto importante para considerar en la planeación del desarrollo portuario es que ambas islas están conformadas por granito y, tan solo, la isla cocodrilo I tiene una altura de 86 m sobre el nivel de bajamar media inferior (NBMI). Lo cual implica un retiro importante de roca y costos elevados para realizar tal tarea.

e. La afectación de la isla cocodrilo no solo se centra en la modificación del cuerpo de la isla, sino también tiene una afectación desde el punto de vista ambiental. Con el trazo planteado de las áreas de navegación tiene una afectación directa sobre las zonas de mangle, ver Figura 6.3, el total del área afectada de manglar es de 16.45 Ha. En el caso de la isla cocodrilo No. I, la zona de mangle que es afectada es aproximadamente de 6.10 Ha (lo que representa el 33% del total del área), y en el caso de la isla cocodrilo No. II, es de 10.35 Ha (lo que representa el restante 67% del total del área).

f. El canal de acceso actualmente tiene un ancho entre escolleras de 500 m en una longitud de 300 m, posteriormente el canal de acceso se reduce a 400 m. El ancho de platilla es de 250 m y una profundidad de -15 m (referidos al NBMI).

   En la propuesta de ampliación se tiene contemplado ampliar el canal de acceso a 300 m de ancho. Sin embargo, no se presentan los análisis de estabilidad de los taludes para revisar si se presenta alguna afectación en las obras de protección en ambas márgenes del canal de acceso o en su defecto la propuesta de estructuración para la estabilización de dichas márgenes y evitar algún daño a la infraestructura existente.

g. En la segunda etapa se presentan las dársenas de ciaboga DC-05 y DC-06, se presentan con un diámetro de 600 m, que es el mismo caso de la dársena DC-04, es necesario revisar el dimensionamiento de ambas dársenas.

   Por otra parte, la ubicación de la dársena DC-05, dada la cercanía de la dársena DC-02 y de las áreas comunes de agua en la zona, es necesario revisar su ubicación y utilidad mediante un estudio de maniobrabilidad.

Figura 4.12 Canal de Acceso en la Laguna de Cuyutlán.

Fuente: Elaboración propia, 2026.

h. La zona propuesta para el desarrollo de las terminales de la segunda etapa tiene una superficie total de 207.20 ha y con esta extensión se ven afectadas ambas islas cocodrilo en el 100% de su extensión, principal situación observada por la SEMARNAT.

i. En la zona propuesta para la localización de la zona de aduanas y zona administrativa se localiza una superficie importante de manglar que se verá afectada. La superficie total de afectación del manglar derivado de la propuesta de ampliación es aproximadamente de 90 ha.

En resumen, si bien se tienen observaciones en el ámbito técnico, estas se pueden solventar en la nueva propuesta de desarrollo. Asimismo, existen aspectos ambientales que deben ser atendidos, el principal de ellos es que en el área del proyecto se presenta vegetación de manglar, este es uno de los puntos jurídicamente más relevantes, ya que impone restricciones estrictas sobre afectación, remoción y alteración del manglar.

4.3.3 Restricciones Ambientales, Sociales e Infraestructurales en el Vaso II.

La ampliación del Puerto de Manzanillo hacia la Laguna de Cuyutlán constituye un proyecto de infraestructura portuaria de gran escala cuyo objetivo principal es incrementar la capacidad operativa del puerto más importante del Pacífico mexicano. La propuesta contempla la habilitación del denominado Nuevo Puerto Manzanillo-Cuyutlán dentro del Vaso II del sistema lagunar, mediante la construcción de infraestructura marítima y terrestre que permita el arribo y operación de buques de mayor calado y capacidad de carga, particularmente en el manejo de contenedores.

4.3.3.1 Aspectos técnicos.

Desde el punto de vista técnico, el proyecto implica la modificación sustancial del medio físico lagunar mediante dragado de canales de navegación, conformación de dársenas, construcción de muelles, rellenos hidráulicos para la creación de plataformas logísticas y la instalación de infraestructura complementaria como patios de almacenamiento, vialidades internas, accesos carreteros y posibles conexiones ferroviarias. Estas obras requieren la remoción y redistribución de grandes volúmenes de sedimento, alterando la configuración del fondo lacustre original del Vaso II, modificando gradientes de profundidad y potencialmente alterando los patrones de circulación interna del agua.

4.3.3.2 Aspectos Ambientales.

El Vaso II es un cuerpo lagunar somero caracterizado por elevada evaporación estacional, limitada renovación hídrica y alta variabilidad de salinidad. Su dinámica depende del intercambio con otros vasos del sistema y de procesos naturales de mezcla y evaporación. La introducción de infraestructura rígida y el dragado permanente para mantener calados operativos generan cambios en el régimen hidrodinámico, que pueden modificar tiempos de residencia del agua, patrones de sedimentación y procesos de dispersión de nutrientes y contaminantes.

4.3.3.3 Manglar

Desde la perspectiva ambiental, el Vaso II forma parte de un sistema lagunar que alberga comunidades de manglar fragmentadas pero funcionales, vegetación halófita, comunidades bentónicas adaptadas a sedimentos finos y una importante avifauna asociada a planicies someras. La transformación de áreas someras en zonas de mayor profundidad altera hábitats críticos para organismos bentónicos y aves playeras, además de modificar zonas de crianza para peces y crustáceos juveniles. Asimismo, el dragado y relleno implican la remoción de sedimentos con

posibles concentraciones de materia orgánica acumulada, cuya resuspensión puede generar episodios de turbidez elevada y disminución de oxígeno disuelto.

El manglar dentro del sistema lagunar actúa como un regulador natural de la dinámica costera y lagunar. Desde el punto de vista físico, sus raíces aéreas y estructuras radiculares complejas disminuyen la energía del oleaje, favorecen la sedimentación fina y estabilizan los bordes lagunares. En el Vaso II, donde la profundidad natural es reducida y la evaporación estacional genera incrementos de salinidad, el manglar funciona como amortiguador ecológico frente a fluctuaciones extremas, ayudando a mantener microambientes con condiciones relativamente más estables.

En términos de dinámica salina, el manglar requiere un régimen periódico de inundación con salinidades dentro de rangos fisiológicamente tolerables. La profundización del vaso y la creación de canales permanentes de mayor intercambio pueden modificar gradientes de salinidad natural. Si aumenta la influencia marina directa o se generan zonas de estancamiento por barreras artificiales, podrían presentarse cambios en la concentración salina que excedan la tolerancia de especies menos resistentes, generando estrés fisiológico y mortalidad localizada. En el Vaso II, donde ya existe tendencia a hipersalinidad por evaporación, la alteración de circulación puede amplificar condiciones extremas.

La vulnerabilidad del manglar del Vaso II es alta debido a su fragmentación y limitada extensión. Cualquier alteración adicional en régimen hídrico puede reducir su resiliencia. Las islas centrales, aunque no siempre densamente vegetadas, cumplen función estructural que protege indirectamente al manglar. La pérdida de estas estructuras naturales podría traducirse en simplificación del paisaje lagunar y reducción de servicios ecosistémicos.

4.3.3.4 Islas Cocodrilo I y II

La planeación propuesta contempla el retiro de las dos islas cocodrilo, estas islas centrales de la laguna, muchas de ellas compuestas por acumulaciones sedimentarias naturales y en algunos casos con cobertura vegetal halófita o fragmentos de manglar, cumplen funciones geomorfológicas clave. Actúan como barreras naturales que modifican corrientes internas, generan zonas de sombra hidrodinámica y crean gradientes de energía que permiten la deposición de sedimentos finos. Estas islas influyen directamente en la distribución espacial de los bentos, en la formación de planicies someras utilizadas por aves playeras y en la configuración de zonas de crianza para peces y crustáceos.

La ampliación del puerto implica dragados de profundización, rectificación de canales y potencial modificación o remoción de islotes centrales para permitir la configuración geométrica requerida por las dársenas de maniobra y los muelles. La eliminación o alteración parcial de estas islas tendría consecuencias directas en la redistribución de flujos internos dentro del Vaso II. Al modificarse las barreras naturales que actualmente atenúan corrientes y oleaje, podría

incrementarse la energía hidrodinámica en sectores previamente protegidos, alterando patrones de sedimentación y favoreciendo erosión en bordes lagunares donde se ubica el manglar.

Desde el punto de vista ecológico, la interacción entre manglar e islas centrales configura una red de microhábitats interdependientes. Las raíces del manglar sirven como sustrato para invertebrados, refugio para juveniles de peces y áreas de alimentación para aves. Las islas centrales, al mantener planicies de baja profundidad alrededor, permiten la formación de hábitats idóneos para aves migratorias que dependen de zonas de alimentación someras. La alteración de la geomorfología interna del vaso puede modificar la distribución de profundidades, eliminando áreas de transición entre agua profunda y planicie somera, con pérdida de hábitats funcionales.

Adicionalmente, las islas centrales pueden contener valor patrimonial y cultural, además de su función ecológica. Su remoción no sólo implica transformación física sino también pérdida de referencias territoriales históricas y posibles sitios arqueológicos. Desde una perspectiva socioambiental, esta dimensión añade complejidad al proyecto, pues vincula infraestructura portuaria con patrimonio natural y cultural.

En síntesis, el manglar y las islas centrales del Vaso II no son elementos aislados, sino componentes integrados en la dinámica ecológica y geomorfológica del sistema lagunar. La ampliación del Puerto de Manzanillo representa una intervención que modifica de manera directa la morfología y circulación interna del vaso, por lo que su compatibilidad con la conservación de estos elementos depende de la capacidad del proyecto para mantener conectividad hidrológica, estabilidad sedimentaria y condiciones salinas dentro de rangos ecológicamente tolerables.

4.3.3.5 Ámbito Social.

En el ámbito social, el área de influencia del proyecto mantiene actividades productivas tradicionales como pesca artesanal y salinas históricas. La alteración del Vaso II puede incidir directamente en la disponibilidad de recursos pesqueros y en la funcionalidad de áreas de extracción de sal, generando impactos socioeconómicos acumulativos. Además, se han señalado valores culturales y patrimoniales asociados a islotes y espacios dentro de la laguna, lo que añade una dimensión patrimonial a la evaluación del proyecto.

En este contexto, el análisis comparativo entre el proyecto de ampliación y las restricciones existentes en el Vaso II evidencia una tensión estructural entre la lógica de expansión portuaria y la vocación ecológica y social del territorio. El sistema lagunar presenta restricciones ambientales vinculadas a la conservación de humedales, mantenimiento de conectividad hidrológica, protección de manglares y cumplimiento de marcos normativos en materia de impacto ambiental y ordenamiento ecológico. Desde la dimensión social, existen restricciones derivadas del derecho de las comunidades a mantener sus medios de vida, así como de la obligación de realizar procesos de consulta pública efectivos.

4.3.3.6 Restricciones de Infraestructura

A estas restricciones ambientales y sociales se suman restricciones estrictamente técnicas e infraestructura-les que deben ser consideradas para la viabilidad del proyecto. El Vaso II presenta limitaciones geomorfológicas derivadas de su escasa profundidad natural, lo que implica que el mantenimiento de canales de navegación requerirá dragado periódico permanente. Este dragado continuo no solo representa un costo operativo elevado, sino que genera un problema técnico recurrente de disposición de sedimentos, cuya gestión debe cumplir con normativas ambientales y evitar la afectación de áreas ecológicamente sensibles. Asimismo, la naturaleza limosa del fondo lagunar puede generar inestabilidad geotécnica para la cimentación de estructuras pesadas, lo que obliga a realizar estudios detallados de mecánica de suelos, consolidación y capacidad portante, así como posibles tratamientos de mejoramiento del terreno.

Otro aspecto crítico es la interacción entre infraestructura portuaria y régimen hidrológico. La construcción de plataformas y muelles puede actuar como barrera física que altere corrientes internas y genere zonas de estancamiento, lo cual incrementa el riesgo de eutrofización localizada y deterioro de calidad del agua. Además, la operación portuaria incrementa el tráfico marítimo dentro de un cuerpo de agua originalmente no diseñado para navegación intensiva de gran calado, lo que implica riesgos asociados a derrames, descargas accidentales y alteraciones de dinámica sedimentaria por oleaje inducido por embarcaciones.

En términos de infraestructura externa, la ampliación requiere adecuaciones viales y ferroviarias que pueden generar impactos adicionales fuera del vaso lagunar, incluyendo fragmentación de hábitat terrestre y aumento de presión urbana. La compatibilidad de esta infraestructura con los instrumentos de ordenamiento territorial vigentes constituye otra restricción relevante.

Ante este panorama, el proyecto demanda el desarrollo de estudios técnicos avanzados que permitan evaluar de manera integral su viabilidad. Resulta indispensable la elaboración de modelos hidrodinámicos que simulen escenarios con y sin proyecto, evaluando cambios en circulación, tiempos de residencia y dispersión de contaminantes. Es necesario desarrollar estudios de transporte de sedimentos que permitan estimar tasas de colmatación y frecuencia óptima de dragado, así como análisis de calidad de sedimentos para determinar riesgos asociados a su disposición.

Asimismo, se requiere una caracterización ecológica de línea base de alta resolución que incluya inventarios de flora y fauna, análisis de comunidades bentónicas y evaluación detallada de cobertura y estado del manglar en el Vaso II. Estudios de dinámica salina estacional permitirán identificar umbrales críticos de tolerancia para especies clave. Desde la dimensión social, deben realizarse evaluaciones de impacto socioeconómico que cuantifiquen afectaciones potenciales a pesca y salinas, así como procesos participativos formales que documenten la percepción comunitaria y las medidas de compensación necesarias.

Complementariamente, se deben desarrollar proyectos específicos de mitigación y restauración, tales como programas de restauración de manglar en áreas degradadas, diseño de corredores hidrológicos que mantengan conectividad, sistemas de monitoreo permanente de calidad de agua y biodiversidad, y planes de manejo de sedimentos dragados que minimicen impactos secundarios.

En conclusión, la ampliación del Puerto de Manzanillo en el Vaso II de la Laguna de Cuyutlán constituye una intervención de alta complejidad técnica que enfrenta restricciones ambientales, sociales e infraestructura-les significativas. La viabilidad del proyecto depende no solo de su ingeniería portuaria, sino de la capacidad de integrar estudios científicos robustos, planificación adaptativa y procesos de gobernanza ambiental que permitan armonizar el desarrollo logístico con la conservación ecológica y el bienestar social del sistema lagunar.

4.3.4 Diagnóstico y Pronóstico de Interacción entre Manglar, Islas Centrales de la Laguna de Cuyutlán y la Ampliación del Puerto de Manzanillo en el Vaso II

4.3.4.1 Diagnóstico de base ambiental y funcional

La Laguna de Cuyutlán es un sistema lagunar costero cuya estabilidad depende de la interacción entre su morfología somera, su conectividad interna por vasos, los procesos de evaporación–renovación, y la dinámica de sedimentos finos. Dentro de ese marco, el manglar y los islotes centrales funcionan como componentes estructurales que regulan la energía hidrodinámica, controlan rutas de transporte y depósito de sedimentos y sostienen mosaicos de hábitat somero indispensables para cadenas tróficas estuarinas. La evidencia técnica de caracterización de manglar para Cuyutlán reconoce presiones históricas asociadas a dragados en la laguna y a la modificación de corrientes por apertura de canales de comunicación con el mar, además de otros factores de perturbación que han incidido en la integridad del humedal.

En condiciones actuales, el manglar del sistema —incluidos parches fragmentados asociados al Vaso II— aporta estabilización ribereña, retención de sedimentos finos y amortiguamiento frente a oleaje y corrientes internas. Los islotes centrales, por su parte, actúan como “obras naturales” que generan zonas de sombra hidrodinámica y propician la deposición diferenciada de sedimento, manteniendo planicies someras y gradientes de profundidad que son determinantes para el bentos y para la disponibilidad de alimento de aves acuáticas. La relevancia socioecológica del sistema, con biodiversidad notable y vínculos con pesca y salinas tradicionales, ha sido ampliamente destacada en el debate público reciente sobre la expansión portuaria.

4.3.4.2 Descripción del forzamiento físico del proyecto sobre el Vaso II

El proyecto de ampliación portuaria hacia el Vaso II, referido públicamente como Nuevo Puerto Manzanillo–Cuyutlán, se ha descrito como una intervención de gran escala con nuevas

terminales especializadas y reconfiguración del vaso mediante obras típicas de ingeniería portuaria, incluyendo dragados, conformación de áreas operativas y muelles. Desde la comunicación oficial del gobierno federal se ha señalado un paquete de terminales que incluye, al menos, una terminal de contenedores y terminales para graneles y para hidrocarburos, con metas de capacidad relevantes para el desempeño logístico del puerto. De manera complementaria, también se ha difundido que el esquema de desarrollo considera terminales privadas, reportándose parámetros de referencia como terminales del orden de 100 hectáreas por terminal y alrededor de 1,500 metros de muelle por unidad en ciertos planteamientos iniciales, lo que sugiere una huella marítimo-terrestre considerable en el vaso.

Independientemente del desglose final de terminales, el elemento común es que, para lograr condiciones operativas portuarias dentro de un cuerpo lagunar somero, el proyecto necesariamente introduce un forzamiento físico dominante: profundiza y estabiliza un sistema que naturalmente tiende a la colmatación y a la variabilidad salina, aumenta el tránsito de embarcaciones en aguas interiores y agrega estructuras rígidas (muelles, bordos, tablestacados, plataformas) que alteran el campo de corrientes, la disipación de energía y el balance sedimentario.

4.3.4.3 Interacción proyecto–manglar: mecanismos de impacto y umbrales críticos

El manglar es particularmente sensible a cambios en el régimen de inundación, en la salinidad y en la oxigenación del sedimento. En el Vaso II, donde la evaporación estacional puede concentrar sales y el tiempo de residencia del agua tiende a ser alto, pequeñas modificaciones de conectividad interna o del patrón de circulación pueden traducirse en cambios persistentes de salinidad y en episodios prolongados de baja oxigenación del fondo. Si el diseño portuario incrementa el intercambio con agua marina profunda en determinadas trayectorias, puede desplazar gradientes salinos y modificar la frecuencia de inundación efectiva en bordes; si, por el contrario, crea compartimentaciones o zonas de estancamiento detrás de estructuras, puede incrementar la permanencia de agua con altas temperaturas y favorecer condiciones eutróficas o hipóxicas en proximidad del manglar. En ambos casos, el resultado técnico esperado no es solo una respuesta biológica, sino un cambio en el desempeño del manglar como estabilizador de borde: bajo estrés crónico, disminuye la regeneración, se incrementa la mortalidad localizada y se amplifican los efectos de borde, lo que hace más probable el retroceso de la línea vegetada.

A este mecanismo se añade el efecto físico-mecánico asociado a navegación intensiva y operaciones portuarias en aguas interiores. El oleaje inducido por buques, las corrientes de hélice y las reflexiones contra estructuras rígidas pueden incrementar la socavación en márgenes, afectando directamente las raíces y neumatóforos del manglar. En un sistema fragmentado, la pérdida de continuidad del manglar no ocurre de forma homogénea; tiende a iniciar en puntos débiles y luego acelera por retroalimentación, porque cada brecha incrementa la exposición hidráulica del parche remanente.

4.3.4.4 Interacción proyecto–islotes centrales: morfodinámica, sedimentos y función ecológica

Los islotes centrales de la laguna cumplen una función morfodinámica que resulta crítica en vasos someros: atenúan corrientes, inducen deposición en sotavento, y sostienen planicies someras adyacentes que actúan como hábitat para invertebrados y como áreas de alimentación para aves. Cuando un proyecto portuario requiere habilitar canales de navegación, dársenas o polígonos de plataformas, los islotes tienden a considerarse obstáculos geométricos que pueden ser removidos, recortados o aislados. La pérdida o modificación de islotes no solo implica la eliminación de superficie emergente, sino que reordena el campo de corrientes y el transporte de sedimentos, generando un nuevo equilibrio morfológico en el que el sistema intenta redistribuir material fino hacia zonas de menor energía. En términos operativos, esto suele traducirse en mayor necesidad de dragado de mantenimiento por colmatación acelerada en rutas preferentes, y en términos ambientales, puede provocar erosión de bordes previamente protegidos, incluidos bordes con manglar.

Este punto tiene además una dimensión social y patrimonial: se ha señalado públicamente que la ampliación requeriría la remoción de islotes con valor arqueológico y ecológico, lo cual intensifica restricciones no solo ambientales, sino también culturales y de aceptación social del proyecto.

4.3.4.5 Evaluación diagnóstica integrada: por qué el Vaso II es un punto de conflicto técnico.

La integración de mecanismos anteriores indica que el Vaso II opera hoy como un sistema de equilibrio delicado donde la geomorfología somera, el manglar ribereño y los islotes centrales sostienen funciones de control físico y ecológico. La ampliación portuaria introduce un régimen alternativo dominado por dragados, estructuras rígidas y navegación intensiva. En esa transición, el riesgo técnico principal es el cambio de régimen del sistema: pasar de un humedal somero regulado por barreras naturales a un vaso interior semi-industrial con profundidades artificiales y flujo controlado. En ese tipo de transiciones, los impactos tienden a ser no lineales: existe un punto a partir del cual la pérdida de control natural del sedimento y la alteración de corrientes dejan de ser mitigables con medidas menores y requieren intervenciones permanentes (dragados crecientes, defensas marginales, confinamientos), elevando costos y ampliando huella ambiental.

Restricción regulatoria y social: condición actual del proyecto como elemento del pronóstico

En el pronóstico realista, la principal restricción inmediata es regulatoria: Semarnat frenó el proyecto en el Vaso II al considerar que provocaría impactos ambientales no evaluados y riesgos potencialmente irreversibles, señalando que el planteamiento rebasaba el estudio presentado. En paralelo, se han documentado posicionamientos de organizaciones y comunidades que vinculan la

expansión con afectaciones a ecosistemas, medios de vida tradicionales y valores culturales del humedal. Estas condiciones inciden directamente en el pronóstico porque implican que, aun si el proyecto se mantiene como objetivo, su ingeniería deberá re-plantearse y justificarse con mayor robustez técnica y social para ser viable.

4.3.4.6 Pronóstico con proyecto: escenarios de cambio esperable sobre manglar e islotes

Bajo un escenario con proyecto en configuración similar a la reportada públicamente, el pronóstico técnico sobre el manglar del Vaso II es de aumento significativo de vulnerabilidad por tres vías: incremento de estrés salino e hidrológico por reordenamiento de circulación; aumento de presión mecánica sobre bordes por oleaje inducido y reflexiones; y reducción de resiliencia por fragmentación adicional o pérdida de conectividad ecológica. En cuanto a islotes, el pronóstico más probable es que su remoción o aislamiento provoque redistribución de sedimentos y un reacomodo morfológico que tienda a colmatar zonas dragadas y a erosionar márgenes expuestos, incrementando tanto el mantenimiento requerido como la presión sobre hábitats someros.

Bajo un escenario sin proyecto o con intervención mínima, el pronóstico es distinto: se mantiene la arquitectura de control natural, pero persisten presiones históricas ya identificadas (dragados previos, modificaciones de corrientes, contaminación), lo que sugiere una trayectoria de degradación más gradual y localizada, con oportunidades de restauración y manejo adaptativo.

4.3.4.7 Estudios mínimos indispensables y proyectos técnicos por desarrollar para decidir viabilidad

Para que el proyecto pueda compararse contra restricciones ambientales y sociales del Vaso II con rigor suficiente, es indispensable un paquete de estudios que no solo describa obras, sino que demuestre comportamiento del sistema “con” y “sin” proyecto. El primer estudio crítico es una modelación hidrodinámica tridimensional calibrada con mediciones de campo estacionales, capaz de simular circulación, estratificación, tiempos de residencia y dispersión de trazadores bajo geometría actual y bajo geometría proyectada. Sin esta modelación, cualquier afirmación sobre estabilidad de salinidad, calidad de agua o preservación de condiciones para manglar sería especulativa.

El segundo estudio crítico es una modelación morfodinámica y de transporte de sedimentos que estime tasas de erosión-deposición, colmatación esperada y frecuencia de dragado de mantenimiento, incorporando explícitamente el papel de islotes actuales y el cambio de régimen al removerlos o modificarlos. Este componente debe integrar caracterización granulométrica y geoquímica de sedimentos, porque la disposición o reutilización del material dragado en sistemas lagunares con sedimentos finos y materia orgánica requiere demostrar que no se inducirán deterioros crónicos de turbidez y oxigenación.

El tercer bloque indispensable es un diagnóstico ecológico de alta resolución centrado en manglar y hábitat somero del Vaso II, que incluya estructura, regeneración, condición sanitaria, conectividad entre parches y sensibilidad a salinidad, además de una línea base robusta de bentos y de uso de hábitat por avifauna asociada a planicies someras. Este diagnóstico debe traducirse en umbrales operativos: rangos de salinidad, turbidez y oxígeno disuelto compatibles con persistencia del manglar y con la base trófica del sistema.

El cuarto bloque es un estudio de ingeniería de protección de márgenes y control de oleaje inducido por navegación, que evalúe alternativas de diseño para minimizar socavación en bordes con manglar, incluyendo configuración de dársenas, velocidades permitidas, diseño de defensas y disipadores, y criterios de operación marítima en aguas interiores.

El quinto bloque es el estudio patrimonial y arqueológico específico para islotes y áreas de relleno o dragado, con metodología de prospección y medidas de evitación, rescate o rediseño, dado que la remoción de islotes ha sido señalada como un punto de conflicto por su posible valor cultural además del ecológico.

Finalmente, para atender la restricción social, es indispensable un estudio socioambiental con enfoque de medios de vida, que cuantifique dependencia local de la laguna (pesca, salinas, servicios ecosistémicos), identifique impactos acumulativos y defina medidas de manejo y compensación verificables, acompañado de un proceso de participación pública que sea trazable y técnicamente vinculante, en congruencia con el nivel de controversia documentado.

4.3.4.8 Cierre técnico

En conjunto, el diagnóstico indica que manglar e islotes centrales en el Vaso II no son elementos “accesorios” del paisaje, sino componentes que sostienen el control físico del sistema (sedimentos, energía interna, gradientes de profundidad) y, por extensión, su funcionalidad ecológica y social. El pronóstico con ampliación, si no se rediseña con base en evidencia modelada y umbrales ecológicos, apunta a una transición de régimen con pérdida de hábitat somero, incremento de mantenimiento por colmatación y aumento de vulnerabilidad del manglar. La existencia de un freno regulatorio reciente confirma que, en el estado actual de información, el proyecto no ha acreditado la suficiencia técnica de su evaluación para este entorno.

4.4 Criterios Técnicos para el Adecuado Dimensionamiento de la Ampliación Portuaria en el Vaso II de la Laguna de Cuyutlán

El dimensionamiento de una ampliación portuaria dentro de un sistema lagunar somero como el Vaso II no puede definirse únicamente por proyecciones de demanda logística o capacidad de manejo de carga. Debe establecerse bajo un enfoque de capacidad ambiental condicionante, en el cual la ingeniería portuaria se subordine a los límites físicos, ecológicos y sociales del sistema receptor. En este sentido, el dimensionamiento adecuado requiere cumplir

criterios integrados de hidrodinámica, morfodinámica, calidad ambiental, estabilidad ecológica, seguridad operativa y viabilidad social.

a. Criterio hidrodinámico: mantenimiento del régimen natural de circulación.

El primer condicionante técnico es que la ampliación no altere de forma crítica el régimen de circulación interna del Vaso II ni incremente significativamente el tiempo de residencia del agua. En sistemas lagunares someros, el equilibrio entre renovación hídrica, evaporación y mezcla vertical determina la estabilidad salina y el oxígeno disuelto. La modificación geométrica del vaso mediante dragados profundos y plataformas rígidas puede inducir cambios no lineales en estos procesos.

El dimensionamiento debe demostrarse mediante modelación hidrodinámica tridimensional calibrada con datos de campo estacionales. Esta modelación debe comparar escenarios sin proyecto y con proyecto, evaluando variaciones en velocidades de corriente, patrones de recirculación, estratificación salina y tiempos de residencia.

El indicador clave será la variación porcentual del tiempo de residencia promedio respecto al estado base. Como criterio precautorio, el incremento no debería superar valores que induzcan riesgo de eutrofización o hipersalinidad persistente en bordes con manglar. Asimismo, deberán establecerse umbrales operativos de salinidad y oxígeno disuelto compatibles con la permanencia del manglar y de los bentos.

b. Criterio morfodinámico: estabilidad sedimentaria y sostenibilidad del dragado.

El segundo criterio establece que el proyecto no debe inducir un régimen de colmatación[5] acelerada que obligue a dragados de mantenimiento crecientes e insostenibles. La eliminación o modificación de islotes centrales puede alterar rutas naturales de transporte de sedimentos y provocar erosión en márgenes o acumulación en canales.

El dimensionamiento del canal, dársenas y áreas operativas debe sustentarse en modelación de transporte de sedimentos y balance morfodinámico. Deben estimarse tasas anuales de sedimentación esperadas y frecuencia óptima de dragado de mantenimiento bajo diferentes escenarios hidrológicos.

[5] La colmatación es el proceso de relleno o acumulación de sedimentos (lodos, arena, arcilla) en los intersticios de un medio poroso, fondo de ríos, lagos o embalses, provocado por el agua o el viento. Este fenómeno disminuye drásticamente la permeabilidad del suelo y reduce la capacidad de almacenamiento de agua en infraestructuras. Asimismo, Provoca la pérdida de profundidad en lagunas y embalses, convirtiéndolos en zonas de barrizales. Reduce el oxígeno en el agua y altera los hábitats acuáticos.

El indicador clave será la tasa proyectada de colmatación anual y el volumen de dragado de mantenimiento requerido. Un diseño adecuado deberá demostrar estabilidad relativa del canal sin incrementos exponenciales de dragado y sin generación de erosión en zonas de manglar o planicies someras.

c. Criterio ecológico: preservación de manglar y hábitat somero funcional.

El manglar en el Vaso II presenta fragmentación y alta vulnerabilidad. El dimensionamiento del puerto debe evitar afectación directa, reducción adicional de conectividad o alteración significativa del régimen de inundación que comprometa su regeneración.

La demostración técnica requiere un diagnóstico ecológico de línea base de alta resolución que incluya estructura, densidad, regeneración, condición sanitaria y conectividad de parches de manglar, así como caracterización de bentos y uso de hábitat por avifauna.

Los indicadores incluyen cobertura de manglar, tasa de regeneración natural, diversidad bentónica y estabilidad de planicies someras. El umbral operativo debe ser la no disminución neta de cobertura funcional ni reducción significativa de diversidad asociada.

d. Criterio de calidad de agua: control de turbidez, nutrientes y oxígeno.

El dragado y la operación portuaria incrementan turbidez y riesgo de resuspensión de sedimentos finos con alta materia orgánica. El dimensionamiento debe incluir estrategias de control de turbidez durante construcción y definir límites operativos en fase de operación.

El proyecto deberá establecer un programa de monitoreo continuo de turbidez, nitrógeno total, fósforo total y oxígeno disuelto, con valores gatillo que obliguen a detener o ajustar operaciones si se rebasan umbrales ecológicamente críticos.

La meta es evitar procesos de eutrofización crónica o eventos hipóxicos persistentes en sectores del vaso.

e. Criterio geotécnico y estructural: estabilidad de plataformas y márgenes.

El Vaso II presenta sedimentos finos saturados con baja capacidad portante. El dimensionamiento de plataformas debe basarse en estudios de mecánica de suelos que determinen consolidación, asentamientos diferenciales y estabilidad bajo cargas dinámicas.

Asimismo, el diseño debe incorporar protección de márgenes frente a oleaje inducido por buques y corrientes de hélice, evitando socavación en bordes con vegetación.

El indicador estructural clave será el control de asentamientos dentro de límites de servicio aceptables y la ausencia de erosión progresiva en márgenes naturales.

f. Criterio operativo: control de energía inducida por navegación

La operación dentro de un vaso interior requiere limitar velocidades de buques y definir rutas de navegación que minimicen oleaje inducido y turbulencia en zonas sensibles.

El dimensionamiento debe incluir simulaciones de maniobra y modelación de oleaje inducido, estableciendo límites máximos de velocidad y protocolos de tránsito.

El umbral será la no generación de velocidades de flujo o niveles de oleaje que superen la capacidad de resistencia de los bordes vegetados.

g. Criterio territorial y social: compatibilidad con usos existentes

El proyecto debe dimensionarse considerando accesos, vialidades y ferrocarriles con capacidad suficiente para evitar congestión urbana y afectaciones a actividades tradicionales.

Se requiere un estudio socioeconómico que cuantifique dependencia local del sistema lagunar y establezca medidas de evitación y compensación si corresponden.

El indicador social será la ausencia de afectación irreversible a medios de vida tradicionales y la aceptación social documentada mediante procesos participativos formales.

h. Criterio normativo y de gestión adaptativa

El dimensionamiento debe alinearse con la normativa vigente para humedales con manglar y con estándares internacionales de gestión portuaria sostenible.

Se requiere un esquema de gestión adaptativa que vincule fases de expansión con cumplimiento de indicadores ambientales y sociales medidos en campo. No deberá avanzarse a fases posteriores sin demostrar estabilidad en indicadores críticos.

4.4.1 Requisitos mínimos de ingeniería para el Vaso II

Desde la perspectiva específica del Vaso II, el diseño deberá incluir canal con sección optimizada que minimice alteración de circulación natural, dársenas con geometría que evite zonas muertas, rellenos limitados a lo estrictamente necesario, márgenes protegidos mediante soluciones de ingeniería ambientalmente compatibles y un plan de dragado con disposición controlada de sedimentos.

La operación deberá incorporar límites de velocidad, monitoreo continuo de calidad de agua y protocolos estrictos de manejo de residuos y agua de lastre.

4.4.2 Conclusión técnica

El adecuado dimensionamiento de la ampliación portuaria en la Laguna de Cuyutlán no es únicamente un problema de ingeniería civil o marítima; es un ejercicio de equilibrio entre capacidad logística y capacidad ecológica del sistema lagunar. La ampliación solo podrá considerarse técnicamente viable si demuestra, mediante estudios robustos y monitoreo verificable, que mantiene el régimen hidrodinámico, sedimentario y ecológico dentro de rangos compatibles con la permanencia del manglar, las islas centrales y los servicios ecosistémicos del Vaso II.

5.0 PROPUESTAS DE SOLUCIÓN AL DESARROLLO PORTUARIO EN LA LAGUNA DE CUYUTLÁN.

De acuerdo con los capítulos anteriores, la principal situación a resolver en las propuestas de ampliación del puerto de Manzanillo en la Laguna de Cuyutlán es la situación ambiental más que técnica, económica y operativa.

La situación principal por resolver en la ampliación del Puerto de Manzanillo dentro de la Laguna de Cuyutlán (Vaso II) es cómo incrementar capacidad portuaria sin provocar una transición de régimen físico-ambiental del vaso que vuelva el sistema hidráulicamente inestable, ambientalmente inviable, socialmente conflictivo y operativamente caro de mantener. En otras palabras: el proyecto no solo debe "caber" en el polígono; debe ser sostenible en el tiempo en un cuerpo lagunar somero, sedimentario y ecológicamente sensible.

a. Dimensión técnica.

Técnicamente, el reto central es que un puerto de gran escala requiere canales y dársenas con calados operativos, estructuras rígidas y plataformas extensas, pero el Vaso II es un sistema somero con sedimentos finos y dinámica de depósito. Esto genera un problema "de fondo": la obra tiende a crear un sistema que necesitará dragado de mantenimiento recurrente para evitar colmatación y mantener profundidades, y ese dragado puede retroalimentarse si se reconfigura la morfología del vaso y se afectan islotes que hoy modulan corrientes y sedimentación. En paralelo, las plataformas sobre suelos blandos demandan soluciones geotécnicas robustas para controlar asentamientos diferenciales. Todo ello eleva complejidad, riesgo constructivo y costos de vida útil.

b. Dimensión ambiental.

Ambientalmente, el núcleo del problema es que el Vaso II forma parte de un humedal con manglar, planicies someras e islotes, donde la estabilidad ecológica depende de la circulación, el balance salino y la calidad del agua. La ampliación introduce presiones directas e indirectas: modificación de batimetría, resuspensión de sedimentos, alteración de tiempos de residencia del agua y potencial pérdida/fragmentación de hábitats. En el debate público reciente se ha señalado específicamente la amenaza al humedal, manglares y la remoción de islotes con valor ecológico y cultural.

De hecho, el principal "cuello de botella"[6] ambiental-institucional hoy es que SEMARNAT no autorizó el diseño presentado al considerar que implicaba impactos ambientales no evaluados y riesgos potencialmente irreversibles en el ecosistema del

[6] Ver Anexo A

Vaso II. Ese resolutivo convierte la compatibilidad ambiental (y la calidad técnica de la evaluación) en el problema inmediato a resolver para cualquier avance del proyecto.

c. Dimensión económica.

Económicamente, el dilema es que la expansión busca destrabar saturación y sostener el crecimiento logístico del puerto de Manzanillo, con inversiones públicas relevantes (por ejemplo, se ha reportado un monto de referencia de inversión pública para descongestionar y ampliar capacidad). Sin embargo, en un sistema lagunar somero los costos de largo plazo pueden dispararse por tres vías: dragados de mantenimiento frecuentes, obras adicionales de protección de márgenes y correcciones por asentamientos o inestabilidad del terreno. A esto se suma el costo económico de la conflictividad socioambiental: retrasos, litigios, rediseños y riesgos reputacionales, que incrementan el costo financiero del capital y deterioran certidumbre para operadores.

Además, la planeación económica del proyecto se apoya en metas de capacidad y terminales (se han comunicado públicamente terminales para contenedores, graneles y combustibles, con objetivos de capacidad para contenedores). Si esas metas obligan a un dimensionamiento que exceda la capacidad física del vaso, el proyecto puede volverse “caro de operar” aun si es “rentable en papel”.

d. Dimensión operativa.

Operativamente, el problema principal es garantizar que un recinto interior lagunar funcione con seguridad y eficiencia como puerto de gran escala. Eso implica: maniobrabilidad de buques, control de oleaje inducido, operación continua de terminales, confiabilidad energética, y, sobre todo, que la salida terrestre (carretera y ferrocarril) no se convierta en el nuevo cuello de botella. Parte del discurso público del proyecto enfatiza nuevas terminales, automatización progresiva y accesos ferroviarios prioritarios, con metas de entrada en operación hacia 2029 para la primera terminal; esto subraya que el reto operativo no termina en el muelle, sino en la logística integral.

De acuerdo con lo anterior, la ampliación necesita resolver un problema único pero multidimensional: diseñar un puerto que incremente capacidad sin transformar el Vaso II en un sistema hidráulicamente “dependiente” (dragados, mantenimiento y barreras) y ambientalmente degradado, porque eso terminaría debilitando la viabilidad regulatoria, elevando el costo total de vida, y comprometiendo la operación.

5.1 Estratégicas y Recomendaciones Técnicas de Rediseño para la Ampliación Portuaria en el Vaso II de la Laguna de Cuyutlán.

El análisis integral del sistema ambiental del Vaso II evidencia que la ampliación portuaria, en su configuración de gran escala, representa una intervención estructural capaz de modificar el régimen físico del sistema lagunar. La baja profundidad natural, el carácter hipersalino estacional, la limitada renovación hídrica y la presencia de manglar fragmentado configuran un subsistema con alta sensibilidad ante alteraciones geométricas e hidráulicas.

El principal riesgo identificado no es únicamente la pérdida directa de superficie, sino la transición de régimen físico del Vaso II, pasando de un sistema dominado por procesos naturales de baja energía y sedimentación difusa a un sistema parcialmente canalizado, con profundidades artificiales, energía inducida por navegación y mantenimiento hidráulico permanente.

La interacción entre dragado, eliminación o modificación de islotes centrales, incremento de tráfico marítimo y rigidización de márgenes puede inducir:

- Alteración persistente de patrones de circulación y tiempos de residencia.
- Redistribución sedimentaria no controlada y aumento de dragados de mantenimiento.
- Incremento de estrés salino o estratificación térmica en sectores específicos.
- Reducción progresiva de planicies someras funcionales.
- Mayor vulnerabilidad del manglar ante erosión y cambios en régimen de inundación.

Desde el enfoque de capacidad de carga ambiental, el Vaso II presenta límites estrechos para absorber transformaciones morfológicas extensivas sin comprometer su estabilidad ecológica.

Por tanto, la viabilidad ambiental del proyecto depende de un rediseño técnico que incorpore principios de adaptación al sistema receptor, y no de sustitución del régimen natural por un régimen completamente artificial.

5.1.1 Recomendaciones técnicas de rediseño.

5.1.1.1 Redimensionamiento gradual y por fases condicionadas.

El proyecto debe estructurarse en fases secuenciales vinculadas a indicadores ambientales verificables. La expansión inicial debería limitarse a un polígono reducido que permita evaluar respuesta hidrodinámica y sedimentaria real antes de escalar.

Cada fase deberá condicionarse al cumplimiento de parámetros ambientales definidos, tales como estabilidad del tiempo de residencia del agua, ausencia de pérdida neta de manglar y mantenimiento de calidad de agua dentro de rangos históricos.

Por tal motivo, la expansión debe dividirse en etapas discretas y secuenciales, de manera que la superficie intervenida, la longitud de muelles, el volumen de dragado y la capacidad operativa (por ejemplo, TEUs/año u otra métrica equivalente) crezcan únicamente cuando la etapa previa demuestre estabilidad ambiental bajo monitoreo. El criterio operativo es que ninguna etapa posterior puede iniciar construcción o puesta en operación si no se cumple, durante un periodo mínimo continuo, un conjunto de indicadores críticos del Vaso II dentro de rangos aceptables. El redimensionamiento en este esquema consiste en que la capacidad proyectada total se alcance solo si el sistema demuestra tolerancia ambiental real, y no únicamente mediante supuestos de diseño.

Este enfoque reduce riesgo de transición abrupta de régimen y permite ajustes adaptativos.

5.1.1.2 Optimización geométrica para minimizar alteración hidrodinámica

El diseño del canal y las dársenas debe buscar la mínima intervención necesaria para garantizar seguridad operativa, evitando profundizaciones extensivas innecesarias.

La geometría de canal, dársenas y plataformas debe dimensionarse para evitar incrementos significativos del tiempo de residencia del agua y para prevenir la creación de zonas de recirculación persistente o “zonas muertas”. El indicador central de cumplimiento será la variación del tiempo de residencia promedio (y su distribución espacial) en escenarios con proyecto comparados contra el estado base. Un redimensionamiento aceptable es aquel que mantiene patrones de circulación que evitan acumulación crónica de nutrientes, temperatura y salinidad en sectores sensibles, particularmente en márgenes con manglar y en zonas someras adyacentes a islotes.

Se recomienda:

- Reducir el ancho del canal al mínimo compatible con normas de navegación segura.
- Optimizar radios de giro mediante simulaciones de maniobra que eviten sobreexcavación.
- Mantener, en la medida de lo posible, islotes o estructuras naturales que funcionen como moduladores de corriente.

La geometría debe diseñarse con base en modelación hidrodinámica que demuestre estabilidad en circulación interna.

5.1.1.3 Conservación estratégica de islotes centrales

Los islotes centrales deben considerarse infraestructura ecológica natural. Su conservación parcial o total puede mantener patrones de disipación de energía y sedimentación que reduzcan impactos secundarios.

Si la ingeniería requiere modificar islotes, el redimensionamiento debe conservar o reemplazar su función morfodinámica. En términos prácticos, no se trata solo de “no tocar islotes”, sino de mantener el patrón de disipación de energía y de deposición que estabiliza el vaso. Si se prevé eliminación parcial, el criterio exige medidas de sustitución funcional como islotes de baja elevación, bermas sumergidas, soluciones de “infraestructura verde” o rediseño del trazo para mantener sombras hidrodinámicas. Si no se logra equivalencia funcional, se incrementa riesgo de erosión y colmatación, lo que obliga a redimensionar.

En caso de requerirse modificación, deberá evaluarse la posibilidad de:

- Reconfiguración parcial sin eliminación total.
- Creación de islotes artificiales compensatorios con función morfodinámica equivalente.
- Implementación de barreras hidráulicas de bajo impacto que sustituyan funciones naturales perdidas.

La eliminación total sin medidas compensatorias incrementa riesgo de erosión marginal.

5.1.1.4 Protección activa de bordes con manglar

El diseño debe incorporar soluciones de ingeniería costera ambientalmente compatibles para evitar socavación inducida por oleaje y corrientes de hélice.

El puerto debe dimensionarse de manera que no genere pérdida neta de cobertura funcional de manglar y no incremente el estrés hidráulico sobre bordes vegetados. El criterio de redimensionamiento incluye establecer franjas de amortiguamiento físico entre infraestructura rígida y bordes con manglar, limitar velocidades de navegación interna y diseñar la geometría de dársenas para reducir oleaje inducido y corrientes de hélice en proximidad a vegetación. La condición de avance por fases debe incluir estabilidad de indicadores del manglar, como regeneración, mortalidad, integridad de borde y ausencia de erosión progresiva.

Se recomienda:

- Establecer límites de velocidad estrictos dentro del vaso.
- Incorporar sistemas de disipación de energía en zonas críticas.

- Mantener franjas de amortiguamiento entre infraestructura rígida y manglar existente.

Además, debe implementarse un programa de restauración preventiva de manglar en sectores vulnerables.

5.1.1.5 Gestión avanzada de sedimentos.

El dragado inicial y de mantenimiento debe planificarse bajo un enfoque de balance sedimentario integral. Se recomienda:

- Caracterización geoquímica detallada de sedimentos.
- Disposición controlada fuera de zonas ecológicamente sensibles.
- Evaluación de reutilización para estabilización de plataformas o restauración ambiental.

El redimensionamiento debe incorporar un plan de manejo de sedimentos dragados que garantice que su disposición o reutilización no genera afectaciones secundarias a humedales, manglar o planicies someras. Se debe exigir trazabilidad de volúmenes, caracterización geoquímica, sitios de disposición o confinamiento, y demostrar que la logística de sedimentos no crea impactos indirectos equivalentes o mayores a los evitados por el rediseño.

Por otra parte, debe mantener un porcentaje significativo de planicies someras funcionales, ya que en un humedal lagunar estas zonas sostienen la mayor parte de la base trófica bentónica y la disponibilidad de alimento para avifauna. El criterio no es únicamente “conservar superficie”, sino conservar gradientes de profundidad y conectividad hidrológica. Esto implica que el diseño de canales y dársenas debe minimizar la conversión de áreas someras en áreas profundas de manera extensiva y evitar cortar corredores someros que sostienen la dinámica ecológica del Vaso II.

Asimismo, debe establecerse un umbral máximo anual de dragado de mantenimiento que no implique aumento progresivo. El proyecto debe fijar un presupuesto máximo anual de dragado de mantenimiento como condición de sostenibilidad operativa y ambiental. El dimensionamiento geométrico se considera aceptable si el volumen anual de dragado de mantenimiento permanece dentro de un rango estable y no presenta tendencia incremental conforme avanza la operación. Si la modelación y el monitoreo muestran aumento progresivo, la respuesta de redimensionamiento debe ser reducir áreas profundas, ajustar secciones del canal, conservar o recrear estructuras que modulen transporte de sedimentos y rediseñar la disposición de plataformas para evitar focos de colmatación.

5.1.1.6 Control de calidad de agua y monitoreo adaptativo.

El proyecto debe incluir una red permanente de monitoreo de salinidad, temperatura, oxígeno disuelto, turbidez y nutrientes.

Se deben definir valores gatillo operativos que obliguen a ajustar operaciones portuarias si se detectan tendencias negativas persistentes.

a. Límite de cambio aceptable en el tiempo de residencia del agua y en la circulación interna

La geometría de canal, dársenas y plataformas debe dimensionarse para evitar incrementos significativos del tiempo de residencia del agua y para prevenir la creación de zonas de recirculación persistente o “zonas muertas”. El indicador central de cumplimiento será la variación del tiempo de residencia promedio (y su distribución espacial) en escenarios con proyecto comparados contra el estado base. Un redimensionamiento aceptable es aquel que mantiene patrones de circulación que evitan acumulación crónica de nutrientes, temperatura y salinidad en sectores sensibles, particularmente en márgenes con manglar y en zonas someras adyacentes a islotes.

b. Umbrales hidrosalinos: mantener el patrón estacional sin intensificar hipersalinidad ni estratificación persistente

El dimensionamiento debe demostrar que la obra no intensifica la hipersalinidad estacional ni genera estratificación salina/térmica persistente asociada a profundización artificial. Se debe establecer una línea base estacional y definir rangos de variación admisible, particularmente en estiaje. Si la operación o la geometría del proyecto tiende a elevar salinidad en zonas marginales o a prolongar estratificación con oxígeno bajo, el redimensionamiento debe ajustarse reduciendo profundidades, modificando alineamientos o incorporando elementos de mezcla y circulación.

c. Umbrales de calidad de agua con gatillos operativos obligatorios

Mantener dentro de la norma

El redimensionamiento debe incorporar un sistema de gestión adaptativa con umbrales medibles de turbidez, oxígeno disuelto, nutrientes y temperatura. Estos umbrales no deben quedar como metas generales, sino como valores gatillo asociados a acciones obligatorias, por ejemplo, disminuir ritmo de dragado, modificar ventanas de operación, instalar barreras anti-turbidez, reducir velocidades de navegación o detener actividades. Un puerto dimensionado adecuadamente en un vaso lagunar es aquel que mantiene el sistema dentro de un rango de calidad de agua compatible con el funcionamiento ecológico y evita condiciones hipóxicas recurrentes.

El monitoreo debe mantenerse durante toda la vida útil del proyecto.

5.1.1.7 Integración de infraestructura verde.

La ampliación puede incorporar soluciones basadas en naturaleza, tales como:

- Restauración de humedales adyacentes.
- Creación de zonas de transición vegetada entre plataformas y cuerpo lagunar.
- Sistemas de captación y tratamiento natural de escurrimientos pluviales.

Estas medidas pueden compensar parcialmente la pérdida de superficie natural y mejorar resiliencia del sistema.

5.1.1.8 Compatibilidad con escenarios de cambio climático

El diseño debe considerar elevación progresiva del nivel medio del mar y aumento en intensidad de eventos extremos.

Las plataformas deben proyectarse con cotas que incorporen márgenes de seguridad y no generen barreras rígidas que impidan migración natural del humedal.

5.1.1.9 Tráfico marítimo y energía inducida: capacidad operativa limitada por oleaje interno.

La capacidad por fases no debe depender únicamente de metros de muelle o patios, sino también del número de movimientos de buques y su tamaño, porque estos determinan el oleaje inducido. El redimensionamiento debe incluir límites progresivos de escala de buques y de frecuencia de maniobras dentro del vaso hasta que se demuestre que no hay erosión marginal ni aumento de turbidez crónico asociado al tráfico. En etapas tempranas, puede requerirse operación con buques y frecuencias más moderadas, ampliándose gradualmente.

5.1.1.10 Capacidad terrestre como condicionante: no activar más capacidad marítima que la que puede evacuar la red

El dimensionamiento debe garantizar que el crecimiento de capacidad marítima no exceda la capacidad real de evacuación terrestre (carretera y ferrocarril). Si la salida terrestre se congestiona, aumentan emisiones, ruido, conflictividad social y riesgo de accidentes, además de presiones urbanas. Por tanto, cada fase de crecimiento de terminales debe estar condicionada a que accesos viales y ferroviarios de esa fase estén construidos y operativos, y a que indicadores de congestión y emisiones locales se mantengan dentro de rangos aceptables.

5.1.2 Recomendación estratégica final.

El proyecto solo podrá considerarse ambientalmente compatible si se transforma de un esquema de ocupación extensiva a un esquema de intervención controlada, gradual y basada en evidencia científica modelada.

El rediseño debe orientarse a:

- Minimizar profundización innecesaria.
- Mantener funciones morfodinámicas naturales.
- Proteger manglar y planicies someras.
- Limitar mantenimiento hidráulico crónico.
- Vincular expansión a desempeño ambiental verificable.

En un esquema de redimensionamiento adaptativo, la Etapa 1 podría limitar la huella y la capacidad operativa a un nivel inicial que permita calibrar modelos con datos reales y validar que no se alteran circulación, salinidad y calidad del agua más allá de umbrales. Solo si esa fase cumple, se habilitaría la Etapa 2 con mayor longitud de muelle, mayor superficie de patios y mayor frecuencia de buques, y así sucesivamente, siempre con los “candados” de desempeño.

En síntesis, el Vaso II no debe adaptarse al puerto; el puerto debe adaptarse a la capacidad física del Vaso II.

5.2 Propuestas Técnicas de Rediseño para la Ampliación Portuaria en el Vaso II de la Laguna de Cuyutlán.

Con base en lo anteriormente expuesto, se identifican una serie de alternativas generales de desarrollo del nuevo puerto de Manzanillo. Cabe destacar que el objetivo de las alternativas seleccionadas es reducir el elevado impacto que supondría su construcción sobre las islas del interior de la Laguna y sobre la hidrodinámica lagunar; así como el impacto para el colectivo pesquero.

5.2.1 Alternativa 1

Desde el punto de vista técnico, la alternativa representa una expansión portuaria interior sobre el vaso lagunar No. II de Cuyutlán, estructurada a partir de un nuevo frente de atraque lineal dispuesto paralelamente a la barra costera, con el objetivo de no afectar a las Islas Cocodrilo I y II.

Figura 5.1 Propuesta No. 1 del Desarrollo Portuario en la Laguna de Cuyutlán.

La Figura 5.1 muestra una alineación continua de muelles rectos con múltiples posiciones de atraque, asociadas a amplias explanadas de contenedores organizadas en módulos ortogonales. La geometría de patios es claramente reticular, con vialidades longitudinales y transversales que permiten circulación interna de equipo portuario pesado (grúas RTG o sistemas automatizados), y una zona central destinada a servicios operativos y control. La configuración se ha planteado como un desarrollo por etapas, dado que los módulos de patio se repiten con superficies del orden de decenas de miles de metros cuadrados, lo que indica una estrategia de crecimiento progresivo dentro del polígono de reserva.

Las áreas de navegación incorporan una dársena interior con un círculo de maniobra claramente delimitado con un diámetro de 800 m, para la operación de buques de 400 m de eslora con capacidad de giro asistido. Se plantea un canal interior curvo que conecta la zona de atraque con el cuerpo principal de la laguna implica la necesidad de dragado significativo tanto en canal como en la dársena de ciaboga. La solución plantea la navegación interna, lo que técnicamente reduce la exposición al oleaje, pero incrementa la dependencia del régimen hidrodinámico lagunar. El dimensionamiento de las dársenas de ciaboga considera maniobras seguras con el apoyo de remolcadores y márgenes laterales adecuados para evitar la deriva hacia la orilla de la dársena.

A diferencia de la propuesta original, esta se ha planteado de tal forma que no interfiera con las Islas Cocodrilo I y II, ya que se plantea el desarrollo portuario en la margen sur de la Lagun de Cuyutlán, en una franja paralela a la línea de costa, lo que requiere se realicen rellenos confinados entre la laguna y la barra arenosa.

La conexión terrestre se resuelve mediante vialidades que enlazan los patios de almacenamiento de las terminales con la infraestructura existente, sin embargo, las conexiones viales y de ferrocarril de la zona sur de desarrollo, presentan el problema que deben usar la infraestructura existente. Los tramos de carretera federal y viaducto que enlazan con la Barra de Campos solo disponen de un carril por sentido para la circulación de camiones y vehículos particulares, en caso de un aumento del flujo de camiones derivado de la construcción del puerto en Cuyutlán, sería necesario plantear el desarrollo de nueva infraestructura, de cara a garantizar un mínimo de 2 carriles por sentido.

Asimismo, se debe considerar que este viaducto carretero que enlaza con la Barra de Campos cruza por una la zona urbana en la que cohabitan el tráfico de camiones con el tráfico vehicular de los vecindarios anexos. La ejecución de un posible proyecto de ampliación de la infraestructura podría llevar a una situación de oposición social, por lo que quizás sería necesario plantear un viaducto carretero complementario a través del Vaso II de la Laguna.

Desde el punto de vista ambiental, la alternativa se implanta directamente sobre el sistema lagunar de alta sensibilidad ecológica. La transformación de superficies de agua somera en

explanadas implica la pérdida directa de hábitat acuático y la modificación del patrón de circulación hidrodinámica del vaso. El dragado de las áreas de navegación interna en la laguna alteraría el equilibrio sedimentario, pudiendo generar resuspensión de sedimentos finos y cambios en turbidez, salinidad y oxigenación. Al tratarse de una laguna conectada dinámicamente con el mar y con presencia de humedales y manglares en su entorno, cualquier modificación en secciones hidráulicas o en la geometría del vaso puede alterar tiempos de residencia del agua y gradientes salinos, con efectos potenciales en comunidades de peces, crustáceos y aves.

La ocupación de la franja contigua a la barra costera también modifica la función natural de amortiguamiento ante eventos extremos. El sistema lagunar y los manglares asociados actúan como disipadores de energía frente a tormentas y marejadas; al sustituir superficies naturales por infraestructura rígida, se incrementa la reflexión de energía y la dependencia de soluciones estructurales para control de inundaciones. Asimismo, la operación de las terminales de contenedores de gran escala introduce presiones permanentes como emisiones atmosféricas, ruido, iluminación nocturna y riesgo de derrames, lo que exige sistemas de manejo de aguas pluviales con tratamiento previo a descarga, planes de contingencia ambiental y monitoreo continuo de calidad de agua.

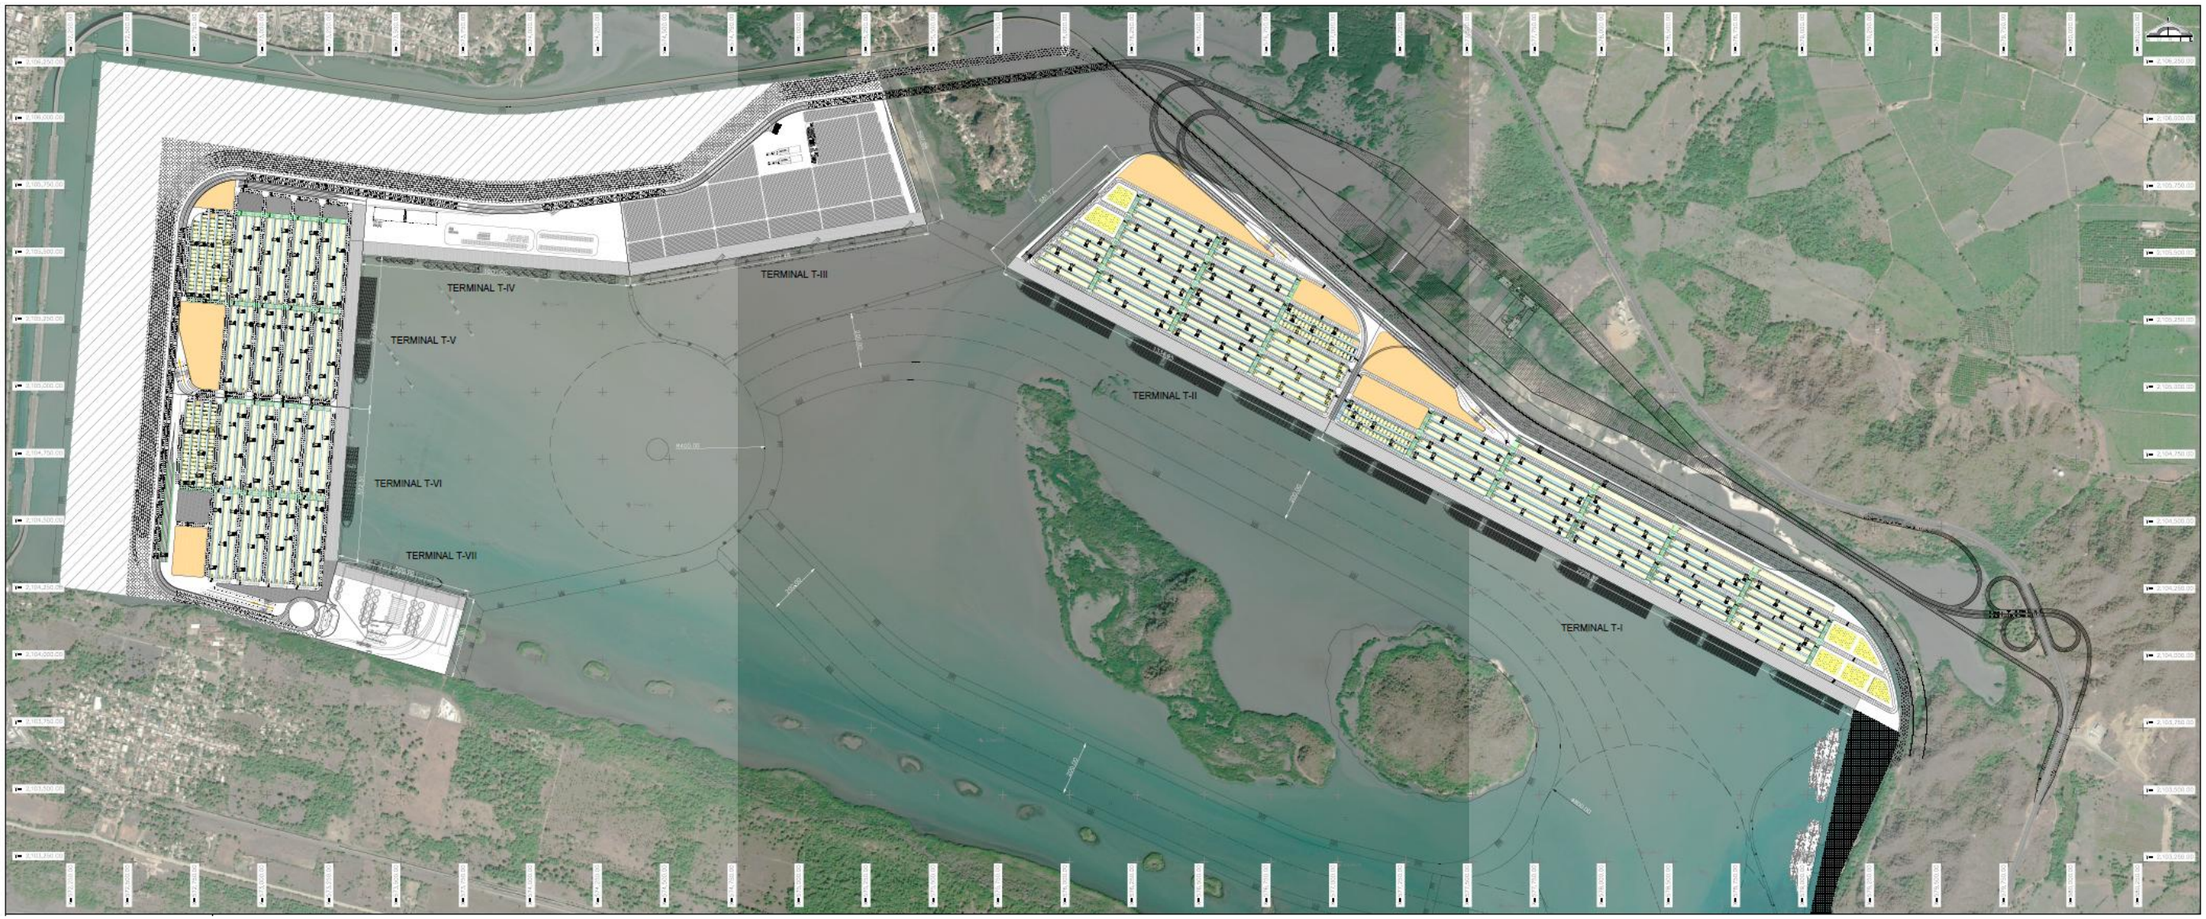
En términos de ordenamiento territorial, la propuesta requiere de una transición de uso de suelo predominantemente natural a industrial-portuario, con efectos acumulativos que deben evaluarse no sólo por la huella directa del relleno sino por la reorganización de flujos terrestres y marítimos, la generación de infraestructura complementaria y la posible expansión futura dentro del mismo polígono.

En síntesis, la alternativa de desarrollo en Cuyutlán No. I corresponde a una solución técnicamente coherente para ampliar capacidad portuaria mediante áreas interiores de navegación, frente lineal de atraque y amplios patios modulares, con operación potencial para buques de gran tamaño. Sin embargo, desde el punto de vista ambiental implica una reconfiguración del sistema lagunar que requiere control hidrodinámico y evaluación detallada para asegurar su estabilidad.

5.2.2 Alternativa 2

Desde el punto de vista técnico, esta segunda alternativa muestra una configuración distinta respecto a la primera, al concentrar el desarrollo en un esquema más estructurado en torno a la dársena central de ciaboga y un frente de atraque segmentado por terminales en el costado oeste del vaso No. II de la laguna. El diseño presenta muelles en escuadra que genera una envolvente casi ortogonal alrededor del área operativa, lo que permite múltiples posiciones de atraque distribuidas en tramos rectos. Esta geometría facilita la especialización funcional por terminal y la posible concesión por fases, ya que cada tramo puede operar relativamente independiente del resto.

Figura 5.2 Propuesta No. 2 del Desarrollo Portuario en la Laguna de Cuyutlán.



Las áreas de navegación interior se integran al sistema lagunar existente, lo que indica que la alternativa mantiene el concepto de navegación interior, pero con una organización espacial más definida y jerarquizada. La dársena de ciaboga con un diámetro de 800 m se garantiza radios de giro suficientes y con los márgenes de seguridad adecuados dentro del vaso No. II de la laguna.

La alternativa No. 2 evidencia un esquema de patios modulares bien organizados, con una retícula de almacenamiento alineada paralelamente al frente de atraque. Se presentan conexiones viales en el extremo sur que articula el recinto con infraestructura externa, así como un distribuidor vehicular principal. La disposición sugiere una planificación logística integral que contempla accesos controlados y posible integración ferroviaria futura.

Desde el punto de vista constructivo, esta alternativa implica igualmente un volumen significativo de dragado para conformar las dársenas y canales de navegación. La forma más compacta del vaso podría optimizar los volúmenes respecto a una configuración más extendida, aunque concentraría mayores profundidades en una zona definida. El relleno para conformar las explanadas portuarias ocupa una superficie importante entre la laguna y la zona terrestre existente, lo que implica estabilización de suelos, sistemas de contención perimetral y probablemente estructuras tipo tablestacado anclado o muelle sobre pilotes dependiendo de la profundidad final proyectada.

En términos ambientales, la segunda alternativa mantiene una intervención directa sobre el sistema lagunar de Cuyutlán, con transformación de áreas actualmente acuáticas en plataformas portuarias y modificación de la morfología interna del vaso. Sin embargo, al concentrar la dársena en un espacio más claramente delimitado y estructurado, podría generar un patrón hidrodinámico más predecible que una expansión longitudinal extensa. Aun así, el dragado altera los gradientes de salinidad, la circulación interna y la dinámica de sedimentos, pudiendo modificar tiempos de residencia del agua y procesos ecológicos asociados.

La ocupación de superficie lagunar representa pérdida directa de hábitat acuático y potencial afectación a zonas de alimentación y reproducción de especies. Asimismo, la creación de bordos y muros perimetrales modifica la conectividad entre subvasos de la laguna y puede alterar intercambios entre los ciclos de marea. La concentración de infraestructura en el oeste de la laguna podría reducir la fragmentación espacial del ecosistema comparado con un esquema más disperso, pero intensifica la presión local en el área intervenida.

Durante la fase constructiva, los impactos principales estarían asociados a la resuspensión de sedimentos, incremento de turbidez, generación de ruido subacuático y tránsito de maquinaria pesada. En operación, las terminales introducirían fuentes permanentes de emisiones atmosféricas, ruido, iluminación nocturna y riesgo de derrames, especialmente si se consideran múltiples terminales operando simultáneamente. La magnitud del patio y el número de posiciones de atraque sugieren una capacidad significativa, lo que implica aumento en tráfico marítimo y terrestre, con efectos acumulativos sobre calidad del aire y entorno social cercano.

En términos comparativos, esta segunda alternativa parece técnicamente más ordenada y funcionalmente sectorizada, con mejor definición de las áreas de navegación interna, lo que puede traducirse en mayor eficiencia náutica y operativa. Ambientalmente, aunque la huella directa sigue siendo considerable, la configuración compacta podría facilitar la implementación de medidas de mitigación y monitoreo al concentrar la intervención en un polígono claramente definido. No obstante, la alteración estructural del sistema lagunar continúa siendo significativa y requeriría estudios hidrodinámicos y ecológicos detallados para evaluar efectos acumulativos y de largo plazo.

5.2.3 Alternativa 3

Desde el punto de vista técnico, la tercera alternativa es similar a la segunda alternativa, la principal diferencia es que el control aduanero se realiza en el interior de cada terminal, con lo cual se logra reducir la afectación hacia las zonas de mangle que existe en la laguna.

La configuración del frente de atraque es lineal en el costado norte y oeste de la laguna, con patios de contenedores adyacentes organizados en retícula ortogonal. Esto confirma que la tercera alternativa busca consolidar un corredor integrando por terminales especializadas de contenedores con las futuras terminales de hidrocarburos y posiblemente con el tráfico de cabotaje.

La presencia de áreas marcadas como “Áreas de Desarrollo Portuario” y la proximidad al Ejido de Campos evidencian que el proyecto se inserta en un entorno mixto industrial–rural. El esquema vial perimetral y el acceso principal sugieren una conexión directa con infraestructura terrestre estratégica, lo cual es coherente con una plataforma logística de gran escala. La organización espacial es más alargada que en la segunda alternativa, extendiéndose longitudinalmente a lo largo de la barra costera, pero con una dársena central que articula los distintos tipos de terminal.

Desde el punto de vista constructivo, esta opción es similar a la segunda alternativa implica.

En términos ambientales, la creación de las áreas de navegación interior altera el régimen natural de intercambio entre laguna y mar, modificando salinidades, corrientes, tiempos de residencia del agua y patrones de sedimentación. El incremento en energía hidráulica por efecto de mareas y oleaje penetrando al sistema puede cambiar hábitats acuáticos y afectar comunidades biológicas adaptadas a condiciones más estables.

Figura 5.3 Propuesta No. 3 del Desarrollo Portuario en la Laguna de Cuyutlán.

La pérdida directa de superficie lagunar por relleno es significativa, pero el impacto más relevante es el cambio en dinámica hidrodinámica. A ello se suma la incorporación de terminales energéticas y de hidrocarburos, que elevan el riesgo ambiental asociado a derrames, fugas o incidentes mayores. La proximidad a instalaciones como la regasificadora y la termoeléctrica refuerza el carácter industrial del polígono y la acumulación de riesgos tecnológicos en un mismo enclave.

Durante la fase constructiva, los impactos incluirían dragado masivo, disposición de sedimentos, incremento de turbidez, ruido subacuático y modificación de hábitats costeros. En operación, el tráfico marítimo sería más intenso y diverso que en las alternativas centradas solo en contenedores, incorporando buques tanque y graneleros de gran porte. Esto implica mayores exigencias en control de seguridad marítima, planes de contingencia y monitoreo ambiental continuo.

Comparativamente, esta tercera opción ofrece una mayor diversificación de cargas y una mejora eficiencia náutica. Sin embargo, ambientalmente representa la alteración profunda del sistema costero–lagunar similar a la segunda alternativa, al intervenir tanto el cuerpo de agua interior como la barra y la línea de costa marina. **Su viabilidad dependería en gran medida de estudios hidrodinámicos detallados, modelación de transporte de sedimentos y una evaluación ambiental estratégica que considere efectos acumulativos y sinérgicos con la infraestructura energética existente**.

5.2.4 Comparativa de Alternativas

La primera alternativa se caracteriza por un desarrollo longitudinal relativamente extendido sobre el vaso lagunar, con frentes de atraque lineales y patios modulares repetitivos. Desde el punto de vista operativo es una solución funcional y escalable, pero su geometría más dispersa tiende a generar mayores recorridos internos y potencial interferencia entre maniobras y zonas activas si el crecimiento no se gestiona por etapas claramente separadas. Su eficiencia es buena en términos de expansión progresiva, pero no necesariamente óptima en compactación logística.

Ambientalmente, la primera alternativa implica una ocupación extensa de superficie lagunar con rellenos relativamente distribuidos. La alteración hidrodinámica podría ser significativa porque se modifica una porción amplia del espejo de agua, ya que actualmente la laguna de Cuyutlán presenta amplias áreas con profundidades someras y con el desarrollo estas serán profundizadas. Asimismo, el impacto se concentra en pérdida de hábitat y modificación de circulación interna, pero mantiene la condición general de sistema lagunar cerrado. En términos relativos, su intervención es alta en superficie, pero moderada en transformación estructural del régimen costero.

Tabla 5.1 Comparación de Alternativas de Desarrollo Portuario en Cuyutlán

CRITERIO	ALTERNATIVA 1	ALTERNATIVA 2	ALTERNATIVA 3
Configuración general	Desarrollo longitudinal extendido sobre el vaso lagunar con frentes lineales continuos y patios modulares repetitivos.	Terminales especializadas con frentes sectorizados por terminal y organización más jerarquizada. Punto de revisión aduanero fuera del área operativa de terminales.	Terminales especializadas con frentes sectorizados por terminal y organización más jerarquizada. Punto de revisión aduanero dentro del área operativa de terminales.
Tipo de operación predominante	Principalmente contenedores.	Contenedores con organización modular optimizada.	Contenedores con organización modular optimizada.
Eficiencia náutica	Adecuada	Alta	Muy Alta
Eficiencia logística interna	Buena escalabilidad, pero mayor dispersión espacial y recorridos internos más largos.	Alta eficiencia por compactación y mejor organización de patios y accesos.	Alta eficiencia por compactación y mejor organización de patios y accesos.
Capacidad estratégica de crecimiento	Alta por expansión modular progresiva.	Alta, con posibilidad de concesiones por terminales definidas.	Muy alta; modelo de plataforma logística e industrial integral.
Intervención sobre superficie lagunar	Alta ocupación directa y relleno distribuido.	Alta, pero más concentrada espacialmente.	Alta, pero más concentrada espacialmente.
Alteración hidrodinámica	Modificación interna del vaso lagunar sin cambio estructural del régimen mar–laguna.	Similar a la Alternativa 1, pero potencialmente más controlable por concentración espacial.	Similar a la Alternativa 1, pero potencialmente más controlable por concentración espacial.
Impacto ecosistémico relativo	Muy alto; afecta laguna, barra costera y dinámica litoral.	Alto por pérdida de hábitat lagunar.	Alto por pérdida de hábitat lagunar.
Riesgos técnicos principales	Asentamientos en rellenos, dragado de mantenimiento, sedimentación interna.	Asentamientos en rellenos, dragado de mantenimiento, sedimentación interna.	Asentamientos en rellenos, dragado de mantenimiento, sedimentación interna.
Complejidad constructiva	Alta, principalmente por volumen de relleno y dragado.	Alta, principalmente por volumen de relleno y dragado.	Alta, principalmente por volumen de relleno y dragado.
Riesgo ambiental acumulativo	Medio–alto.	Medio–alto (ligeramente menor relativo).	Medio–alto (ligeramente menor relativo).
Balance eficiencia / impacto ambiental	Intermedio.	Máxima eficiencia estratégica, pero mayor impacto y riesgo ambiental.	Mejor equilibrio relativo entre eficiencia operativa e impacto.

La comparación entre alternativas muestra que, si bien existen diferencias en la magnitud y distribución de los impactos ambientales, la evaluación integral debe considerar no solo la intervención inicial, sino el comportamiento del sistema en el tiempo. En este sentido, las configuraciones que permiten un mayor control de procesos hidrodinámicos y una mejor organización operativa reducen la probabilidad de impactos acumulativos y reconfiguraciones futuras no evaluadas.

Sus principales riesgos técnicos radican en la estabilidad de rellenos sobre suelos blandos, el control de asentamientos diferenciales en las plataformas de almacenamiento de contenedores y el mantenimiento de profundidades operativas mediante dragado de mantenimiento periódico. También existe riesgo de sedimentación acelerada si la nueva geometría altera flujos internos.

La segunda alternativa presenta una configuración más compacta y sectorizada, con una dársena claramente definida y frentes organizados por terminales. Desde el punto de vista operativo, esta propuesta es más ordenada en términos portuarios. El dimensionamiento de las áreas de navegación, maniobra y frentes de atraque mejora la seguridad de navegación y facilita concesiones por módulos. Logísticamente, la disposición de los patios y las salidas con el nodo exterior de revisión aduanero sugieren recorridos más eficientes y menor dispersión espacial. Por ello, en términos de eficiencia operativa dentro de un esquema exclusivamente de contenedores, esta alternativa puede considerarse superior a la primera.

En el plano ambiental, aunque la superficie intervenida sigue siendo considerable, la concentración de la dársena en un polígono más definido podría generar un patrón hidrodinámico más predecible y acotar la fragmentación del ecosistema. En términos relativos, frente a la primera alternativa, la segunda podría implicar una intervención ambiental ligeramente menor en dispersión espacial, aunque no necesariamente menor en volumen de dragado profundo, su impacto es significativo, pero algo más contenido en términos de configuración. Sin embargo, la propuesta de dejar fuera la zona de control aduanera implica una mayor afectación a la zona de mangle.

Los riesgos técnicos principales se asocian al dragado profundo concentrado, a la estabilidad de taludes submarinos en una dársena amplia y a la necesidad de garantizar radios de giro seguros para buques de gran tamaño sin afectar estructuras adyacentes. También existe riesgo de congestión futura si el crecimiento supera la capacidad de la dársena central.

La tercera alternativa es la más ambiciosa y compleja. Desde el punto de vista operativo es la más versátil y la que potencialmente ofrece mayor capacidad total y diversificación de carga. La consideración de un doble canal de navegación interior, implementado un canal de acceso y otro de salida reduce la navegación interna y puede disminuir tiempos de tránsito. En términos de eficiencia macro–portuaria y conectividad marítima, es la opción de mayor alcance estratégico.

Sin embargo, ambientalmente, al igual que la alternativa dos, implica transformación estructural. Con el dragado de las áreas internas de la laguna modifica el régimen hidráulico natural, altera salinidades y transporte de sedimentos, y puede inducir procesos erosivos o cambios morfodinámicos en la barra costera. Comparativamente, es la alternativa también tiene una intervención ambiental relativa y para su implementación deberán realizarse tareas de mitigación y propuestas de reforestación de la zona de mangle.

Sus riesgos técnicos son similares a la opción dos, el control de sedimentación en las áreas de navegación interior, la interacción entre corrientes marinas y lagunares, y la gestión integral de riesgos asociados a hidrocarburos y GNL en proximidad a otras instalaciones industriales.

En síntesis, la alternativa con mayor eficiencia operativa especializada en contenedores es la tercera, por su configuración compacta y mejor organización náutica. Asimismo, es la alternativa con mayor eficiencia estratégica y diversificación de carga, aunque con mayor complejidad técnica.

Por otra parte, la alternativa que representa una transformación ecosistémica. La primera se sitúa en un punto intermedio en impacto ambiental, pero con menor optimización espacial que la segunda y la tercera.

5.3 Matriz de Evaluación

Con el objeto de identificar la alternativa de desarrollo portuario que presente el mejor equilibrio entre desempeño operativo, viabilidad ambiental y factibilidad técnica, se aplicó una metodología de Evaluación Multicriterio (EMC). Esta herramienta permite comparar opciones de proyecto mediante criterios estructurados y ponderados, incorporando variables técnicas, ambientales y de riesgo dentro de un marco sistemático y transparente.

La metodología parte del reconocimiento de que la selección de alternativa no puede sustentarse exclusivamente en criterios de capacidad operativa o expansión física, sino que debe considerar de manera integral la interacción del proyecto con el entorno costero–lagunar, así como los riesgos constructivos y operativos asociados a su implementación.

Para ello, se definieron tres dimensiones de análisis: Operativa–Logística, Ambiental y Riesgo Técnico–Constructivo, asignando a cada una un peso relativo en función de su relevancia estratégica dentro del contexto del proyecto.

5.3.1 Definición de Dimensiones y Ponderaciones

La ponderación global se estableció considerando el carácter portuario del proyecto, su ubicación en un sistema lagunar ambientalmente sensible y la magnitud de las obras marítimas requeridas.

La Dimensión Operativa–Logística recibió un peso del 40%, dado que el objetivo principal del proyecto es ampliar y optimizar la capacidad portuaria, garantizando eficiencia en maniobras, productividad logística y competitividad regional.

La Dimensión Ambiental se ponderó con 35%, reflejando la alta sensibilidad ecológica del sistema lagunar de Cuyutlán y la necesidad de minimizar impactos estructurales sobre el régimen hidrodinámico y los ecosistemas asociados.

La Dimensión de Riesgo Técnico–Constructivo se asignó con 25%, considerando la importancia de la factibilidad constructiva, la estabilidad geotécnica y la gestión de riesgos tecnológicos en infraestructura portuaria de gran escala.

La suma de estas ponderaciones asegura un equilibrio entre desempeño funcional y sostenibilidad territorial, coherentes con un proyecto de esta magnitud en zona ambientalmente sensible.

5.3.2 Subcriterios de Evaluación

5.3.2.1 Dimensión Operativa – Logística

a. Eficiencia náutica.

Evalúa el desempeño de la configuración portuaria desde el punto de vista de la navegación y maniobra de buques. Considera la geometría del canal de acceso, amplitud y ubicación del círculo de maniobra de la dársena de ciaboga, separación entre frentes de atraque y áreas de navegación, alineación de muelles respecto a corrientes y vientos dominantes, y grado de interferencia entre operaciones simultáneas de arribo y salida. Una alternativa con alta eficiencia náutica minimiza riesgos de colisión o varadura, reduce tiempos de maniobra y optimiza la capacidad operativa por ventana de marea.

b. Eficiencia logística interna.

Analiza la funcionalidad del diseño en términos de flujo terrestre y organización de patios. Incluye la disposición reticular de áreas de almacenamiento, distancias promedio de traslado interno, accesibilidad a puertas de entrada y salida, posibilidad de integración ferroviaria, segregación de flujos (carga, equipo, vehículos ligeros) y potencial para automatización. Una alta eficiencia logística se traduce en menores tiempos de ciclo, menor consumo energético interno y mayor productividad por hectárea.

c. Capacidad de crecimiento modular.

Valora la posibilidad de ampliar la infraestructura por etapas sin afectar la operación existente. Considera la disponibilidad de reservas territoriales, facilidad de extender frentes de atraque, continuidad estructural del diseño y viabilidad de desarrollar módulos independientes. Una alternativa con alta capacidad modular permite ajustar la inversión a la demanda real y reduce riesgos financieros y operativos.

d. Flexibilidad de tipos de carga.

Mide el grado en que la alternativa admite distintos segmentos de mercado portuario. Incluye la capacidad para recibir buques de diferentes tamaños y tipologías (contenedores, graneles, hidrocarburos), la posibilidad de adaptar patios y muelles a nuevas tecnologías y la resiliencia ante cambios en el comercio internacional. Una mayor flexibilidad incrementa la competitividad estratégica del puerto a largo plazo.

5.3.2.2 Dimensión Ambiental

a. Intervención sobre superficie lagunar

Evalúa la magnitud de ocupación directa del cuerpo de agua y humedales asociados mediante rellenos, conformación de explanadas o infraestructura permanente. Considera la superficie transformada y la pérdida directa de hábitat acuático o ribereño. A mayor superficie intervenida, mayor presión ecológica.

b. Alteración hidrodinámica

Analiza el grado en que la alternativa modifica la circulación natural del sistema lagunar y su intercambio con el mar. Incluye cambios en salinidad, tiempos de residencia del agua, transporte de sedimentos, energía de corrientes y estabilidad de la barra costera. Una alteración estructural (como la apertura de una nueva bocana) implica un impacto hidrodinámico mayor que una modificación interna del vaso.

c. Impacto ecosistémico acumulativo

Considera los efectos combinados del proyecto con infraestructura existente o proyectada en el entorno. Incluye presión sobre manglares, fauna acuática, aves migratorias, calidad del agua y servicios ecosistémicos como amortiguamiento ante tormentas. Este subcriterio integra tanto impacto directo como indirecto y de largo plazo.

5.3.2.3 Dimensión Riesgo Técnico – Constructivo

a. Complejidad constructiva

Evalúa la dificultad técnica asociada a la ejecución de obras marítimas y terrestres. Incluye volumen de dragado, necesidad de rompeolas o escolleras, estabilización de taludes, control de infiltraciones, cimentación en suelos blandos y/o duros, y coexistencia con infraestructura existente. A mayor complejidad, mayor probabilidad de sobrecostos y retrasos.

b. Riesgo geotécnico

Analiza la incertidumbre asociada al comportamiento de suelos y sedimentos en rellenos y cimentaciones. Considera la presencia de depósitos blandos, potencial de asentamientos diferenciales, licuación, consolidación primaria y secundaria, y estabilidad global de terraplenes.

c. Riesgo morfodinámico / sedimentación

Evalúa la probabilidad de cambios en patrones de erosión y depósito que afecten la navegabilidad o estabilidad costera. Incluye riesgo de azolve acelerado en canales y dársenas, erosión en bocanas, migración de barras arenosas y necesidad de dragado de mantenimiento intensivo.

d. Riesgo tecnológico (energéticos y materiales peligrosos)

Considera el riesgo asociado a la operación de terminales de hidrocarburos, GNL u otras sustancias peligrosas. Incluye probabilidad y consecuencias de derrames, incendios o explosiones, así como la complejidad de planes de contingencia y zonas de amortiguamiento industrial.

5.3.3 Sistema de Calificación.

Se utilizó una escala ordinal de cinco niveles, donde el valor 1 representa desempeño muy desfavorable o alto impacto/riesgo, y el valor 5 representa desempeño muy favorable o bajo impacto/riesgo. Las calificaciones se asignaron con base en análisis técnico comparativo de la configuración espacial, requerimientos constructivos y alcance funcional de cada alternativa.

En resumen, la escala utilizada es de 1 a 5, donde:
1 = Muy desfavorable
2 = Desfavorable
3 = Intermedio
4 = Favorable
5 = Muy favorable

El resultado final para cada alternativa se obtuvo mediante promedio ponderado, multiplicando cada calificación por el peso relativo del subcriterio y sumando los resultados parciales dentro de cada dimensión, para posteriormente integrar el valor global.

Tabla 5.2 Matriz de Evaluación Multicriterio del Proyecto de Desarrollo Portuario en Cuyutlán.

	Criterio	Peso	Alternativa		
			1	2	3
Dimensión Operativa – Logística	Eficiencia náutica	15%	3	4	4
	Eficiencia logística interna	10%	3	4	5
	Capacidad de crecimiento modular	10%	4	5	5
	Flexibilidad de tipos de carga	5%	5	5	5
	Subtotal Ponderado	**40%**	**3.50**	**4.38**	**4.63**
Dimensión Ambiental	Intervención sobre superficie lagunar	15%	2	2	2
	Alteración hidrodinámica	10%	3	2	2

5.3.4 Alcances y Limitaciones

La evaluación multicriterio constituye una herramienta comparativa preliminar que orienta la toma de decisión estratégica. No sustituye estudios de detalle hidrodinámicos, geotécnicos o ambientales específicos, los cuales deberán desarrollarse en fases posteriores para optimizar el diseño definitivo.

Sin embargo, el método permite identificar de manera estructurada la alternativa que ofrece el mejor balance entre eficiencia portuaria, viabilidad ambiental y control de riesgos, proporcionando sustento técnico a la selección recomendada.

5.3.5 Resultados de la Evaluación

Con base en el análisis técnico–operativo, ambiental y de riesgos constructivos desarrollado para las tres alternativas de expansión portuaria en Cuyutlán, se realizó una evaluación comparativa estructurada mediante metodología multicriterio ponderada, considerando eficiencia logística, desempeño náutico, magnitud de intervención ambiental y nivel de complejidad técnica.

La aplicación del modelo de ponderación arrojó los siguientes resultados globales:

- Alternativa 1: 8.59
- Alternativa 2: 9.46
- Alternativa 3: 9.71

La Alternativa 1 presenta una solución funcional y escalable, con adecuada capacidad de crecimiento modular; sin embargo, su configuración longitudinal genera mayor dispersión operativa y una ocupación extensa del vaso lagunar, lo que implica impactos ambientales relevantes sin alcanzar el nivel óptimo de eficiencia logística observado en otras configuraciones.

La Alternativa 3 implica una intervención de mayor escala sobre el sistema lagunar en comparación con las otras alternativas, particularmente por la reconfiguración geométrica del vaso y la modificación de patrones de circulación interna. No obstante, a diferencia de las alternativas con configuraciones parciales o dispersas, esta intervención se plantea bajo un enfoque integral de control hidrodinámico y estabilidad morfológica, lo que permite gestionar de manera más efectiva los impactos inducidos.

En este sentido, el impacto de la Alternativa 3 no se considera menor en términos absolutos, sino más controlable y predecible, siempre que el diseño definitivo se sustente en modelaciones hidrodinámicas, de transporte de sedimentos y de calidad del agua, que permitan definir medidas de mitigación, compensación y ajuste geométrico con base en evidencia técnica. Esta condición implica que su viabilidad ambiental estará sujeta a la validación de dichos estudios, a fin de demostrar la compatibilidad del proyecto con el funcionamiento del sistema lagunar.

Desde el punto de vista ambiental, la Alternativa 2 presenta una menor intervención inicial y una configuración espacial más contenida, lo que puede traducirse en impactos más acotados en el corto plazo. Sin embargo, la Alternativa 3, al plantear una reconfiguración integral del sistema portuario, permite reducir presiones operativas futuras, evitar soluciones parciales y disminuir la probabilidad de impactos acumulativos no controlados en el mediano y largo plazo.

En este contexto, si bien la Alternativa 2 presenta ventajas en términos de intervención inicial, la Alternativa 3 ofrece una solución estructural más consistente con la evolución del sistema portuario, al mejorar la eficiencia sistémica, incrementar la resiliencia operativa y reducir la probabilidad de reconfiguraciones futuras no evaluadas ambientalmente.

El análisis ponderado posiciona a la Alternativa 3 como la opción de mayor viabilidad técnica, ambiental y operativa relativa, al ofrecer un mejor balance integral entre capacidad portuaria, eficiencia logística y gestión de riesgos, bajo el entendido de que los impactos asociados a su implementación pueden ser prevenidos, mitigados o compensados mediante el desarrollo de ingeniería de detalle y estudios ambientales específicos.

Finalmente, es importante señalar que la selección de la alternativa con base en la presente evaluación no constituye una validación automática de su viabilidad ambiental, sino una base técnica para el desarrollo del proyecto definitivo, el cual deberá ser evaluado conforme a la normatividad aplicable y a los requerimientos de la autoridad ambiental competente.

5.3.6 Selección de Alternativa

Con base en los resultados obtenidos mediante la Evaluación Multicriterio y el análisis técnico integral desarrollado, se concluye que la Alternativa 3 representa la opción más viable para el desarrollo portuario en la Laguna de Cuyutlán, al ofrecer el mejor desempeño integral en términos de capacidad operativa, eficiencia logística, viabilidad técnica y gestión de riesgos.

Si bien la Alternativa 2 presenta ventajas en términos de menor intervención inicial y una configuración espacial más contenida, dichas condiciones no resultan suficientes para garantizar el desempeño del sistema portuario en escenarios de crecimiento sostenido, ni para evitar presiones operativas que puedan derivar en impactos indirectos o acumulativos en el mediano y largo plazo.

En contraste, la Alternativa 3 plantea una solución estructural de mayor alcance, que permite optimizar la organización funcional del puerto, mejorar el desempeño náutico, incrementar la capacidad efectiva del sistema y fortalecer su resiliencia ante variaciones en la demanda y condiciones operativas.

Desde la perspectiva ambiental, la selección de la Alternativa 3 no se sustenta en una menor magnitud de impacto en términos absolutos, sino en la posibilidad de gestionar dichos impactos de manera más controlada, predecible y técnicamente sustentada, mediante el desarrollo de estudios especializados y la incorporación de criterios de diseño orientados a la estabilidad hidrodinámica y morfológica del sistema lagunar.

En este sentido, se considera que la Alternativa 3 ofrece un mejor balance entre desarrollo portuario y sostenibilidad ambiental en el largo plazo, al reducir la probabilidad de

reconfiguraciones futuras no evaluadas y permitir una gestión más eficiente de los procesos físicos y operativos del sistema.

No obstante, es importante señalar que la selección de esta alternativa no constituye una validación automática de su viabilidad ambiental, sino una base técnica para el desarrollo del proyecto definitivo, el cual deberá ser sometido a evaluación conforme a la normatividad aplicable, incorporando estudios de detalle que permitan verificar la compatibilidad del diseño con el sistema lagunar.

Dichos estudios deberán incluir, entre otros, modelación hidrodinámica, análisis de transporte de sedimentos, evaluación de calidad del agua y análisis de impactos acumulativos, a fin de asegurar que los efectos del proyecto puedan ser prevenidos, mitigados o compensados de manera verificable.

En consecuencia, desde una perspectiva técnica, ambiental y estratégica, se recomienda seleccionar la Alternativa 3 como esquema base para el desarrollo del proyecto, sujeta al cumplimiento de los estudios y condiciones anteriormente señalados.

6.0 PROPUESTA DE DESARROLLO PORTUARIO EN LA LAGUNA DE CUYUTLÁN.

Tomando en consideración los resultados obtenidos de la evaluación comparativa multicriterio, se acuerda seleccionar la alternativa 3 como la más adecuada para el desarrollo del nuevo puerto de la Laguna de Cuyutlán.

6.1 Caracterización y Diseño de las Instalaciones Portuarias.

6.1.1 Buque De Diseño.

6.1.1.1 Antecedentes.

El comercio exterior, tal y como lo conocemos fue impulsado por el explosivo aumento del transporte marítimo pos Segunda Guerra Mundial. En la actualidad, parte importante de las importaciones y exportaciones de los países se hace por vía marítima, ya que es un medio de transporte de carga eficiente y económicamente conveniente. Entre las diversas formas existentes de comercio marítimo, el contenedor representa una de las más eficaces y seguras.

El contenedor es ampliamente utilizado como forma de importar y exportar diferentes bienes (carga general). Actualmente existen empresas navieras que operan buques portacontenedores en rutas estándares con una frecuencia establecida. El proceso de implementación del contenedor fue conocido como contenerización[7] y permitió la automatización del manejo de la carga unitaria y un aumento sustancial en la productividad del comercio marítimo. El contenedor y los gigantescos buques que los transportan, son el resultado de un desarrollo tecnológico que llevó décadas.

1. Situación Pre-contenerización.

Previo al contenedor, el transporte marítimo de carga era muy diferente. Los barcos se cargaban de forma manual y las faenas se apoyaban con pescantes, cintas transportadoras y grúas para alivianar la alta carga física asociada. Esto implicaba largas estadías en puerto, una embarcación podía estar amarrada al muelle alrededor de una semana mientras se descargaban y cargaban los bienes transportados. En términos de costo, la tendencia era similar, entre un 60% a 75% del valor de trasladar carga por vía marítima, era única y exclusivamente por los largos periodos que el barco estaba detenido, ver Figura 6.1.

Las condiciones laborales de los trabajadores portuarios eran muy deficientes. Los turnos eran inciertos, el trabajo era informal y existían mafias en donde los capataces le cobraban a los mismos trabajadores para seleccionarlos. Levinson (2016) afirma que, de 51.000 estibadores

[7] La contenedorización es un sistema de transporte intermodal de mercancías que utiliza contenedores intermodales (también llamados contenedores de envío o contenedores ISO).

registrados en Nueva York, solo algunos pocos eran contratados a jornada completa, mientras que la gran mayoría eran casuales o informales.

Figura 6.1 Actividades de Carga y Descarga previo a la Contenerización.

Fuente: www.zarca.es.

El descontento y malestar en los sindicatos se manifestaba en constantes protestas que impactaban la eficiencia de la industria. Los trabajadores portuarios representaban la vanguardia del radicalismo sindical, entre los años 1948-1952 se perdieron 1MM de días hombre por

concepto de protestas en Gran Bretaña. La precariedad de los sueldos generaba altos índices de robo de mercancías por parte de los mismos trabajadores, que lo justificaban como una forma de complementar sus bajos ingresos. Adicionalmente, la gran cantidad de trabajadores dependientes de la industria producía una férrea resistencia a cualquier modernización que implicara disminución de trabajadores.

La solución era conocida; en vez de manejar la carga de forma separada en cientos de distintos tamaños y formas se planteó mover toda la carga dentro de cajas de mayor tamaño. A pesar de la simpleza del concepto, su implementación y desarrollo llevó décadas, pero significó un cambio radical en la industria marítima.

El principal precursor y conocido como el inventor de este sistema es Malcom McLean, ver Figura 6.2, quien fue el fundador de SeaLand, una de las primeras navieras de portacontenedores. La naviera Matson también fue pionera, pero su estrategia era totalmente distinta a la de Sealand.

Figura 6.2 Evolución de la Contenerización.

Nota: (a) Malcom McLean, (b) Terminal moderna de carga contenerizada, (c) Primer buque portacontenedores SS Ideal-X (Eslora: 160 m, Manga: 9.10 m y Puntal: 21 m), (d) Portacontenedores moderno (Tipo: ULCS Eslora: 400 m, Manga: 59 m y Calado: 16 m),
Fuente: Elaboración propia con información de www.panoramamaritimoylogistico.com y www.merchantnavydecoded.com.

En 1956, Sealand marcó uno de los hitos más importantes de la industria con el zarpe del Ideal-X (ver Figura 4.2), desde Nueva Jersey a Houston, transportando 58 contenedores. Este fue el primer trayecto de un buque portacontenedores y marcó lo que sería el futuro de esta industria, en donde el foco ya no estaría en la navegación, sino que en el manejo y transporte de carga. El desarrollo de tecnología de SeaLand se basaban en la experiencia e intuición de sus profesionales, quienes tenían un enfoque práctico al momento de diseñar.

Mientras tanto, Matson, naviera experimentada en el rubro, centraba sus desarrollos desde una perspectiva teórica. Financió la investigación académica, enfocada en el manejo de carga y cómo hacer este proceso más eficiente. Por ejemplo, fueron capaces de precisar que contenerizando su ruta California-Hawaii con contenedores de 20 y 25 pies podían reducir sus costos a la mitad. Los tamaños escogidos de contenedor permitían maximizar el uso de las grúas.

La implementación del contenedor siguió su curso con distintos desarrollos y nuevos actores, que vieron en esta tecnología una forma de mejorar lo ineficiente que era el manejo y movimiento de carga no contenerizada, ver Figura 6.3. La oposición por parte de los trabajadores portuarios era enérgica y no permitió inicialmente aprovechar la automatización inherente al contenedor. Los sindicatos obligaron a saturar las faenas con personal innecesario. Gradualmente, esto se fue ajustando hasta que se llegó al equilibrio en donde en los patios de carga se encontraban con el personal estrictamente necesario.

Figura 6.3 El Primer Contenedor.

Fuente: www.bbc.com.

Un acontecimiento histórico importante en el desarrollo del contenedor fue la guerra de Vietnam. A finales de 1965, posterior a una inspección en terreno efectuada por SeaLand a las instalaciones del ejército de Estados Unidos en Vietnam, se determinó que la logística completa se podía optimizar mediante la contenerización. El ejército decidió subcontratar el servicio completo, debido a su desconocimiento del tema. SeaLand se adjudica la licitación, porque ofrecía el suministro completo desde los buques y contenedores hasta la infraestructura portuaria y terrestre necesaria para el manejo de carga. Además, cobraba una tarifa de flete fija por tonelada trasladada. Gracias a esto, SeaLand estableció un servicio semanal de movimiento de carga contenerizada entre Estados Unidos y Vietnam, haciendo paradas intermedias en Filipinas y Japón. Esto la convierte en la primera empresa en operar un servicio internacional de contenedores, de forma similar a lo que hace hoy en día.

2. Proceso de Estandarización

La estandarización de los buques, los contenedores y el manejo de carga fue un proceso extenso y costoso. Estandarizar sobrepasaba el dominio de los buques, establecer medidas estándar del contenedor iba a generar una sinergia entre el transporte marítimo y terrestre, con consecuencias insospechadas para el comercio internacional. Esto es conocido como intermodalidad y se define básicamente como la articulación entre distintos medios de transporte utilizando una única unidad de carga, generalmente un contenedor.

Posterior al éxito del SS Ideal-X, McLean decidió transformar seis cargueros que serían la primera generación de buques portacontenedores. Era necesario aumentar la capacidad de carga mediante una estiba segura. SeaLand diseñó e implementó, el primer sistema de celdas que cumplía con estos requerimientos y que consistía en un grupo de guías verticales que dirigían al contenedor hasta su posición final. También, le daban firmeza al contenedor evitando cualquier desplazamiento debido a los movimientos de la embarcación en altamar. El sistema tenía una capacidad de 226 contenedores, tres veces superior al SS Ideal-X. Este principio de operación basado en celdas se utiliza hasta la actualidad, debido a su versatilidad y facilidad de operación.

Cuando el contenedor llegaba a su posición final, se requería un sistema de agarre, que permitiera fijar los contenedores, tanto entre sí como a la cubierta. SeaLand diseñó el primer sistema de conos semiautomático que permitía afirmar y soltar de forma rápida los contenedores a bordo y/o en los remolques de los camiones, mediante la activación de una palanca, agilizando el proceso de carga y descarga. Al igual que las celdas estos conos se siguen usando, aunque, en la actualidad son completamente automáticos.

El tiempo demostró que las grúas debían estar en tierra objeto mejorar los tiempos de carga y descarga, aumentando la capacidad de manejar los contenedores y, por ende, potenciar la intermodalidad. Uno de los primeros sistemas de manejo de carga con grúas terrestres fue el Seatrain system, el cual movía los contenedores a bordo a través de unos rieles y utilizaba una

cuna de levante para estos. Su capacidad máxima era de 125 ton. Posteriormente, se determinó que era más eficiente que el movimiento lateral lo tuvieran las grúas y no el contenedor, siendo esta la forma actual de funcionamiento.

En 1958, algunas compañías navieras ya estaban transportando contenedores, sin embargo, los beneficios aún no eran visibles en términos de costos, debido a la falta de estandarización. La gran variedad de tamaños, formas y pesos que tenían los contenedores, no tendían hacia la intermodalidad y una mala estandarización no permitiría su implementación. Este proceso se inició en Estados Unidos, y una gran cantidad de stakeholders, tanto del ámbito público como privado, tenían intereses en su materialización.

La primera fase de estandarización fue impulsada por dos organizaciones distintas; la United States Maritime Administration (Marad) y la American Standard Asociation (ASA). La primera, una agencia gubernamental netamente marítima y la segunda, una organización privada no ligada exclusivamente al ámbito marítimo. La fase inicial generó una infinidad de distintas medidas; el ancho y la altura fueron rápidamente estandarizados, sin embargo, el largo quedó pendiente debido a la gran cantidad de medidas existentes. El ASA estableció una primera estandarización, basada en los largos existentes, siendo suficiente para los ferrocarriles y camiones, pero insuficiente para los barcos. El sistema de celdas no daba flexibilidad entre los largos muy distintos de contendores, lo que implicaba altos costos de readaptación del sistema. Es importante destacar que, desde sus inicios, el proceso se amplió para actores ajenos al ámbito marítimo, lo que permitió trabajar siempre en pos de la intermodalidad.

Esta primera fase de estandarización finalizó con la intervención y las gestiones de Herbert Hall, máxima autoridad de la ASA. Hall estimaba que, teniendo contenedores de 10, 20, 30 y 40 pies de largo y de 8 pies de ancho y altura se lograba una relación aritmética que generaba flexibilidad en la estiba de la carga al interior del contenedor. A pesar de la oposición, estas medidas fueron establecidas como el estándar de la industria en 1961. Esto perjudicó a Matson y SeaLand y favoreció a los que recién entraban al negocio, dando un nuevo impulso a la actividad, con bases sólidas que permitían la asignación de créditos y subsidios.

Si se quería lograr la intermodalidad era necesario estandarizar a nivel global. Para esto, la International Organization for Standarization (ISO) debía interceder y analizar la contenerización. Los patrones establecidos para Estados Unidos fueron la base para el resto del mundo. La discusión se centró en las falencias que podían afectar la intermodalidad. Pese a que las medidas estaban listas, había vacíos que debían ser estudiados.

Los portacontendores requieren grandes inversiones de capital para operar. El objetivo es minimizar las estadías en puerto y maximizar los tiempos en que la embarcación se encuentra en trayecto transportando carga. La correcta elección del sistema de enganche de contenedores era decisiva. Según Matson retrasos mínimos en el proceso de carga y descarga, podían significar pérdidas de hasta 4,000 dólares por buque al año. Cada empresa tenía un diseño propio y

presionaba para que su diseño fuera el estándar. Finalmente, en 1965, después de varias comisiones y distintas discusiones técnicas, se decidió estandarizar el sistema de conos semiautomático diseñado por SeaLand, debido a la sencillez del diseño y bajos costos de manufacturación.

La falta de definición respecto al peso máximo del contenedor generaba una gran cantidad de incidentes. Sin este dato, no se podía establecer tanto el grosor de las paredes donde iban instalados los conos y tampoco, la capacidad de carga máxima de grúa. Mediante la designación de un panel ad hoc, se estableció el grosor de las paredes y, por ende, los pesos aceptables por tamaño de contenedor y la capacidad de levante de grúa.

Los tamaños que ya utilizaban Matson y SeaLand, no fueron considerados, sin embargo, ellos siguieron operando con sus antiguos contenedores. Su preocupación no era la inversión que debían hacer para adaptarse, sino, más bien, las ineficiencias que este cambio les produciría en sus respectivas rutas de carga. Finalmente, la presión por obtener los subsidios los hizo ceder e ir migrando de manera paulatina a las medidas establecidas.

En 1970, el comité técnico de la ISO, finalmente, publicó lo que serían las medidas estándar de la industria. Esto significó un avance significativo a la intermodalidad entre compañías y medios de transporte.

Figura 6.4 Estandarización del Contenedor.

Fuente: www.pelicancontainers.com.

3. Consolidación de la industria

Posterior a la publicación de los estándares ISO, se continuó un proceso de desarrollo en donde cada vez se construyeron buques de mayor capacidad. Los barcos de primera generación tenían distintos sistemas de manejo de carga y todos eran cargueros de la segunda guerra mundial adaptados para el transporte de contenedores. El que no fueran diseñados para estos fines los hacía deficientes en términos de capacidad de contenedores, ya que la forma de los cascos no permitía el uso eficiente del fondo de las bodegas. Este problema se fue mejorando con el incremento de la manga en el pantoque de los cascos. Las velocidades de operación se van aumentando paulatinamente hasta los 24 nudos, velocidad de operación estándar actual con condiciones de mercado normal.

En la década de 1980, la industria se expandió y las economías de escala logradas, condujeron a la construcción de barcos de mayor capacidad, lo que permitió una disminución del costo por tonelada transportada.

El estándar Panamax se define en base a las dimensiones máximas que puede tener una embarcación que pretende transitar por este canal. En 1985, se alcanzó este estándar con buques capaces de cargar 4,000 TEU's[8] Posteriormente, se construyeron los buques Post Panamax con una manga mayor a 32.2 m, que debido a su incapacidad para cruzar el canal requerían mayor capacidad de carga para ser rentables. Una vez sobrepasado el umbral Panamax, el tamaño de los barcos aumentó cada vez más rápido generando importantes cambios en la infraestructura portuaria. El alcance de las 8,000 TEU's aumentó el calado de las embarcaciones y obligó a los puertos a eliminar estas restricciones.

En el 2006, la capacidad se incrementó a 12,500 TEU's, generándose la tercera generación de buques Post Panamax; los Very Large Containership (VLCS). Ingresan al mercado, con la presentación de los barcos clase Emma de Maersk, VLCS con capacidades entre los 11,000 y 14,500 TEU's. En el 2013, fueron presentados los Ultra Large Containership (ULCS) o clase Triple E, con capacidades de 18,000 TEU's y un largo de 400 m. Actualmente, los ULCS están en el rango de los 23,000 TEU's.

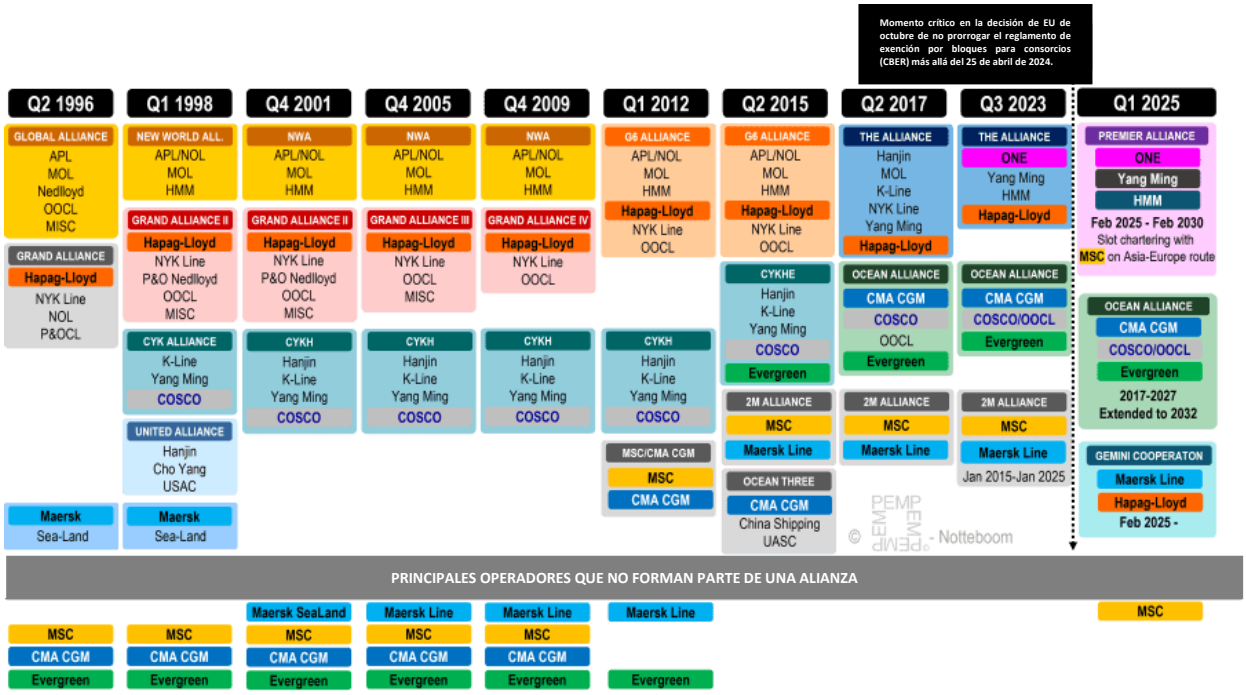
En el 2016, con la ampliación del canal de Panamá los buques Post Panamax pudieron transitar y surgió un nuevo estándar, el New Panamax. Estos barcos no pueden navegar por el canal, pero utilizan rutas alternativas con mayores distancias que son amortiguadas por las economías de escala.

[8] TEU es la sigla en inglés de "Twenty-foot Equivalent Unit", que se traduce como "unidad equivalente a veinte pies". Es una unidad de medida que se usa en el comercio exterior y en el transporte marítimo

6.1.1.2 Características del mercado de portacontenedores

Actualmente existe una gran cantidad de empresas navieras que operan servicios de portacontenedores, sin embargo, solo unas pocas concentran las mayores cuotas de mercado. En los últimos años y como respuesta al incremento de costos, debido, entre otras cosas, al endurecimiento en las normas de seguridad, operación y medioambientales, los armadores se han visto obligados a formar alianzas estratégicas. En el 2023, se hizo la última gran reestructuración de la industria y se crearon tres grandes alianzas, ver Figura 6.5.

Figura 6.5 Alianzas Estratégicas.



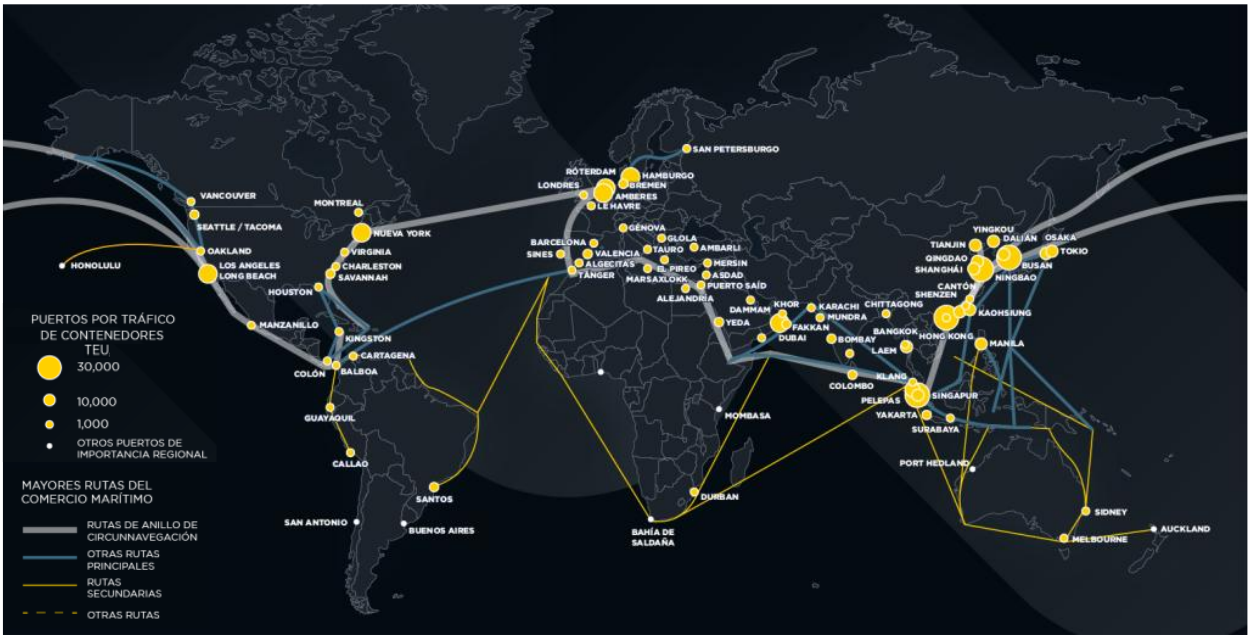
Fuente: www. porteconomicsmanagement.org.

Los servicios de portacontenedores proveen un itinerario regular de puertos fijados previamente, lo que es una diferencia sustancial con la carga a granel (granos, concentrado de hierro, etc.), que opera con itinerarios de puertos variables. La regularidad del servicio incide directamente en los costos fijos, ya que cuando hay desbalances entre la oferta y la demanda, los buques siguen navegando, pero en niveles de carga con márgenes de rentabilidad bajos o inclusive con pérdidas para el armador. El sector granelero mitiga esto, disminuyendo la velocidad de

operación o sacando de circulación el tonelaje menos eficiente. Los portacontenedores solo pueden disminuir la velocidad de operación, pero deben mantener la frecuencia de los barcos.

El movimiento de contenedores a nivel mundial se basa en itinerarios fijos de puertos, los cuales se clasifican en términos de distancia y dirección de movimiento. Existen más de 1,024 potenciales rutas de portacontenedores, las cuales son establecidas por los armadores de acuerdo con el tamaño de los buques disponibles, la demanda de carga y las características de los puertos de llamada. Las rutas se clasifican de acuerdo con la dirección de movimiento del barco. Están las rutas de Este a Oeste, de Sur a Norte y las intrarregionales, ver Figura 6.6. La ruta que actualmente mueve mayor cantidad de carga es la transpacífico, con un volumen contabilizado, en el 2019, de 30 MM de TEU's.

Figura 6.6 Principales Rutas Marítimas.



Fuente: www.blog.bego.ai.

En resumen, la introducción del contenedor en el transporte de carga marítima significó un cambio radical en la forma en que operaba la industria hasta ese momento. Las condiciones previas a la contenerización hacían inviable la masificación del comercio internacional.

Los inicios fueron difíciles, las presiones de ciertos grupos de poder y la incertidumbre, fueron factores que retrasaron su implementación. La estandarización permitió materializar la ejecución de este proceso y articular la forma en que la industria debía operar para disminuir sus

costos operacionales. Además, pero de forma indirecta, la estandarización consolidó la intermodalidad.

Con la estandarización la industria comenzó a crecer, produciendo un aumento sostenido en la capacidad de transporte de los buques. Existen distintas limitaciones de tamaño, basándose en la tolerancia de los buques para navegar por los tramos más estrechos de las rutas existentes.

En la actualidad la industria es una red compleja de rutas e itinerarios estándar, que no pueden ser modificados y que generan costos fijos de operación, que no existen en otros sectores del transporte marítimo. Sin embargo, los grandes volúmenes de carga transportados generan economías de escala que permiten mitigar estos problemas.

6.1.1.3 El Buque Portacontenedores.

Desde que en los años cincuenta se crearon los contenedores, los buques han aumentado exponencialmente su tamaño. Los buques portacontenedores son una parte importante de la cadena logística mundial y, por tanto, el tamaño y la eficiencia del navío se debe aumentar para mejorar las economías de escala.

Las aspiraciones por buques más grandes están siempre presentes. En las últimas décadas se motivaba a pensar en grandes buques portacontenedores, como el Malacca-Max (limitado por el calado del estrecho de Malacca). Se fue avanzando en el agrandamiento de los buques, incluyendo las mejoras tecnológicas. En el año 2008 los astilleros surcoreanos STX anunciaban que tenían diseñado un buque de 22.000 TEU, en 2011 se rumoreaba que Maersk ordenaría buques de 18.000 TEU, y de 20.000 TEU para 2014.

Todas estas estimaciones de grandes buques han sido superadas, y hoy navegan buques de hasta 24.000 TEU, adaptados a la tecnología y condicionantes actuales. Los buques significativos más grandes y la cantidad de buques de su serie suman 89 buques entre 18.000 y 24.000 TEU, siendo en su mayoría buques de MAERSK (35%), MSC (20%), COSCO (19%), EVERGREEN (12%), MOL (7%) y UASC (7%); asimismo resalta que hay encargado un total de 32 buques “MGX-24” o Megamax-24 (buques con 24 filas en 61,5 m de manga) para HMM, MSC y CMA-CGM. También se observa que los buques en servicio de entre 18.000 y 24.000 TEU indicados, tienen una eslora de 400 m, una manga entre 58,6 m y 61,5 m y un calado entre 16 y 16,5m. El MSC GÜLSÜN representa un hito, además de superar en tamaño con su capacidad de 23.756 TEU incorpora nuevas tecnologías para evitar accidentes, optimización del espacio y protección del océano y el ambiente.

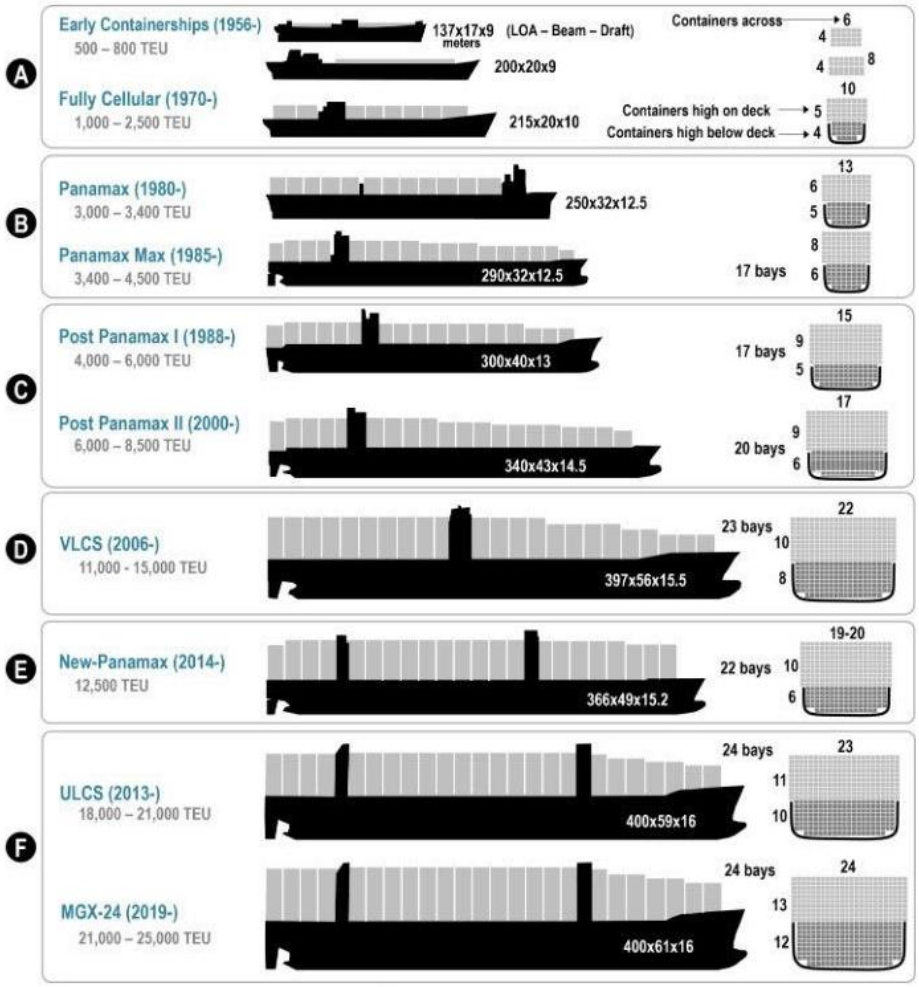
1. Tendencia en el Tamaño de los Portacontenedores.

Durante las últimas dos décadas, la capacidad de los buques portacontenedores se ha triplicado, y los astilleros cuentan ahora con navíos que pueden soportar hasta 23.000 TEU. A

pesar del crecimiento exponencial de este sector, algunos cuestionan si se pudiera alcanzar un límite, como sucedió con los buques graneleros.

Primero de todo, es importante entender por qué ha habido seis olas de cambios substanciales en los buques portacontenedores, cada una representada por una nueva generación de navíos, ver Figura 6.7.

Figura 6.7 Evolución de los Portacontenedores.



La primera generación consistió, básicamente, en buques graneleros con una capacidad de hasta 1,000 TEU's. No obstante, todo evolucionó rápidamente desde entonces. Los navíos continuaron aumentando su capacidad y sus dimensiones hasta que ya no podían pasar por el

Canal de Panamá, en 1985, con una capacidad que rondaba los 4,000 TEU's. Estos navíos se conocen como generación Panamax.

En 1988, los primeros buques se construyeron con una anchura de más de 32.3 metros, suponiendo los inicios de la generación post-Panamax de buques portacontenedores. Esto condujo a problemas infraestructurales en muchos puertos de todo el mundo, ya que tuvieron que invertir en grúas pórtico más grandes y dragar las zonas portuarias para tener el calado necesario para este tipo de buques.

A principios de los 2000, la demanda y el tamaño continuaban creciendo. Desde el 2001 hasta el 2006, el crecimiento del volumen comercial fue, de promedio, tres veces superior al del PIB. Así, las compañías navieras más punteras, que empezaron a hacer acuerdos estratégicos, vieron la necesidad de una nueva generación de buques portacontenedores. En el 2006, con el lanzamiento del Emma Mærsk, entró en servicio el primer buque portacontenedores de gran tamaño VLCS (Very Large Container Ships). Los buques portacontenedores de mayor tamaño reducían aún más el costo por TEU, lo que aumentó la demanda y, por tanto, impulsó los buques aún más grandes.

Este circuito de retroalimentación terminó cuando estalló la crisis financiera en el 2008 y la demanda empezó a decaer. Sin embargo, el poder comercial de los acuerdos y el ascenso de los mercados emergentes como China continuaban aumentando aún más el tamaño de los buques portacontenedores, a pesar de que la demanda no iba a la par. Así pues, diez años después, se lanzaron los buques portacontenedores Ultra Large Container Ship (ULCS), con capacidades superiores a 20,000 TEU's.

Hasta el año 2022, el buque portacontenedores más grande en cuanto a capacidad es el MSC Gülsün, con 23,756 TEU, 400 metros de eslora, 61.5 metros de manga y un calado de 16.5 metros, ver Figura 6.8. En junio de 2022, el astillero chino Hudong Zhonghua Shipbuilding entregó oficialmente a Evergreen el Ever Alot, ver Figura 6.11, el mayor buque portacontenedores construido hasta la fecha. Con una capacidad de 24.004 TEU, es el primero en superar la barrera de los 24.000 TEU's. El buque fue ordenado en noviembre de 2019 y pertenece a la clase A de Evergreen, una serie de 13 portacontenedores encargados por la naviera a tres astilleros asiáticos. En breve se entregará el MSC Tessa, con dimensiones similares al Ever Alot, pero con una capacidad ligeramente superior 24,116 TEU's.

Aunque la capacidad ha aumentado considerablemente, el tamaño de los últimos buques portacontenedores no ha cambiado mucho los últimos años

En mayo de 2022 había cerca de 900 portacontenedores en construcción o por encargo en todo el mundo con una capacidad total de 6.8 millones de TEU's. Los recientes pedidos realizados por las navieras nos dan una pista de la evolución del sector:

Figura 6.8 Portacontenedores MSC Gülsün.

Nota: El MSC Gülsün, en el momento de su botadura en 2019, era el buque portacontenedores más grande del mundo. Construido por Samsung Heavy Industries en Corea del Sur, tiene casi 61.5 m (201 pies 9 pulgadas) de manga y 399.9 m (1.312 pies 0 pulgadas) de eslora y un calado operativo de 16.5 m y un máximo de 17.7 m. Con un sistema de carga diseñado por MacGregor International AB, el barco tiene una capacidad de 23.756 contenedores (23.756 TEU's) en filas de 24 de ancho
Fuente: Mediterranean Shipping Company.

- En marzo de 2021, la propia Evergreen realizó un encargo de 20 portacontenedores de 15,000 TEU's de capacidad a entregar en 2024/2025.

- OOCL ordenó en septiembre de 2021 diez nuevos buques con una capacidad de 16,000 TEU's cada uno.

- Por su parte, MSC encargó en abril de 2021 cuatro ULCS de 24.100 TEU de capacidad a entregar en 2023. En abril de este año, ha ampliado el pedido con catorce nuevos buques de 8,000 TEU's y otras seis unidades de 7,900 TEU's, a entregar en 2025. En junio, sumó al encargo veinte nuevos buques, diez de 8,100 TEU's y 10 de 11,400 TEU's.

- En la misma línea, CMA-CGM ha encargado en junio de este año seis buques de 15,000 TEU's de capacidad que se entregarán en 2025.

De hecho, hasta un total de 561 portacontenedores fueron encargados en 2021. Comparados con los 114 en 2020 o los 107 en 2019, marcan una inflexión más que notable respecto a la tendencia de los últimos años. Estos pedidos nos permiten ver cómo está evolucionando el mercado de nuevos buques.

2. Factores Determinantes que Podrían Producir un Cambio en el Tamaño de los Buques Portacontenedores.

Para entender qué factores pueden llevar al desarrollo de una nueva generación de megabuques, es necesario revisar los factores determinantes y las interdependencias, que se pueden dividir en seis categorías:

- Tecnología
- Sostenibilidad
- Mercado
- Coste de la infraestructura
- Infraestructura portuaria
- Rutas marítimas

En la Figura 6.9 muestra varios factores para cada categoría y nuestra suposición sobre si conducirán a un aumento o descenso del tamaño de los buques.

Para predecir un desarrollo futuro, se han analizado las dimensiones de buques portacontenedores anteriores, de acuerdo con la base de datos de Lloyds. En la Figura 4.10 se muestran la eslora, la manga, el puntal y el calado en relación con la capacidad en TEU's.

Al analizar la relación entre las dimensiones de los buques portacontenedores y su capacidad en TEU podemos deducir las siguientes tendencias:

- El calado no cambia significativamente al superar los 12,000 TEU's. De hecho, parece que se estabiliza alrededor de los 16 y los 16.5 metros.

- El puntal parece fijarse en alrededor de 30 metros en buques de más de 12,000 TEU's, pero ha aumentado a 35 metros en los últimos ULCS (buques portacontenedores ultragrandes) con una capacidad mayor que 20,000 TEU's.

- La eslora se estabiliza en unos 400 metros en buques de más de 15,000 TEU's.

- Proporcionalmente, la manga es la dimensión que muestra un mayor crecimiento.

Figura 6.9 Factores Sobre si Conducirán a un Aumento o Descenso del Tamaño de los Buques Portacontenedores.

- La manga, la eslora y el puntal están aumentando claramente a intervalos, basándose en las nuevas filas de TEU's añadidas.

- El aumento de la capacidad en los VLCS y los ULCS está relacionada con los cambios de la eslora, el puntal y la manga, aunque es más significativo en esta última. Con respecto al calado, es la dimensión menos afectada en los megabuques actuales.

Analizando en conjunto la Figura 6.10, podemos apreciar que las dimensiones van en aumento con una capacidad mayor. No obstante, el gradiente está decreciendo en todas, lo que significa que se están consiguiendo mayores capacidades sin un aumento sustancial del tamaño del buque. De acuerdo con los últimos desarrollos de los buques, la manga parece la dimensión que mejor se amolda a la capacidad superior de TEU's en comparación con las demás dimensiones.

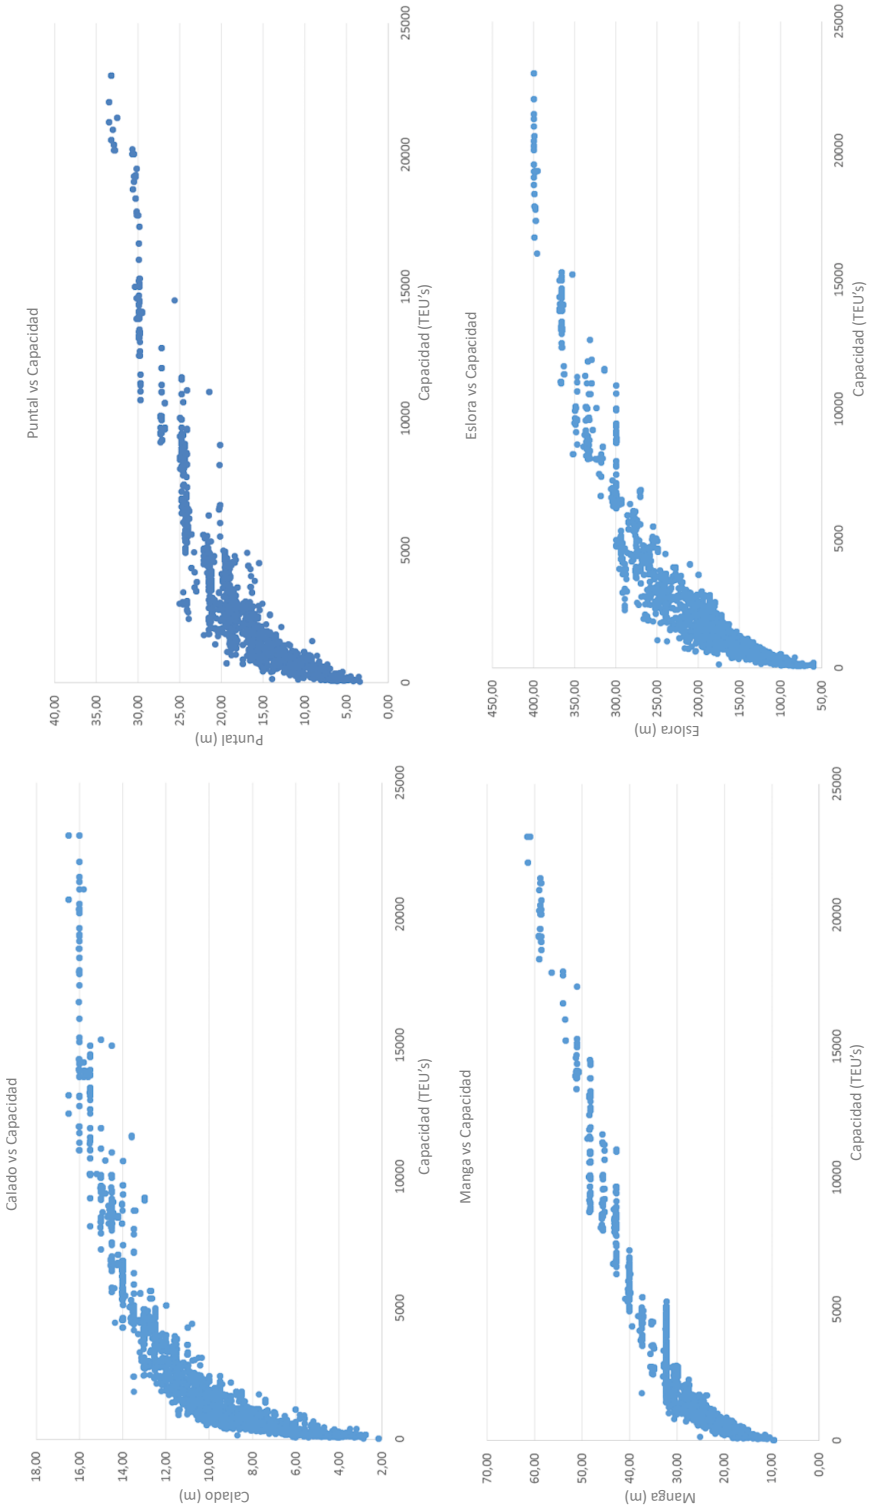


Figura 6.10 Relación Entre el Calado, Puntal, Manga, Eslora y la Capacidad (TEU) de los Buques Portacontenedores desde 1964.

Una vez que se han analizado las estadísticas precedentes, podemos extrapolar los resultados al futuro. Así pues, de acuerdo con la Figura 6.10, podemos estimar que, si no se produce un cambio significativo en la evolución del tamaño del buque, un buque portacontenedores con una capacidad de 30,000 TEU's no excedería los 17 metros de calado y la eslora apenas alcanzaría los 425 metros. Con respecto a la manga, las tendencias muestran un posible aumento de su dimensión, así que probablemente llegue a los 65 metros. A pesar de que el tamaño de los buques va en aumento, está claro que las dimensiones no van a cambiar mucho en proporción a la capacidad.

De hecho, no se espera un crecimiento sustancial del tamaño de los portacontenedores, siendo el límite estimado de 30,000 TEU's por varios motivos:

- Las restricciones físicas de las rutas y los puertos.
- Agotamiento de las economías de escala de los costos de navegación.
- Tendencias de demanda y económicas mundiales.

En resumen, la evolución de los buques portacontenedores no ha terminado. Basándonos en las estadísticas precedentes, podemos predecir las dimensiones de un buque portacontenedores con una capacidad de 30,000 TEU's. Sin embargo, cualquier alteración tecnológica podría cambiar esta evolución de manera importante. Situamos estas estimaciones en un contexto mayor al analizar diferentes factores determinantes y sus dependencias. Cualquier nueva generación de buques portacontenedores tendría que afrontar un número en declive de puertos capaces de atenderlos.

Otro factor importante para tener en cuenta es que los límites del tamaño de los buques portacontenedores parece mucho más condicionado por la estrategia comercial y las dimensiones del canal que por las limitaciones técnicas.

Los factores medioambientales podrían ser determinantes dada la actual crisis climática ocasionada por el calentamiento global.

Para concluir, es importante destacar que el tamaño ideal de portacontenedor dependerá mucho de la demanda mundial, que puede variar de forma significativa con los procesos de relocalización de empresas. También dependerá del mix energético, afectado por una elevada volatilidad a consecuencia de los cambios tecnológicos que llegarán para afrontar el cambio climático.

6.1.1.4 El Buque de Diseño.

Los portacontenedores más grandes del mundo tienen 400 metros de eslora y alrededor de 60 metros de manga. Es, más o menos, el límite superior actual para estos buques y hay una

buena cantidad de razones que impiden su crecimiento. Incluso, es poco probable que se vean buques portacontenedores mucho más grandes que los actuales.

Hay alrededor de 5,500 portacontenedores en el mundo y juntos son capaces de transportar 25 millones de TEU's. Las órdenes globales para nuevos buques aumentarán esa capacidad colectiva total en un gigantesco 25% en solo unos pocos años. Estamos viendo que se están construyendo muchos más portacontenedores ULCS, la proporción de naves nuevas que movilizan más de 14.000 TEU's es asombrosa.

Sólo en la última década, la capacidad promedio de un portacontenedor ha aumentado de menos de 3,000 TEU's a alrededor de 4,500 TEU's. Y actualmente hay más de 50 naves con una capacidad de 21,000 TEU's o más. Prácticamente todos ellos fueron construidos en los últimos cinco años.

Sin embargo, estos buques superan los límites incluso de los puertos más grandes del mundo, ver Tabla 6.1. Para cargar y descargar contenedores, las grúas deben cruzar completamente los buques y éstos también deben girar y pasar por los canales de Suez y Panamá, que tienen restricciones de tamaño.

También es crucial que eviten encallar. En algunos puertos, los buques más grandes están tan sumergidos en el agua que tocan el fondo y se deslizan a través del sedimento en lugar de flotar.

Para acomodar naves mayores que las más grandes que existen hoy, se requeriría de una gran revisión de la infraestructura portuaria, lo que sería increíblemente costoso. Los buques más grandes también están restringidos en cuanto a las rutas por las que navegan porque son muy vulnerables a las inclemencias del tiempo. Es por eso por lo que los buques de gran tamaño se acercan a la costa, para que no enfrenten grandes olas, es una cuestión de estabilidad[9].

Como es posible observar en la Tabla 6.1, la mayoría de los principales puertos en el movimiento de contenedores no son lo suficientemente amplios y profundos para albergar este tipo de portacontenedores. De hecho, sólo un puñado de naves con capacidades cercanas a los 20.000 TEU's han arribado a estos puertos.

[9] Cuando navegan directamente en una secuencia de olas, las naves pueden experimentar un fenómeno llamado balanceo paramétrico. Cuando las olas pasan a lo largo de un buque portacontenedores muy ancho, su proa y su popa pueden despejar el agua siempre que el peak de la ola esté en el punto medio del buque. Esto deja a la parte superior de la proa y la popa sin el apoyo del agua. La variación en este soporte, a medida que las olas pasan, puede hacer que el buque se balancee de forma extraña de un lado a otro.

Tabla 6.1 Top Mundial de los 30 Principales Puertos en 2023.

No.	Puerto	País	Profundidad (m)	Volumen (TEU's al año)
1	**Shanghái**	**China**	**-20**	**49,158,000**
2	Singapur	Singapur	Varía entre -7 hasta -16	39,012,954

4	Veracruz / Ampliación	México	-12.8 / -18	1,148,325

Fuente: Elaboración propia, 2025.

Además de todas las causas anteriores, hay un clima económico con el que lidiar. El precio del petróleo es extremadamente alto en este momento y que los portacontenedores más grandes requieren grandes volúmenes de combustible. Sin embargo, invertir en naves aún más grandes podría no ser la opción financiera más inteligente en el futuro. Aunque, en este momento estos costos están más que cubiertos por las astronómicas tarifas de flete en todo el mundo.

Para que los portacontenedores con una capacidad muy superior a 25,000 TEU's sean viables, la economía de operarlos tendría que cambiar.

El Canal de Suez probablemente siempre actuará como un cuello de botella para las naves que viajan desde Asia a Europa, pero no es imposible imaginar un buque de 30,000 TEU's o similar atravesando una ruta desde China, por ejemplo, a un puerto africano o latinoamericano en auge como es el caso del puerto de Manzanillo.

El límite de 24,000 TEU's en la capacidad de los buques portacontenedores que vemos hoy a nivel mundial es, más o menos, un reflejo de los límites económicos tanto como los de la infraestructura portuaria, la forma de las vías fluviales más transitadas del mundo y la ingeniería.

Figura 6.11 Portacontenedores Ever Alot.

Nota: Ever Alot es un buque portacontenedores a partir de 2022, el buque portacontenedores más grande del mundo tanto por TEU como por tonelaje bruto. El barco fue botado en junio de 2022. Tiene 61.5 metros (203 pies 5 pulgadas) de manga y 400 metros (1.312 pies 4 pulgadas) de eslora. El barco tiene una capacidad de 24,004 contenedores (24,004 TEU's). Ever Alot es operado por Evergreen Marine Corporation. Es el primer buque portacontenedores en tener una capacidad de 24.000 TEU.
Fuente: Evergreen Marine Corporation.

Finalmente, la ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán debe contemplar una flota de diseño que cubra los intereses comerciales del puerto a medio y largo plazo. Si bien parece claro que los buques SMX y VLCC están claramente definidos, se recomienda que, de cara a la terminal de contenedores, se tengan en cuenta las tendencias actuales en la flota.

De acuerdo con lo descrito en párrafos anteriores, en cuanto a la flota de buques portacontenedores, se mencionan 3 buques tipo de gran relevancia que permitirán valorar el más adecuado:

- Maxi Neo-Panamax [369 x 51.2 x 15], buque de mayores dimensiones que ha pasado por las nuevas esclusas de Panamá, cargando hasta 14.500 TEU's.

- Nuevos Clase E [E = 398 m, Manga = 56 m y Calado = 15.5 m], buques con hasta 21.000 TEU's de capacidad.

- Megamax 24 (MGX24), [E = 400 m, Manga = 61.5 y Calado = 16.5 m (max = 17.7 m)[10]], buques con hasta 24.000 TEU's de capacidad.

6.1.2 Factores que Condicionan la Configuración de una Terminal Especializada de Contenedores.

Uno de los aspectos relevantes en la planificación, gestión y capacidad de una Terminal Especializada de Contenedores (TEC), es la configuración del patio de almacenamiento. Por un lado, cuanto más compacta sea la terminal menor será el recorrido medio realizado por los equipos. Sin embargo, la escasez de espacio obliga a un aumento de la altura de apilado, incrementándose el número de movimientos y consecuentemente unas operaciones poco eficientes y reducción de los rendimientos.

Por otro lado, la configuración del patio de una TEC depende y está condicionada principalmente por la elección del equipo principal de almacenamiento, obteniéndose diferentes densidades de almacenamiento en función de la tipología de equipos. La determinación del espacio mínimo necesario en cada TEC está directamente relacionada con el cálculo de su capacidad y, depende de factores tales como la densidad superficial del equipamiento empleado, la altura de apilado, el tiempo medio de permanencia de un contenedor en patio y el volumen de tráfico.

[10] Dimensiones tomadas del portacontenedores Ever Alot tipo ULCS (Ultra Large Container Ship), construido en 2022.

Figura 6.12 Configuración y Capacidad Estática del Patio en Función del Equipo.

Nota: (1) El straddle carrier (carretilla pórtico) es un vehículo autopropulsado esencial en terminales de contenedores, diseñado para elevar, transportar y apilar contenedores ISO hasta en 4 alturas. A horcajadas, mueve cargas de hasta 60 toneladas, agilizando el flujo entre grúas pórtico (STS) y el almacenamiento en patio sin necesitar equipos adicionales.

(2) Las grúas RTG (Rubber Tyred Gantry o grúas pórtico sobre neumáticos) son equipos autopropulsados esenciales en terminales de contenedores para apilar, organizar y manipular contenedores en el patio de almacenamiento. Funcionan moviéndose sobre ruedas de caucho para estibar contenedores (usualmente 6 filas de ancho y 5-6 de alto) y cargarlos/descargarlos de camiones o tractores.

(3) Las grúas RMG (Rail Mounted Gantry) y ASC (Automated Stacking Cranes) son equipos esenciales de alto rendimiento para el apilamiento y movimiento de contenedores en terminales portuarias modernas, operando sobre rieles para maximizar la densidad de almacenamiento y eficiencia. Las RMG se usan principalmente para transferencia intermodal, mientras que las ASC son unidades automatizadas (frecuentemente sin operario) para el manejo rápido de contenedores de patio.

Fuente: Elaboración propia, 2026.

Además, existen múltiples posibilidades a la hora de establecer la configuración del patio de una TEC en función de la disposición de las pilas en planta, anchos y disposición de los pasillos y vialidades, configuración de las pilas, distancias entre ellas, bloques y contenedores, agrupación de los tráficos en función de sus orígenes/destinos, sentido de circulación, geometría del patio de la terminal, entre otros.

La búsqueda de la optimización del uso del espacio en la terminal está motivada por varios factores: económicos, productivos (capacidad) y energéticos. Por un lado, el costo de la utilización del suelo (tasa de ocupación) es proporcional a su tamaño. Por otro lado, se debe buscar la maximización de la capacidad del patio a través de la optimización de la altura de apilado (en función del equipo empleado), minimizando las remociones.

Desde el punto de vista de la eficiencia energética la disminución de la superficie de almacenamiento de la terminal reduce los recorridos tanto de los equipos de almacenamiento como de los vehículos de transporte horizontal que interconectan el patio de la terminal con el muelle. La minimización de dichos recorridos supone la

reducción del tiempo de ciclo de carga/descarga y de las demás operativas, lo que conlleva el aumento de la eficiencia, y un importante ahorro de combustible. Este segundo aspecto además de generar beneficios económicos para la terminal es también beneficioso en términos ambientales debido a la reducción de las emisiones de CO_2.

La determinación óptima de la configuración del patio una TEC puede llegar a representar para la misma un incremento de la capacidad de almacenamiento de hasta el 25% y llegar a reducir el costo por movimiento de contenedor en un 5%.

En definitiva, algunas de las cuestiones de importancia en cuanto a la optimización del uso del patio y su influencia en la mejora de la eficiencia son:

- Elección del equipamiento de almacenamiento en función de la tipología y volumen de tráfico.
- Orientación de las pilas de contenedores en planta en función del equipo utilizado.
- Ancho y disposición de pasillos y vialidades en la zona de almacenamiento.
- Posicionamiento de los equipos.
- Configuración de las pilas de contenedores.
- Sentido de circulación de las vialidades.

A continuación, se presentan algunas medidas relacionadas con estos aspectos para lograr una mejor optimización del uso del patio de una TEC.

6.1.2.1 Organización de las Zonas de Almacenamiento de Contendores

1. Orientación de las Zonas de Almacenamiento de Contenedores.

La organización de las zonas de almacenamiento en una terminal marítima especializada en contenedores responde a criterios operativos, logísticos, estructurales y de seguridad que buscan maximizar la productividad, minimizar movimientos improductivos y garantizar trazabilidad y control en tiempo real. El ordenamiento no es únicamente geométrico, sino funcional, y se diseña a partir del flujo físico del contenedor desde el muelle hasta la salida terrestre o viceversa.

El primer criterio fundamental es la proximidad operativa al frente de atraque. Los patios deben disponerse de manera que los bloques destinados a contenedores de importación y exportación estén estratégicamente ubicados respecto a las grúas de muelle y a las zonas de transferencia horizontal. En terminales modernas, el área inmediatamente posterior al muelle suele destinarse a zonas de transferencia o buffers operativos donde se produce el intercambio entre grúas de muelle y equipos de patio. Reducir distancias horizontales disminuye tiempos de ciclo y consumo energético, y aumenta la productividad por hora de grúa.

Un segundo criterio es la segregación por tipo de operación. Los contenedores de importación, exportación, transbordo y vacíos presentan patrones de permanencia y rotación distintos. Los de importación suelen permanecer más tiempo en patio y requieren accesibilidad frecuente desde el lado terrestre, mientras que los de exportación deben ordenarse en función del plan de estiba del buque, siguiendo una lógica de pre-stacking que facilite la secuencia de carga. El transbordo requiere proximidad tanto al muelle como a áreas de alta rotación, ya que su permanencia suele ser corta. Los contenedores vacíos pueden ubicarse en zonas más periféricas debido a su menor urgencia operativa.

El tercer criterio es la organización en bloques modulares. Los patios se estructuran en bloques rectangulares alineados paralelamente al muelle o a los ejes principales de circulación. Cada bloque se subdivide en bahías, filas y niveles de apilamiento. Esta organización permite que el sistema de gestión de terminal (TOS) asigne posiciones optimizadas en función de destino, peso, tipo de contenedor y ventana de salida. La modulación facilita expansión futura y mantenimiento sin interrumpir toda la operación.

Tabla 6.2 Ventajas y Desventajas de la Orientación de las Pilas en Función del Equipo.

Equipo	Paralelas al Muelle 	Perpendiculares al Muelle 
Straddle Carrier (SC)	Mayores recorridos promedio de los equipos.	Reduce las distancias de recorridos promedio de los equipos.
Rubber Tyred Gantry (RTG)	Necesidad de menos espacio en la zona de muelle. Las maniobras de los RTG's no interfieren en el funcionamiento de la operación marítima.	Necesidad de mucho espacio en la zona de muelle para maniobras de los RTG's. La maniobra de los RTG's en la zona de muelle dificulta la circulación de los vehículos. Reduce las distancias de recorridos promedio de los equipos.
Rail Mounted Gantry (RMG)	Mayores recorridos de los elementos de transporte horizontal. Zonas de almacenamiento demasiado largas, por lo que se hace necesario separarlas con vialidades aumentando así la superficie de almacenamiento y las distancias a recorrer por los equipos. Problemática en la circulación de los vehículos entre las zonas de almacenamiento.	Reduce las distancias de recorridos de los equipos, los vehículos de transporte horizontal dejan los contenedores en las cabeceras de las zonas de almacenamiento. Zona operativa, tanto marítima como terrestre, sin necesidad de vialidades de separación, para ello las zonas de almacenamiento no deben medir más de 300 – 400 m de longitud. No requieren vialidades entre las zonas de almacenamiento para los vehículos de transporte vertical.

Fuente: Elaboración propia, 2026

En relación con la orientación de las zonas de almacenamiento respecto al muelle, existen dos posibilidades de diseño del arreglo del patio de una TEC, con las zonas de almacenamiento paralelas o perpendiculares al muelle. Este factor está condicionado por la geometría de la terminal y por el equipo de almacenamiento empleado. En función de éste es más aconsejable orientar las pilas de la TEC de una forma u otra para que se pueda optimizar la superficie de esta.

Otro criterio esencial es la jerarquización de flujos internos. Las vialidades principales deben permitir circulación continua de equipos como RTG, RMG, straddle carriers o vehículos automatizados, evitando cruces innecesarios entre tráfico de muelle y tráfico terrestre. El diseño del patio debe minimizar interferencias entre flujos longitudinales y transversales, garantizando seguridad y eficiencia. En terminales de alta capacidad, la separación física entre flujos de equipo pesado y vehículos externos mejora significativamente el desempeño operativo.

La especialización por características del contenedor también condiciona la zonificación. Los contenedores refrigerados requieren áreas específicas equipadas con infraestructura eléctrica y sistemas de monitoreo, por lo que su ubicación debe considerar acceso técnico y redundancia energética. Los contenedores peligrosos deben almacenarse en zonas segregadas conforme a normativas internacionales, con distancias de seguridad y planes de contingencia específicos. Asimismo, cargas sobredimensionadas o especiales requieren superficies reforzadas y espacios de maniobra adicionales.

El criterio estructural del suelo es igualmente determinante. Las zonas con mayor densidad de apilamiento deben diseñarse sobre plataformas con mayor capacidad portante y menor deformabilidad, considerando que los esfuerzos transmitidos al terreno aumentan significativamente con alturas de apilamiento superiores a cuatro o cinco niveles. La geotecnia condiciona la distribución de cargas y puede influir en la localización de bloques de mayor rotación.

Desde la perspectiva de planificación dinámica, el ordenamiento del patio también responde a criterios temporales. Los contenedores se organizan en función de ventanas de arribo y salida, aplicando estrategias como segregación por buque, por puerto destino o por prioridad logística. Esto permite reducir reacomodos y movimientos improductivos, que son uno de los principales factores de ineficiencia en terminales de contenedores.

Finalmente, el diseño debe considerar la integración tecnológica. La automatización creciente en terminales modernas exige geometrías compatibles con grúas pórtico automatizadas, sistemas guiados o patios con control remoto. La disposición ordenada y repetitiva de bloques facilita implementación de sensores, sistemas de posicionamiento y control centralizado.

2. Disposición de las Vialidades y Posicionamiento de los Equipos.

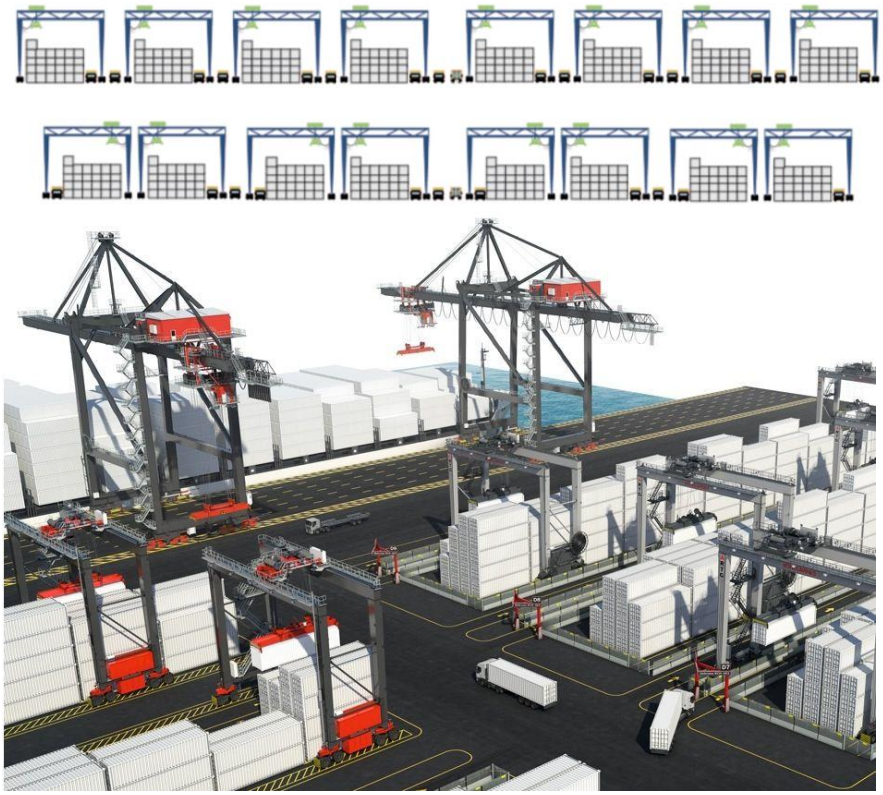
Otra cuestión a tener en cuenta para la optimización del espacio, además de la orientación de las pilas, es la disposición de los viales y el posicionamiento de los equipos.

En el caso de las terminales que utilizan RTGs como equipos de almacenamiento se consideran dos posibles arreglos:

- Un carril de circulación entre cada pila, estando las grúas RTG posicionadas de forma que el carril de circulación bajo pórtico está siempre del mismo lado (por ejemplo, lado tierra con relación a la zona de almacenamiento).

- Un único carril de circulación cada dos pilas, estando las grúas RTG posicionadas de forma contraria en cada una de ellas (por ejemplo, uno con el carril de circulación bajo pórtico del lado tierra y el otro del lado mar).

Figura 6.13 Disposición de las RTG's y de las Vialidades de Circulación.



Fuente: Elaboración propia, 2026

Considerando el mismo ancho de carriles en ambos casos, en la primera opción se necesitaría más superficie de zona de almacenamiento. Ambas configuraciones presentan ventajas y desventajas.

Tabla 6.3 Comparativa Entre Distintos Arreglos de Terminales con Grúas RTG.

	
Todas las zonas de almacenamiento van necesariamente separadas por un carril de circulación, más el espacio para la circulación de las RTG's. **Necesidad de menos espacio en la cabecera de las zonas de almacenamiento, el equipo se desplaza lateralmente para cambiar de una zona de almacenamiento a otra.** **Mejor accesibilidad a los contenedores almacenados por otro tipo de equipamiento, por ejemplo, Reach Stacker.**	**Otimiza más el espacio por reducir el número de carriles de las vialidades.** **Se necesita más espacio en la cabecera de las zonas de almacenamiento para que el equipo pueda cambiar de zona de almacenamiento (giro de 180°).** **Dificultad para acceder a los contenedores que estén ubicados entre dos zonas de almacenamiento que no tengan carril de separación entre ellas mediante otro equipo que no sea una grúa RTG.**

Fuente: Elaboración propia, 2026

3. Agrupación de los Tráficos

Normalmente, en la gestión del patio de almacenamiento se definen distintas áreas de agrupación de tráficos: zonas diferenciadas para los contenedores de importación, exportación y transbordo, contenedores vacíos, contenedores de 20' y 40', contenedores con mercancías peligrosas, contenedores especiales (sobredimensionados, reefers, etc.), carga y descarga del ferrocarril, etc. Además, en el caso de las grandes terminales, en cada una de estas áreas pueden reservarse espacios para grandes clientes y determinados servicios (líneas). Todos estos condicionantes minimizan la optimización del uso del patio, aumentando la superficie de almacenamiento y, por consiguiente, incrementando los recorridos medios tanto de los equipos de almacenamiento como de los de interconexión.

La mejor opción en este caso es la adopción del régimen caótico de almacenamiento, donde el TOS de la terminal es el que asignaría el "mejor" posicionamiento de los contenedores sin una previa planificación por parte del personal de la terminal. Es decir, en este caso no habría (o habría muy poca) agrupación de tráficos.

De acuerdo con lo anterior, en función de la geometría de la terminal (si esta es un condicionante) y del equipamiento de almacenamiento utilizado se debería estudiar con detenimiento cual será, en cada caso, la orientación de las zonas de almacenamiento, la disposición de los carriles viales, así como los anchos de estos, el posicionamiento de los equipos y la agrupación de los tráficos que mejor optimice la superficie de la terminal.

En resumen, el ordenamiento de zonas de almacenamiento en una terminal especializada de contenedores se fundamenta en la optimización de flujos, la segregación funcional por tipo de operación y carga, la modulación estructural del patio, la compatibilidad con equipos de manejo y la adaptación a criterios de seguridad y regulación. Cuando estos elementos se integran coherentemente, la terminal maximiza productividad por hectárea, reduce tiempos de ciclo y mejora su competitividad en el sistema portuario regional.

6.1.3 Otros Factores Condicionantes.

Los principales factores que condicionan la planeación de la ampliación del puerto en la laguna de Cuyutlán son, por una parte, la calidad del terreno y el medio físico donde se llevaran a cabo. A ello se le añaden otros factores que en un momento dado pueden resultar claves como, la proximidad de zonas urbanas, las regulaciones ambientales, determinadas circunstancias asociadas al tráfico marítimo, etc. Analizando estos factores, tenemos lo siguiente:

a. Características del desarrollo portuario.

Los condicionantes impuestos por el desarrollo portuario son de gran importancia y conviene dedicarles un estudio preliminar. Dentro de estas características, hay que tener en cuenta, al menos, las siguientes:

- **Las condiciones físicas de la zona**: Entre las condicionantes físicos está, en primer lugar, el clima marítimo del emplazamiento (el oleaje, las corrientes, mareas, etc.) y, en segundo lugar, los factores meteorológicos (los vientos reinantes, la posibilidad de precipitaciones torrenciales que provoquen avenidas o desbordamientos, las nieblas) y por último las condiciones físicas del terreno (dimensiones, profundidad, rellenos, etc.).

- **La naturaleza de los terrenos**: Los tipos de suelo a los que se puede encontrar en la naturaleza. Por lo tanto, nos encontramos con una amplia variedad de suelos en cuanto a composición, estructura, dureza, densidad, granulometría, etc. Es fundamental un conocimiento perfecto de los suelos en la zona de desarrollo ya que esto repercutirá sobre el diseño.

- **La proximidad a zonas habitadas**: La proximidad a zonas habitadas suele influir negativamente en el desarrollo de la infraestructura. De hecho, puede ser un impedimento para la realización de los trabajos por los inconvenientes que suponen para la población (malos olores, ruidos, etc.).

b. Condicionantes ambientales.

Un análisis medioambiental de la zona de desarrollo y el impacto que este tipo de obras tendrá en los ecosistemas de la zona, será una condición importante por tomar en cuenta, ya que, cada vez es un condicionante de mayor peso por la exigencia de la sociedad en su conjunto de respeto al medio natural.

6.1.3.1 Características de los Suelos.

Las obras de dragado son normalmente complejas y caras. Muchas veces constituyen el componente económico principal de las obras marítimas. Para poder proyectar de forma adecuada las obras de dragado se requiere un buen conocimiento del material a dragar y de los condicionantes ambientales.

De acuerdo con el estudio de mecánica de suelos desarrollado, la estratigrafía encontrada en la zona de proyecto permite reconocer tres formaciones principales, la más superficial está conformada generalmente por depósitos arcillosos de consistencia errática, muy blanda a muy firme, que se prolonga a una profundidad que oscila entre -3.5 y -5.5 m.

Le siguen suelos arenosos mayormente medianamente compactos que se extienden a una profundidad que varía entre -5.5 y -8.8 m. Finalmente aparece el Estrato Resistente constituido por arenas muy compactas, dando lugar incluso a reconocerlos como geomateriales, con algunos estratos compactos no continuos, que se prolonga hasta el final de los sondeos, o sea más allá de -31 m.

Las características de las tres formaciones principales encontradas se describen a continuación.

Formación 1:	Suelos arcillosos de resistencia errática: muy blanda a muy firme
horizonte superior:	nivel del fondo actual, entre -0.3 y -2.8 m
horizonte inferior:	entre -3.5 y -5.8 m
espesor:	entre 3.2 y 5.30 m
material:	Arcilla o arcilla muy poco arenosa (CH) color café gris, gris o gris oscuro, con vestigios de concha. Su consistencia es errática ya que va de muy blanda a muy firme.

Formación 2:	Suelos arenosos medianamente compactos
horizonte superior:	entre -3.5 y -5.8 m
horizonte inferior:	entre -5.5 y -8.8 m
espesor:	entre 1.2 a 5.0 m
material:	Arena mal graduada (SP, SP-SM), mayormente en estado medianamente compacto con estratos sueltos a compactos no continuos, color café gris, gris o gris oscuro, con poca pedacería de concha.

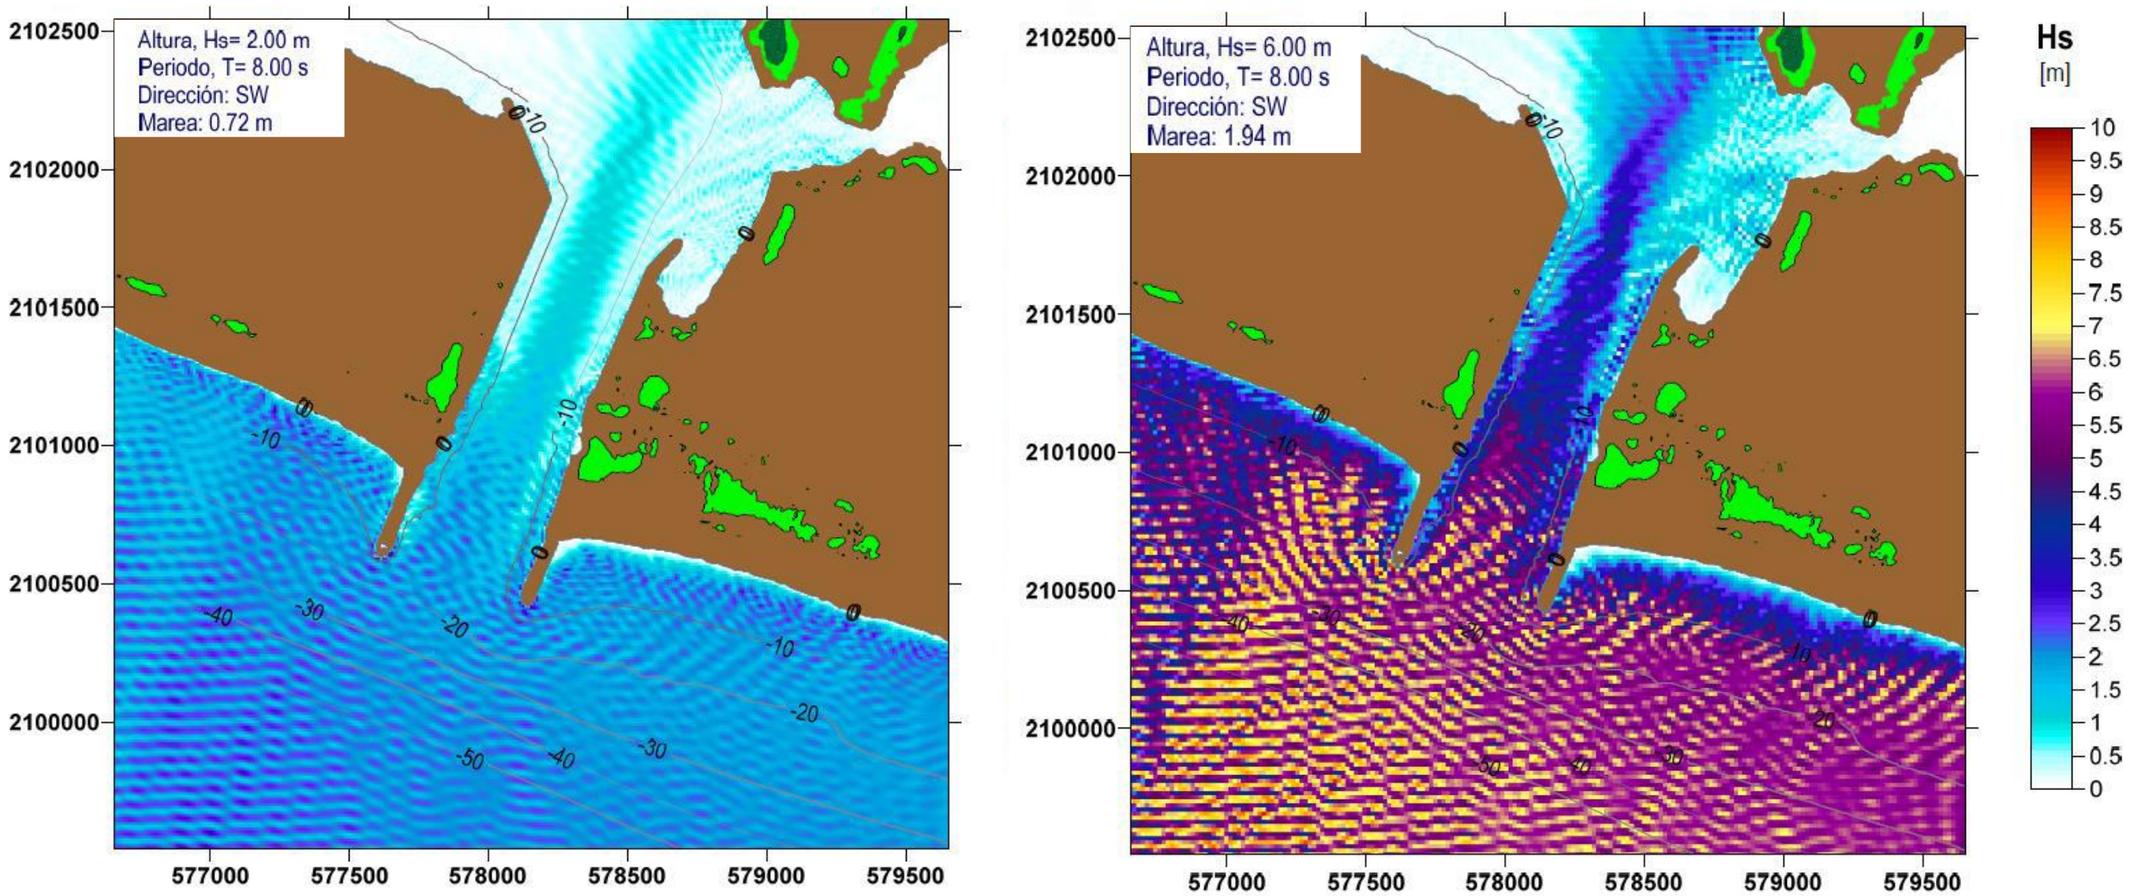
Formación 3:	Arena muy compacta (geomaterial)
horizonte superior:	entre -5.5 y -8.8 m
horizonte inferior:	más allá de -30.9 m
espesor:	mayor de 23 m
material:	Asociado al Estrato Resistente se encuentran arenas mal graduadas (SP, SP-SM) color café gris, gris claro o gris oscuro, en estado muy compacto (geomaterial), con algunos estratos compactos no continuos, con poca pedacería de concha.

6.1.3.2 Características Físicas de la Zona de Proyecto.

Se ha analizado la caracterización del oleaje y las corrientes en la Laguna de Cuyutlán, la escasa profundidad actual de la Laguna de Cuyutlán supone que el oleaje se encuentre limitado por fondo en la mayor parte de esta, de forma que las alturas de ola no son representativas de las esperadas en el futuro una vez se altere esta condición de profundidad. Sin embargo, la disipación del oleaje a su paso por el canal de Tepalcates sí permite establecer una primera valoración sobre el oleaje que penetra en el interior de la Laguna y que además podría ser considerado como un comportamiento hacia el interior de esta.

Como se aprecia en la Figura 6.4, en el escenario de clima medio se produce una disipación del 70% de la energía del oleaje a lo largo del canal, mientras que en el escenario de tormenta (correspondiente a la simulación del Huracán Patricia) la disipación es del 50%. Esta atenuación supone que en el caso de clima medio las alturas de ola significante en la dársena de ciaboga principal sean inferiores a 0.50 metros por lo que no limitarían las operaciones hacia el interior de la Laguna de Cuyutlán. En el caso extremal la altura de ola significante en la dársena de ciaboga supera los 3 metros, lo que sí podría tener un cierto impacto en las alternativas con terminales en el norte de la Laguna.

Figura 6.14 Propagación de Olaje en el Canal de Acceso en la Laguna de Cuyutlán.



Fuente: Proyecto Ejecutivo de Dragado del Muelle para el Manejo de Combustibles en la Laguna de Cuyutlán, en Manzanillo Colima, Logística de Fluidos y Graneles S.A. de C.V., 2019

En cuanto a las corrientes, existen corrientes de cierta intensidad en la margen noreste de la Laguna bajo condiciones de clima medio, en la boca de comunicación del Vaso II y III, pero esta situación no condicionaría las operaciones de entrada o salida de los buques ya que sus intensidades disminuyen rápidamente hacia el centro del Vaso II donde se encontrarían los canales de navegación. Bajo el escenario de tormenta las magnitudes fueron bastante elevadas en la zona del puente, pero igualmente los valores se atenúan hacia el centro de la Laguna y cabe recordar que el huracán ocurrió al inicio de un periodo de mareas vivas incrementando la cantidad de agua que entró al sistema lagunar.

Dadas las particularidades comentadas, se recalca la necesidad de confirmar los patrones de oleaje y de corrientes esperables mediante modelaciones una vez seleccionada la configuración conceptual de la ampliación del puerto en el interior de la Laguna de Cuyutlán para verificar los impactos reales en el diseño y las operaciones futuras. Dicho estudio será realizado por personal de la Universidad Nacional Autónoma de México (UNAM).

6.2 Áreas de Navegación.

El desarrollo portuario en la Laguna de Cuyutlán con su disposición en planta y de los canales de acceso, áreas de maniobra y dársenas, deben garantizar unas condiciones de operatividad y seguridad mínimas.

La definición correcta de un área de navegación o fondeo precisa la determinación de los elementos siguientes:

- La configuración geométrica de los espacios de agua y terrestres utilizados, mediante las definiciones precisas en planta y alzado de ejes, alineaciones, curvas, cotas, niveles y cuantos elementos sean necesarios para una determinación inequívoca de tales espacios.

- El balizamiento de señalización marítima que se prevea instalar para la identificación «in situ» de tales espacios, cuya definición deberá ser especialmente concreta en el caso de que se haya afinado el dimensionamiento basándose en la precisión de determinadas ayudas a la navegación.

- Las condiciones climáticas marítimas y atmosféricas límites que permitan la utilización de las áreas de navegación o fondeo en condiciones normales de operación. Estas condiciones podrán ser diferentes según e tipo y dimensiones de los buques, los remolcadores disponibles, o en función de cualquier otra condición particular que se haya definido en cada caso.

- Los requerimientos básicos de remolque que se precise disponer para la utilización de las áreas de navegación o fondeo por determinados tipos de buque, asociados a las condiciones climáticas en que puedan desarrollarse estas maniobras en condiciones normales de operación.

Un área de navegación o fondeo no queda definida, por tanto, solamente por sus características geométricas y su balizamiento, sino también por sus condiciones operativas y por la necesidad o no de utilización de remolcadores u otras ayudas a la navegación, circunstancias que determinan, no sólo el que pueda disponerse de mayores o menores porcentajes de tiempo aptos para la operación de los buques, sino también las propias dimensiones de los espacios de agua requeridos.

Por tal motivo, el procedimiento recomendado para la definición de las áreas de navegación en el interior de la Laguna de Cuyutlán es el siguiente:

- Establecer las características de la flota de buques que operará en la zona en los diferentes años a futuro que vayan a considerarse dentro de la vida útil; en general se dispondrá de la siguiente flota atendiendo a las previsiones de tráfico.

  En este caso en particular, de acuerdo con lo descrito anteriormente, la flota de buques portacontenedores de diseño, se compone de 3 buques:

  – Maxi Neo-Panamax [Eslora = 369 m, Manga = 51.2 m y Calado = 15 m], buque de mayores dimensiones que ha pasado por las nuevas esclusas de Panamá, cargando hasta 14.500 TEU’s.

  – Nuevos Clase E [Eslora = 398 m, Manga = 56 m y Calado = 15.5 m], buques con hasta 21.000 TEU’s de capacidad.

  – Megamax 24 (MGX24), [Eslora = 400 m, Manga = 61.5 y Calado = 16.5 m (max = 17.7 m)], buques con hasta 24.000 TEU’s de capacidad.

  Siendo el buque MGX24, por sus dimensiones, el más relevante para el diseño de las áreas de navegación.

- Prefijar las condiciones climáticas marítimas y atmosféricas límites para las distintas maniobras de buques que puedan desarrollarse en la zona que se considere. Estas condiciones se muestran en la tabla 6.2.

Tabla 6.3 Condiciones Físicas.

Oleaje[1] (Dirección / Hs)	Viento Dirección / Velocidad)	Corriente Superficial	
		Exterior Dirección / Velocidad)	Interior (Velocidad)
SSW / 2.0 m	NNE – SE – SSW – WNW / 20 nudos	ESE – WNW / 2.0 nudos	0.50 nudos[2]

Nota: (1) Oleaje en el exterior del canal de acceso, en la zona de morros de las escolleras.
(2) Velocidad en la boca de comunicación entre el Vaso II y el Vaso III.
Fuente: Elaboración propia, 2026.

Considerando el clima local es posible establecer las condiciones climáticas para el dimensionamiento de las áreas de navegación.

De acuerdo con la información del viento y a las características del área de proyecto se consideran las siguientes direcciones de análisis:

– Por su alta frecuencia de presentación se consideran las direcciones NNE y WNW, donde la primera no tiene gran influencia en el acceso al puerto, debido a su alineamiento con el canal Tepalcates y su baja intensidad. La segunda complica la maniobra debido a su transversalidad al canal de acceso.

– Por su elevada intensidad se consideran las condiciones SE y SSW, donde la primera complica la maniobra debido a su dirección transversal y la segunda perjudica la parada del buque en la dársena de ciaboga, al incidir por popa en el canal de acceso.

Con base a la información del oleaje disponible, se considera un único escenario de referencia por su alta frecuencia de presentación, con oleaje SSW de 14 segundos de periodo (periodo de pico promedio), considerando una altura de ola significante de referencia de 2.0 m, debido a la complejidad que supone tanto para la conexión como para la operación de los remolcadores.

El nivel de agua no se considera un factor relevante para el estudio, por lo que, de forma genérica, se considera el valor del nivel de bajamar medio inferior como el nivel de referencia (NBMI, 0.0 m), que, además, reduce el resguardo bajo quilla, siendo por lo tanto una situación desfavorable para la navegación.

Según la conversación mantenida con los Prácticos locales se ha confirmado la siguiente información relativa a la corriente:

- Las corrientes son paralelas a la costa, en los dos sentidos, y completamente transversales al canal de acceso. No se ha podido determinar estacionalidad o dependencia en la dirección del oleaje con otros factores.

- La intensidad máxima de la corriente observada es de unos 2.5 nudos, y esta ocurre tras un fuerte temporal, y la mínima de unos 0.2 nudos. La velocidad de la corriente, de forma general, suele encontrarse en valores entre 0.5 nudos y 1.5 nudos.

- Una vez el buque ha superado los morros de las escolleras no se aprecia corriente.

- En ocasiones, la dirección de la corriente varía significativamente entre la recalada y el canal de acceso. Para conocer la corriente cerca del canal de acceso emplean una embarcación menor, dejándola derivar para determinar la corriente, ya que no se dispone de más información ni elementos de medida de la corriente, que se han solicitado en numerosas ocasiones.

En nuestro caso, la corriente de referencia en mar abierto (zona de morros en las escolleras del canal de acceso) es paralela a la costa, de componentes ESE y WNW que no penetra en el canal de acceso. Como velocidad de corriente superficial de referencia se considera 2 nudos en ambos casos.

En el interior de la laguna puede verse afectado por corrientes locales, debidas principalmente al flujo y reflujo de la marea entre los distintos vasos. En concreto, en la zona de estudio, y en épocas de lluvias, se produce una importante corriente de desagüe del Vaso III al Vaso II que se presenta en la zona de maniobra de la dársena de ciaboga No. I. Para la corriente en el interior de la Laguna de Cuyutlán se considera una corriente de 0.50 nudos, asociada al flujo y reflujo de la marea.

La definición geométrica de las Áreas de Navegación y maniobra está basada en el conocimiento de los espacios ocupados por los buques, que dependen de:

- El propio buque y los factores que afectan a sus movimientos.
- El nivel de las aguas y los factores que afectan a su variabilidad.

Para que la navegación se efectúe en condiciones de seguridad, estos espacios ocupados por el buque deberán tener cabida suficiente dentro de los espacios físicos disponibles en el emplazamiento, para lo cual será necesario tomar en consideración los factores de incertidumbre relacionados con el contorno (suelo, paramentos, otros buques navegando o en flotación, elementos que afecten a los gálibos, etc.). Con objeto de mantener un adecuado margen de seguridad, se precisa disponer de unos espacios adicionales entre los requeridos por los buques y los disponibles según las condiciones de contorno del emplazamiento.

Para la valoración de los resguardos de seguridad se toma en consideración los diferentes supuestos de riesgo que pueden presentarse atendiendo a la siguiente tipología de modos de fallo o estados límite últimos:

- Colisión entre embarcaciones en navegación.
- Colisión de una embarcación en navegación con un objeto flotante (embarcación fondeada o amarrada, boya, etc.).
- Impacto de un buque con un objeto fijo rígido (muelle, pila o tablero de un puente, etc.).
- Contacto de un buque con el fondo o taludes del suelo, tomando en cuenta la naturaleza de éste, así como la posibilidad de que se produzca una varada.

6.2.1 Determinación de Profundidades de Agua de Las Áreas de Navegación

Para la determinación de la profundidad de agua necesaria en las diferentes áreas de navegación (canal de acceso, dársenas de ciaboga, dársena de muelle y canales interiores), se realizó en cada caso tomando en consideración los factores siguientes:

- El calado de los buques y los factores relacionados con los barcos que puedan ocasionar que algún punto de su casco alcance una cota más baja que la correspondiente a quilla plana en condiciones estáticas en agua de mar.
- El nivel del agua que se considere y los factores que afectan a su variabilidad, que determinarán el plano de referencia para emplazar el buque.
- Los márgenes de seguridad que se establezcan para prevenir un contacto del buque con el fondo.

En general el análisis se efectuó suponiendo que los buques de diseño operarán a plena carga. Asimismo, se fijaron las condiciones climatológicas (mareas, vientos, oleajes, etc.) y de seguridad y ayudas a la navegación (resguardos, remolcadores, etc.), que permitiesen efectuar las operaciones requeridas en la ampliación del puerto en el interior de la Laguna de Cuyutlán.

6.2.2 Determinación de la Configuración y Dimensiones de las Áreas de Navegación.

La determinación de la configuración y dimensiones en planta necesarias en las diferentes áreas de navegación en el interior de la Laguna de Cuyutlán se tomó en cuenta las áreas planteadas en la planeación de la ampliación del puerto de Manzanillo en dicha laguna, para lo cual se realizó una revisión en cada caso tomando en consideración los factores siguientes:

- El tamaño, dimensiones y características de maniobrabilidad de los buques de diseño y los factores relacionados con los barcos, incluida la disponibilidad de remolcadores, de los que depende la superficie necesaria para la realización de la navegación,

maniobras o permanencia de los buques en el área que se considere (canal de acceso, dársenas de ciaboga, dársena de muelle y canales interiores).

- Las ayudas a la navegación disponibles y los factores que afectan a su exactitud y fiabilidad, que determinarán las líneas o puntos de referencia para emplazar el buque.

- Los márgenes de seguridad que se establezcan para prevenir un contacto del buque con los contornos de las áreas de navegación o flotación (a pie de muelle), o con otras embarcaciones u objetos fijos o flotantes que puedan existir en el entorno.

La consideración de los factores anteriores permite determinar la superficie y dimensiones mínimas requeridas en planta, o dimensiones nominales, que deberán ser exigidas a las profundidades nominales de agua en función de los buques de diseño.

6.2.3 Bocana del Canal de Acceso

La boca de entrada y salida de la Laguna de Cuyutlán se proyectó tomando en consideración los siguientes condicionantes principales:

- La configuración general de la ampliación del puerto y su integración con la infraestructura futura (muelles, dragados, etc.) y en sus áreas de flotación (canales de navegación, áreas de maniobras de buques, dársenas, etc.), así como la morfología y tipología estructural de los elementos que configuran la bocana.

- La navegación de entrada y salida de los buques a la ampliación del puerto, contemplando tanto las intensidades de tráfico previsibles, como los mayores buques de diseño que se prevea operen en el puerto, en las condiciones límites de operación que se establezcan.

- La limitación a la entrada de energía del oleaje en el interior de la ampliación del puerto, atendiendo al clima marítimo existente en el emplazamiento, de manera que la agitación que se produzca en las áreas de flotación utilizadas por el puerto sea la menor posible, en función de los usos que se prevea desarrollar en cada una de ellas.

- La conveniencia de limitar los períodos de cierre del puerto que se generen en la propia bocana, ocasionados por el clima marítimo existente en la zona y la configuración que se adopte para la bocana (rotura del oleaje en la boca del puerto, generación de fuertes corrientes transversales, etc.).

- La dinámica litoral existente en la zona y las modificaciones que se puedan producir en ella a consecuencia de las propias infraestructuras portuarias, tomando en consideración no sólo las afecciones que puedan producirse en el propio puerto

(aterramientos de la bocana y de otras áreas de navegación), sino también los que se pudieran ocasionar en otras zonas próximas o remotas afectadas por la misma dinámica litoral.

- Las características geológicas y geotécnicas en la zona de desarrollo y la idoneidad consecuente de los terrenos para recibir obras de infraestructuras o desarrollar sobre ellos áreas de flotación.

- Las previsibles ampliaciones del puerto y las limitaciones que a este respecto pudiera representar la configuración que se adopte para la bocana.

- Los impactos medioambientales que puedan producirse tanto en fase de construcción como en fase de servicio, etc.

- La incidencia de otros condicionantes de planificación diferentes estrictamente portuario, que pudieran afectar al desarrollo portuario en concreto que se analice, y en particular los que se deriven del planeamiento urbano y costero.

En la práctica, la consideración de todos estos condicionantes conducirá a soluciones en las que se consiga un equilibrio entre condicionantes que a veces resultarán contrapuestos (por ejemplo, la obtención de la mejor accesibilidad podría conllevar unos índices de agitación en el interior del puerto poco adecuados para el futuro desarrollo portuario en la Laguna de Cuyutlán).

6.2.4 Áreas de Maniobra

Cuando un barco se aproxima a un puerto o a una terminal, ya sea navegando desde el mar abierto o por una vía de navegación, debe hacerlo a una velocidad mínima suficiente para mantener la navegación controlada en función de las características del emplazamiento y de las condiciones climáticas existentes. Antes de que el buque efectúe las maniobras de atraque debe poder reducir su velocidad prácticamente a cero, necesitando un espacio suficiente para que esta parada del buque pueda desarrollarse en condiciones de seguridad. Por otra parte, y simultánea o posteriormente a la operación anterior, es necesario en un gran número de casos que el buque cambie su orientación, girando en espacios reducidos para adecuarse a la alineación requerida por el muelle o atraque que vaya a ocupar.

El proceso es similar en las maniobras de salida, pudiendo requerirse reviro de buques y aceleración de su movimiento para alcanzar las condiciones necesarias de navegación para abandonar el puerto en condiciones de seguridad. Los espacios necesarios para esta doble función de parada (o aceleración) y reviro del buque se engloban dentro del concepto de áreas de maniobra, ya que frecuentemente son operaciones interconectadas y que en ocasiones pueden desarrollarse en un mismo espacio

El dimensionamiento de las áreas de maniobra depende fundamentalmente de los aspectos siguientes:

- El tamaño, dimensiones y características de los buques más desfavorables que se prevé recibir (que pudieran no ser los mayores, por lo que habitualmente se precisará analizar diversos tipos de buques).

- El volumen y naturaleza del tráfico, así como las velocidades admisibles de navegación con que los buques acceden a estas áreas.

- Las características geométricas de los espacios en los que deben desarrollarse estas maniobras.

- El clima marítimo existente en la zona y en particular las condiciones límites de operación que se establezcan para la realización de las maniobras.

- Los efectos de caída lateral de la popa que se producen en las fases finales de la maniobra y que son más acusados en los buques de formas llenas, a bajas velocidades, y más acentuados cuanto más elevada es la profundidad de agua y cuanto mayor es el régimen de máquina atrás utilizado en la maniobra.

- La disponibilidad de remolcadores y las características de estos para la realización de las diferentes operaciones asociadas a la maniobra.

En el análisis realizado, se parte del hecho que no se efectúan maniobras de dos o más buques simultáneamente, por lo que las dimensiones que se establecen están basadas en los espacios requeridos para un solo buque.

6.2.5 Canales de Navegación.

El proyecto de un canal de navegación depende principalmente de los siguientes factores:

- El tamaño, dimensiones y características de maniobrabilidad de los buques más desfavorables que se prevé recibir (que pudieran no ser los mayores, por lo que habitualmente se precisará analizar diversos tipos de buques); en el supuesto de que el estudio se realice considerando la flota subdividida en tramos se considerará el más desfavorable de cada tramo.

- El volumen y naturaleza del tráfico, así como las velocidades admisibles de navegación.

- El tipo de navegación que se prevea realizar, en función del número de vías de circulación disponibles.

- Las características geométricas de la alineación de la vía navegable y las condiciones del entorno en que se encuentre situada.

- El tipo de las ayudas a la navegación, así como sus características de exactitud y disponibilidad.

- La profundidad y características geométricas transversales de la vía navegable.

- La estabilidad de los taludes de la vía navegable.

- Las condiciones climáticas marítimas y meteorológicas existentes en la zona, especialmente la naturaleza e intensidad de las corrientes transversales y muy destacadamente la variación de estas corrientes a lo largo del eje de la vía navegable.

- La experiencia de los pilotos de puerto.

Para la revisión de las áreas de navegación se partirá de la traza definida de las áreas de navegación, determinándose a continuación la anchura requerida en todas sus secciones críticas, para establecer posteriormente las transiciones de anchura entre los diferentes tramos. El procedimiento será iterativo en la medida en que la consideración de los diferentes factores obligue a reconsiderar alguno de los parámetros iniciales de diseño.

Aunque la revisión del trazado en planta de las áreas de navegación depende en gran medida de la definición de las condiciones locales, se han seguido las siguientes recomendaciones generales para la dicha revisión del diseño:

- El canal de navegación debe ser lo más recto posible, evitando trazados en S (curva seguida de contracurva).

- El canal de navegación deberá seguir, si es factible, la dirección de las corrientes principales, de manera que se minimice el efecto de las corrientes transversales. Este criterio también deberá seguirse con vientos y oleajes, si bien será más difícil de conseguir dado que normalmente provendrán de diversas direcciones. Asimismo, se debe evitar las áreas de depósito de sedimentos, para minimizar los costos de mantenimiento.

- El canal de navegación de aproximación se orientará si es factible, de manera que se eviten los temporales de través, es decir, orientándolas preferentemente en la

dirección del oleaje reinante o cuanto más formando ángulo de hasta 15/20° entre eje de la vía de navegación y la dirección de estos oleajes reinantes.

- El canal de navegación de aproximación a la bocana de la laguna debe ser preferentemente recto evitando curvas en o próximas a la entrada, de manera que se evite la necesidad de que los buques tengan que efectuar correcciones de rumbo en una zona difícil y crítica para la navegación.

- El trazado de los canales de navegación tratará de evitar que los barcos tengan que efectuar la aproximación a muelles y atraques transversalmente a ellos, lo que podría producir un accidente en caso de pérdida de control del buque. De ser posible el canal de navegación deberá quedar situado paralelo a muelles y atraques para que esta maniobra se efectúe con mínimo riesgo. Esta precaución se extremará en caso de tratarse de tráfico de mercancías peligrosas.

- El paso de secciones estrechas (puentes, bocanas, etc.) se efectuará en tramos rectos bien balizados de la vía navegable, manteniendo la alineación recta en una distancia mínima de 5 esloras del buque máximo, a uno y otro lado de la sección estrecha.

- En caso de precisarse curvas es mejor una sola curva que una secuencia de pequeñas curvas a cortos intervalos, siempre y cuando la vía navegable esté correctamente balizada.

- El radio de las curvas será como mínimo de 5 esloras del buque de mayores dimensiones que se prevé utilizará la vía navegable, utilizándose preferiblemente radios de 10 esloras o más si es factible; los valores mayores se utilizarán cuanto más grande sea el ángulo entre las alineaciones rectas que definen la curva.

- La longitud de los tramos curvos no debe ser mayor que la mitad del radio de la curva, lo que significa que el ángulo entre alineaciones rectas no debe ser superior a 30°, si es factible.

- La distancia de visibilidad medida en el eje de la vía de navegación debe ser superior a la distancia de parada del buque de diseño suponiendo que navega a la velocidad máxima de navegación admisible en la vía.

- Las transiciones entre tramos de diferente anchura se efectuarán ajustando las líneas límites o de limitación mediante alineaciones rectas con variaciones en planta no mayores de 1:10 (preferentemente 1:20) en cada una de ellas.

6.2.6 Revisión de las Áreas de Navegación

La revisión de las áreas de navegación en el interior de la Laguna de Cuyutlán considera la alternativa número tres planteada en el apartado No. 4.1, así como la consideración de las recomendaciones de diseño (Manual de Dimensionamiento Portuario, Recomendaciones de Obras Marítimas, recomendaciones emitidas por el PIANC, las normas BS, etc.) para las áreas de navegación.

De acuerdo con el análisis desarrollado para la revisión de las áreas de navegación se obtuvieron los resultados mostrados en la Tabla 6.4.

Tabla 6.4 Resumen de Resultados de Dimensiones de Áreas de Navegación.

Buque de Diseño				Ancho de Plantilla de Canal			Dársenas			
Tipo	Eslora (m)	Manga (m)	Calado (m)	Bocana (m)	Acceso (m)	Interno (m)	Ciaboga			Operativa en Muelles (m)
							No. I (m)	No. II (m)	No. III (m)	
Anteproyecto	–	–	–	300	300	200		800	600	146
New Panamax	370	45.80	17.70	234	138	138 a 182	600	800	800	138

Fuente: Elaboración propia, 2026.

La propuesta original planteada para el desarrollo portuario considera la ampliación de la plantilla del canal de acceso de 250 a 300 m de ancho y en el interior los canales de navegación. Considerando el análisis realizado, se tiene que para una embarcación de 400 m de eslora y una manga de 62 m y bajo las condiciones físicas existentes en la zona de proyecto, el ancho de la plantilla en la bocana del canal de acceso se requiere sea de 316 m, que resulta mayor de los 250 m que actualmente tiene, asimismo, el ancho de plantilla requerido en el resto del canal de acceso es de 224 m que resulta ser menor al existente. Por otra parte, para el caso de los canales interiores, el ancho de la plantilla de acceso se ha definido de 200 m siendo similar a lo planteado en el anteproyecto original.

Considerando lo anterior, se recomienda que el ancho de la plantilla del canal de acceso en la zona entre morros de la escollera se amplie a 316 m en una longitud de 270 m, posteriormente se tendría una transición para pasar de 316 m de ancho a 250 m, esta transición tendría una longitud de 450 m. El resto de la plantilla del canal de acceso sería de 250 m y con una longitud de 917.82 m, con lo cual, el canal de acceso tendría una longitud total de 1,637.82 m.

Por lo que respecta a las dársenas de ciaboga, el anteproyecto original contempla tres dársenas de ciaboga con diámetros de 600 m y 800 m. Considerando el análisis realizado y como se ha comentado anteriormente, la dársena existente o la dársena de ciaboga No. 1, mantiene su diámetro de 600 m de eslora para una primera etapa, ya que esta solo será utilizada por los buques gaseros de la empresa KMS y por los buquetanques de la empresa LFG. La dársena de ciaboga No. 2, que se localiza hacia el norte del canal de acceso, tendrá un diámetro de 800 m, la cual estará conectada con el canal de acceso por un canal de navegación de 250 m de ancho y con el canal interior de navegación Norte, el cual tendrá un ancho de 200 m.

La dársena de ciaboga No. 3, que se localiza en la zona noroeste del Vaso II de la laguna de Cuyutlán, el anteproyecto de planeación original contempla una dársena de ciaboga de 600 m de diámetro, sin embargo, considerando el análisis desarrollado esta dársena se propone con un diámetro de 800 m, similar a la dársena No. 2, lo anterior se fundamenta que esta zona en particular de la laguna, durante marea baja queda expuesto el fondo marino, lo anterior implica que la única zona profundizada sería la dársena de ciaboga y con las paredes a una distancia corta de la embarcación (100 m aproximadamente) podrían presentarse problemas de succión de la embarcación hacia las paredes de la dársena, asimismo, la visión que se tendría desde el puente de mando del buque sería deficiente por la altura del puente de mando con respecto a las orillas de la dársena.

Por último, los canales de navegación interna, se tendrá un canal localizado hacia el norte de la Laguna (canal de navegación norte), paralelo a los muelles de las terminales especializadas de contenedores, con un ancho de plantilla de 200 m, el cual conectará la dársena de ciaboga No 2 con la dársena de ciaboga No. 3. El segundo canal se localizará al sur de las islas cocodrilo (canal de navegación su), contará con un ancho de 200 m y conectará la dársena de ciaboga No. 3 con la dársena de ciaboga No. 2. En una primera etapa, el canal principal de navegación interna será el canal norte, esto es, que será este canal el que se use para entrar y salir del puerto, quedando el canal sur como un canal reservado para las embarcaciones de la Secretaría de Marina. Para una segunda etapa, el canal norte será utilizado solo de entrada, desde la bocana hasta la dársena de ciaboga No. 3 y el canal sur exclusivamente de salida, esto es, desde la dársena de ciaboga No. 3, hasta la bocana, lo anterior busca reducir los tiempos de maniobra de entradas y salidas del futuro puerto.

Las profundidades de dragado de las áreas de navegación definidas anteriormente se realizó el análisis correspondiente cuyos resultados se muestran en la Tabla 6.5. En la primera etapa de desarrollo, la profundidad de la bocana en el canal de acceso se tendrá una profundidad de -19.00 m y en el resto de las áreas de navegación interna se tendrá una profundidad de -18.00 m, solo en el canal de navegación sur la profundidad será de -10.00 m. Para la segunda etapa, la bocana tendrá una profundidad de -22.50 m y el resto de las áreas de navegación se profundizará a -21.00 m, incluyendo el canal de navegación sur.

Todas las profundidades están referidas al Nivel de Bajamar Media Inferior (NBMI).

Tabla 6.5 Resumen de Resultados de Análisis de Profundidad de Áreas de Navegación.

Buque de Diseño				Profundidad en Plantilla de Canales			Dársenas			
							Ciaboga			Operativa en Muelles (m)

Fuente: Elaboración propia, 2026.

En resumen, las áreas de navegación quedan definidas de la siguiente forma:

I. Primera Etapa.

a. Canal de Acceso:

1. Bocana:

- Ancho: 316 m
- Largo: 270 m
- Profundidad de dragado: -19.00 m
- Talud de dragado: 4:1 (H:V)

2. Canal de Acceso Transición:

- Ancho: 316 m a 250 m
- Largo: 450 m
- Profundidad de dragado: de -19.00 m a -18.00 m
- Talud de dragado: 4:1 (H:V)

3. Canal de Acceso:

- Ancho: 250 m
- Largo: 917.82 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 4:1 (H:V)

La longitud total del canal de acceso es 1,637.82 m

b. Canal Interior:

1. Zona entre Dársenas 1 y 2:

- Ancho: 250 m
- Largo: 1,932.95 m
  - Curva No. 1:
    - Ancho: 250 m
    - Largo: 519.58 m
    - Radio: 800 m
  - Tramo Recto:
    - Ancho: 250 m
    - Largo: 1,153.10 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 260.27 m
    - Radio: 1,200 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

2. Zona entre Dársenas 2 y 3 (Canal Norte):

- Ancho: 200 m
- Largo: 4,178.58 m
  - Curva No. 1:
    - Ancho: 200 m
    - Largo: 652.00 m
    - Radio: 1,200 m
  - Curva No. 2:
    - Ancho: 200 m
    - Largo: 1,134.68 m
    - Radio: 1,200 m
  - Tramo Recto No. 1:
    - Ancho: 200 m
    - Largo: 1,561.96 m
  - Tramo Recto No. 2:
    - Ancho: 200 m
    - Largo: 829.94 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) arenas y 6:1 (H:V) arcillas

c. Canal Sur:

1. Zona entre Dársenas 3 y 2:

- Ancho: 200 m

- Largo: 3,983.25 m
  - Tramo Recto No. 1:
    - Ancho: 200 m
    - Largo: 1,032.77 m
  - Curva No. 1:
    - Ancho: 200 m
    - Largo: 399.14 m
    - Radio: 1,100 m
  - Tramo Recto No. 2:
    - Ancho: 200 m
    - Largo: 1,355.24 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 210.63 m
    - Radio: 1,100 m
  - Tramo Recto No. 3:
    - Ancho: 200 m
    - Largo: 985.47 m
- Profundidad de dragado: -10.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

Las tres dársenas de ciaboga presentan las siguientes características:

d. Dársena de Ciaboga No. 1:

- Diámetro: 600 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

e. Dársena de Ciaboga No. 2:

- Diámetro: 800 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

f. Dársena de Ciaboga No. 3:

- Diámetro: 800 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

II. Segunda Etapa.

a. Canal de Acceso:

1. Bocana:

- Ancho: 316 m
- Largo: 270 m
- Profundidad de dragado: -22.50 m
- Talud de dragado: 4:1 (H:V)

2. Canal de Acceso Transición:

- Ancho: 316 m a 250 m
- Largo: 450 m
- Profundidad de dragado: de -22.50 m a -21.00 m
- Talud de dragado: 4:1 (H:V)

3. Canal de Acceso:

- Ancho: 250 m
- Largo: 917.82 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 4:1 (H:V)

La longitud total del canal de acceso es 1,637.82 m

b. Canal Interior:

1. Zona entre Dársenas 1 y 2:

- Ancho: 250 m
- Largo: 1,932.95 m
  - Curva No. 1:
    - Ancho: 250 m
    - Largo: 519.58 m
    - Radio: 800 m
  - Tramo Recto:
    - Ancho: 250 m
    - Largo: 1,153.10 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 260.27 m
    - Radio: 1,200 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

2. **Zona entre Dársenas 2 y 3 (Canal Norte):**
   - Ancho: 200 m
   - Largo: 4,178.58 m
     - Curva No. 1:
       - Ancho: 200 m
       - Largo: 652.00 m
       - Radio: 1,200 m
     - Curva No. 2:
       - Ancho: 200 m
       - Largo: 1,134.68 m
       - Radio: 1,200 m
     - Tramo Recto No. 1:
       - Ancho: 200 m
       - Largo: 1,561.96 m
     - Tramo Recto No. 2:
       - Ancho: 200 m
       - Largo: 829.94 m
   - Profundidad de dragado: -21.00 m
   - Talud de dragado: 3:1 (H:V) arenas y 6:1 (H:V) arcillas

c. **Canal Sur:**

1. **Zona entre Dársenas 3 y 2:**
   - Ancho: 200 m
   - Largo: 3,983.25 m
     - Tramo Recto No. 1:
       - Ancho: 200 m
       - Largo: 1,032.77 m
     - Curva No. 1:
       - Ancho: 200 m
       - Largo: 399.14 m
       - Radio: 1,100 m
     - Tramo Recto No. 2:
       - Ancho: 200 m
       - Largo: 1,355.24 m
     - Curva No. 2:
       - Ancho: 250 m
       - Largo: 210.63 m
       - Radio: 1,100 m
     - Tramo Recto No. 3:
       - Ancho: 200 m
       - Largo: 985.47 m
   - Profundidad de dragado: -21.00 m

- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

Las tres dársenas de ciaboga presentan las siguientes características:

d. Dársena de Ciaboga No. 1:

- Diámetro: 600 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

e. Dársena de Ciaboga No. 2:

- Diámetro: 800 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

f. Dársena de Ciaboga No. 3:

- Diámetro: 800 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

La superficie total navegable o de las zonas de navegación interior de la Laguna de Cuyutlán es de 372.35 ha[11].

6.3 Propuesta de Desarrollo.

Considerando el análisis de las tres alternativas, se ha seleccionado la alternativa No. 3 para el desarrollo portuario en la Laguna de Cuyutlán, la cual se describe a continuación.

La ampliación del puerto de Manzanillo en la laguna de Cuyutlán será desarrollada en dos etapas, la primera de ellas tendrá una superficie total de 270.04 ha, ver Tabla 6.6. Del total de esta superficie el 68% esta destinada al desarrollo de las dos terminales especializadas de contenedores, lo que representa 184.57 ha. El 9% (24.71 ha) corresponde a la zona del estacionamiento para trailers.

Las vialidades externas a la plataforma donde serán desarrolladas las terminales representan el 8% (20.35 ha) de la superficie total de la primera etapa, por lo que respecta al área destinada para la localización de la zona administrativa y de servicios, ocupa el 10% (26.40 ha) de la superficie total. Por último, el restante 5% (14.32 ha) corresponde a las cuatro líneas de ferrocarril.

[11] La supercie no incluye la zona dragada de localización de las plataformas.

Tabla 6.6 Distribución de Superficie en la Primera y Segunda Etapa de Desarrollo.

Zona			Superficie (ha)
Etapa 1	Plataforma	TEC I	95.00
		TEC II	82.15
		Vialidades	7.42
		Subtotal	**184.57**
	Zona Administrativa		13.13
	UNAPROP		13.28
	Estacionamiento		24.71
	Vialidades[(1)]	Superficial	9.36
		elevada	10.99
		Subtotal	**20.35**
	Ferrocarril	Superficial	5.13
		elevada	9.18
		Subtotal	**14.32**
	Total		**270.36**
Etapa 2	Plataforma	TEC III	63.12
		TEC IV	82.15
		TEC V	15.00
		Subtotal	**160.27**
	Vialidades	Superficial	39.67
		elevada	3.54
		Subtotal	**43.22**
	Ferrocarril[(2)]		36.03
	Torres CFE		101.81
	Total		**341.33**
TOTAL			**611.69**

Nota: (1) Solo se considera el área de vialidades externas a la superficie de la plataforma para la localización de las dos terminales especializadas de contenedores.
(2) Todas las líneas de ferrocarril de la segunda etapa son superficiales.

Fuente: Elaboración propia, 2026.

En la segunda etapa de la ampliación del puerto, tiene una superficie total de 341.33 ha, las cuales se distribuyen de la siguiente forma, el 47% está destinada al desarrollo de las tres terminales especializadas (dos de contenedores y una TUM o terminal de Cabotaje), lo que representa 160.27 ha. El 30% (101.81ha) corresponde a la zona destinada para la reubicación de las torres de alta tensión de la CFE, mientras que el 13% (representando 43.22 ha) son destinadas a la construcción de las vialidades. Por último, el restante 11% corresponde a la superficie para la construcción de las vías de ferrocarril (aproximadamente 36.03 ha).

La decisión de dividir el desarrollo de la infraestructura portuaria para la ampliación del puerto de Manzanillo en el interior de la Laguna de Cuyutlán, se basa principalmente en las proyecciones de carga que podrían ser manejados por el sistema portuario Manzanillo–Cuyutlán, siendo Cuyutlán donde se concentraría la carga contenerizada, se ha estimado que entre la TEC I y la TEC II tendrán la capacidad suficiente para cubrir la demanda del movimiento de Contenedores hasta el 2025, por lo que el desarrollo de la segunda etapa, sería posterior a este año.

6.3.1 Primera Etapa de Desarrollo.

La primera etapa de desarrollo contempla la construcción de dos terminales especializadas en el manejo de contenedores.

a. Terminal Especializada de Contenedores No. I (TEC I)

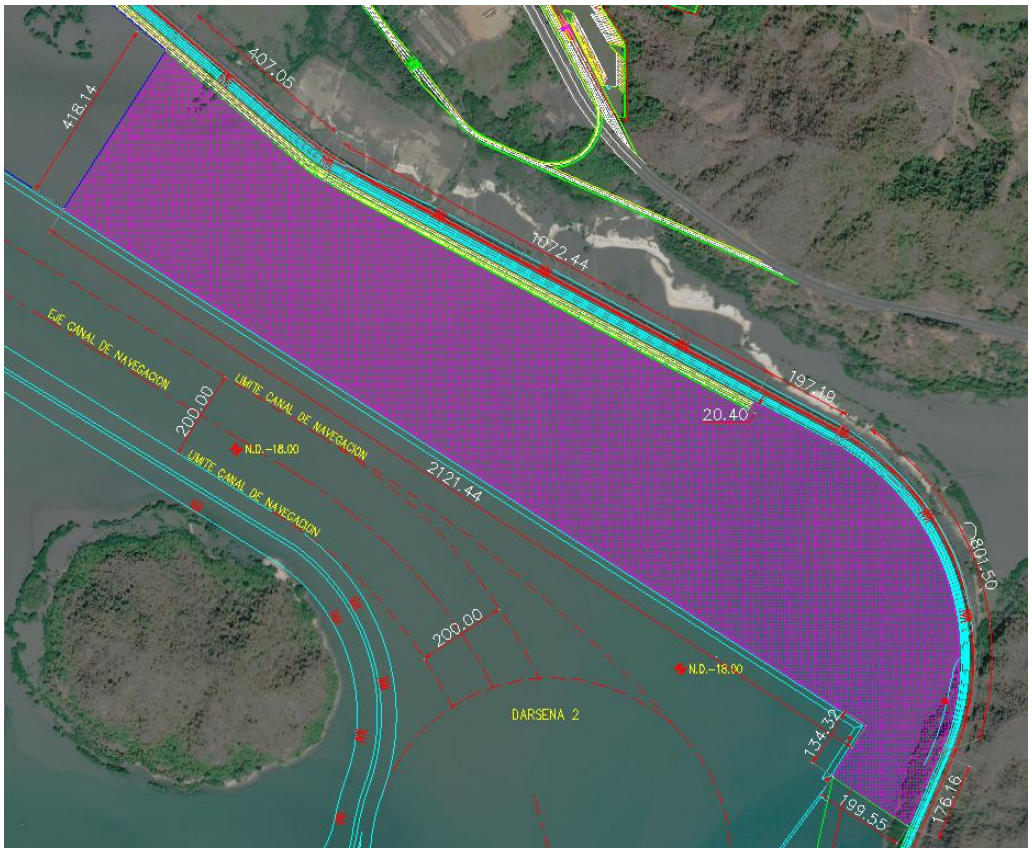
La TEC I será la primera terminal especializada en el manejo de contenedores en la ampliación del puerto en la Laguna de Cuyutlán, la cual será construida sobre terrenos ganados al cuerpo lagunar, esta se localizará contigua a la margen norte de la laguna, ver Figura 6.15.

Tendrá una superficie total de 95.00 ha, de las cuales 14.99 ha (lo que representa el 15.78% del total de la superficie) corresponden a la zona de revisión de contenedores.

La superficie de desarrollo para la infraestructura de la TEC I será de 80.01 ha, en la cual se estima una superficie de almacenamiento dinámico de contenedores de 4.24 millones de TEU’s anuales.

Tendrá un frente de atraque de 2,121.44 m, con la cual se podrá recibir hasta 3 portacontenedores tipo MGX-24 (eslora: 400 m, manga: 61 m y calado: 17.5 m) con una capacidad de 24,000 TEU’s y un portacontenedores tipo Post Panamax I (eslora: 300 m, manga: 40 m y calado: 13 m) con una capacidad de 6,000 TEU’s.

Figura 6.15 Área de Desarrollo Terminal Especializada de Contenedores No. I.



Fuente: Elaboración propia, 2026

b. Terminal Especializada de Contenedores No. II (TEC II)

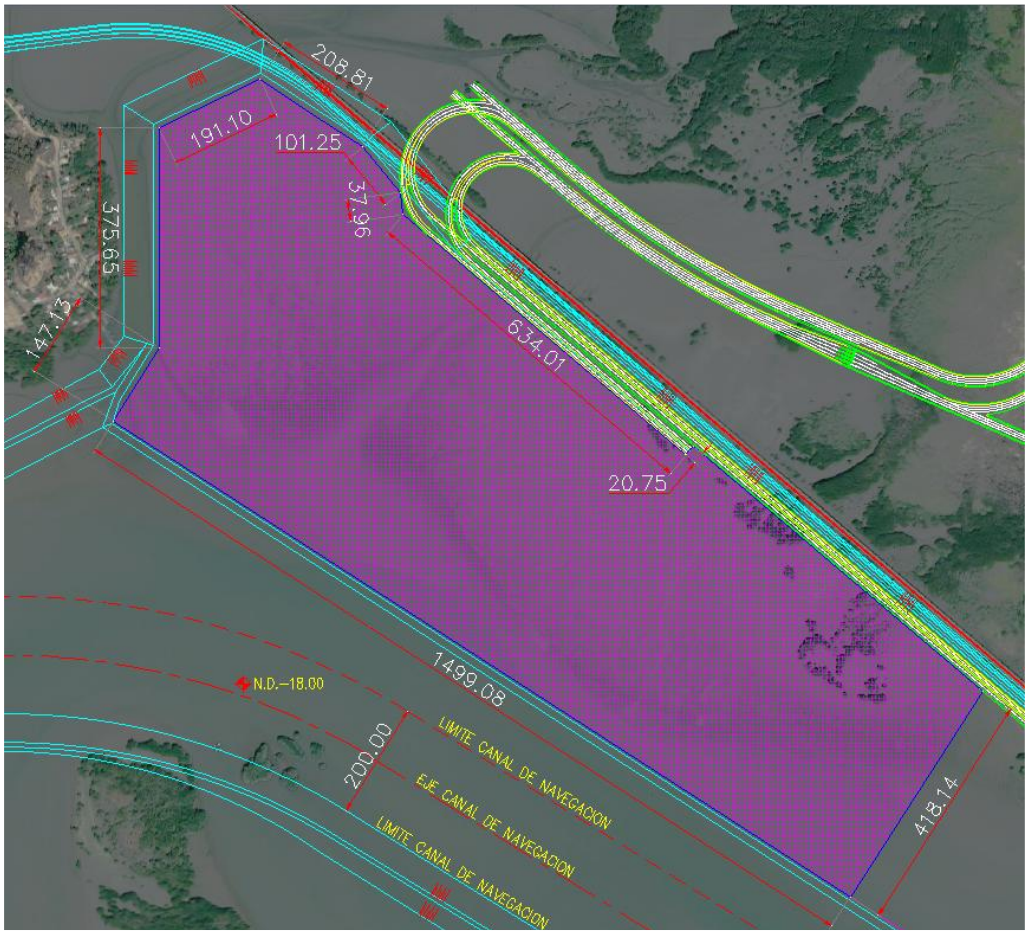
La TEC II, tendrá una superficie total de 82.15 ha, de las cuales 13.00 ha (lo que representa el 15.82% del total de la superficie) corresponden a la zona de revisión de contenedores., ver Figura 6.16.

Considerando lo anterior, la superficie de desarrollo para la infraestructura será de 69.15 ha, en la cual se estima una superficie de almacenamiento dinámico de contenedores de 3.66 millones de TEU's anuales.

Tendrá un frente de atraque de 1,499.08 m, con la cual se podrá recibir hasta 2 portacontenedores tipo MGX-24 (eslora: 400 m, manga: 61 m y calado: 17.5 m) con una capacidad de 24,000 TEU's y un portacontenedores tipo Post Panamax I (eslora: 300 m, manga: 40 m y calado: 13 m) con una capacidad de 6,000 TEU's.

La capacidad total de almacenamiento de contenedores entre las dos terminales de la primera etapa es de 7.90 millones de TEU´s, lo cual brinda una capacidad para cubrir la demanda hasta el año 2050.

Figura 6.16 Área de Desarrollo Terminal Especializada de Contenedores No. II.



Fuente: Elaboración propia, 2026

c. Vías de Comunicación.

Las dos terminales se comunicarán a tierra mediante vialidades, tanto a nivel como viaductos elevados. La superficie total de las vialidades es de 27.40 ha, por lo tanto y de acuerdo

con la tabla 6.5, implica que 7.05 ha de vialidades se localizan dentro la plataforma donde se localizan las dos terminales especializadas de contenedores.

La longitud total de las vialidades suma 15.51 km, de los cuales 7.82 km son vialidades a nivel y 7.69 km son elevados, ver Tabla 6.7.

Tabla 6.7 Longitud de Vialidades en la Primer Etapa de Desarrollo.

No. de Carriles	Vialidades			
	A Nivel	Viaducto Elevado	Total	
	(m)	(m)	(m)	(%)
4	2,172.05	407.05	2,579.10	17%
8	290.73		290.73	2%
5	1,496.11	2,595.99	4,092.10	26%
3	3,686.70	1,111.17	4,797.87	31%
2	172.16	3,572.68	3,744.84	24%
Total	**7,817.74**	**7,686.89**	**15,504.63**	**100%**

Fuente: Elaboración propia, 2026

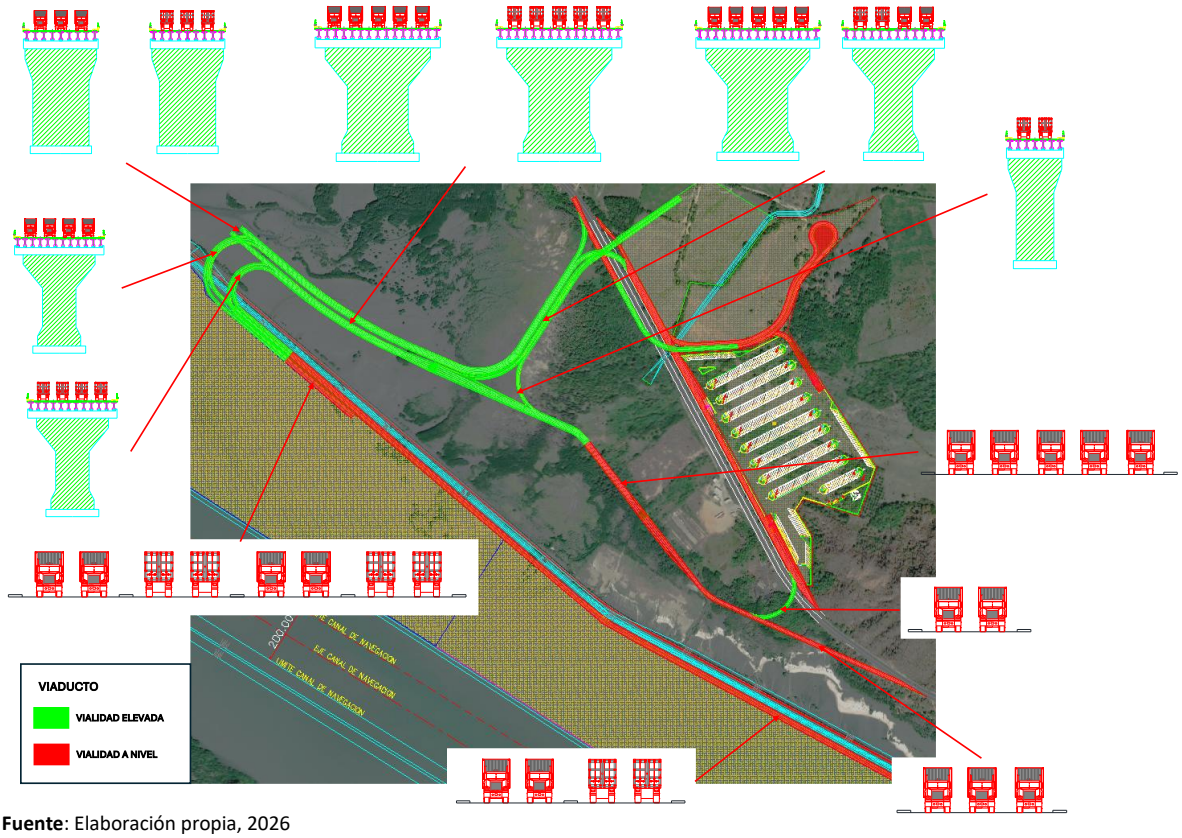
El 31% de la longitud total de las vialidades corresponde a vialidades de 3 carriles, de los 4.8 km de longitud, el 77% esta constituido por 3.70 km y el restante 23% (1.11 km) a tramos elevados. En segundo lugar, lo representa las vialidades de 5 carriles que representan el 26% (4.10 km) de la longitud total de la longitud de vialidades, de esta longitud el 63% (2.60 km) corresponde a tramos elevados y el restante 37% (1.50 km) a vialidades a nivel.

El tercer lugar lo ocupan las vialidades de dos carriles con el 24% de la longitud total, de los 3.74 km de longitud, el 95% (3.57 km) corresponde a tramos elevados y el restante 5% (0.17 km) a tramos a nivel. El tramo de 4 carriles ocupa el cuarto lugar con el 17% del total de la longitud (2.60 km), el 84% que representa 2.17 km son tramos a nivel y el restante 16% (0.41 km) a tramos elevados. El restante 2%, lo representa las vialidades de 8 carriles (0.29 km) de la longitud total, siendo el total a tramos a nivel.

d. Ferrocarril.

En el caso especial del ferrocarril, se ha planteado la necesidad de que el 70% de la carga sea movida por ferrocarril, lo anterior implica que la vía existente sea insuficiente para dicha tarea. Por tal motivo, se ha planteado la construcción de cuatro líneas adicionales a la existente, ver Figura 6.18.

Figura 6.17 Vialidades de la Primera Etapa de Desarrollo.



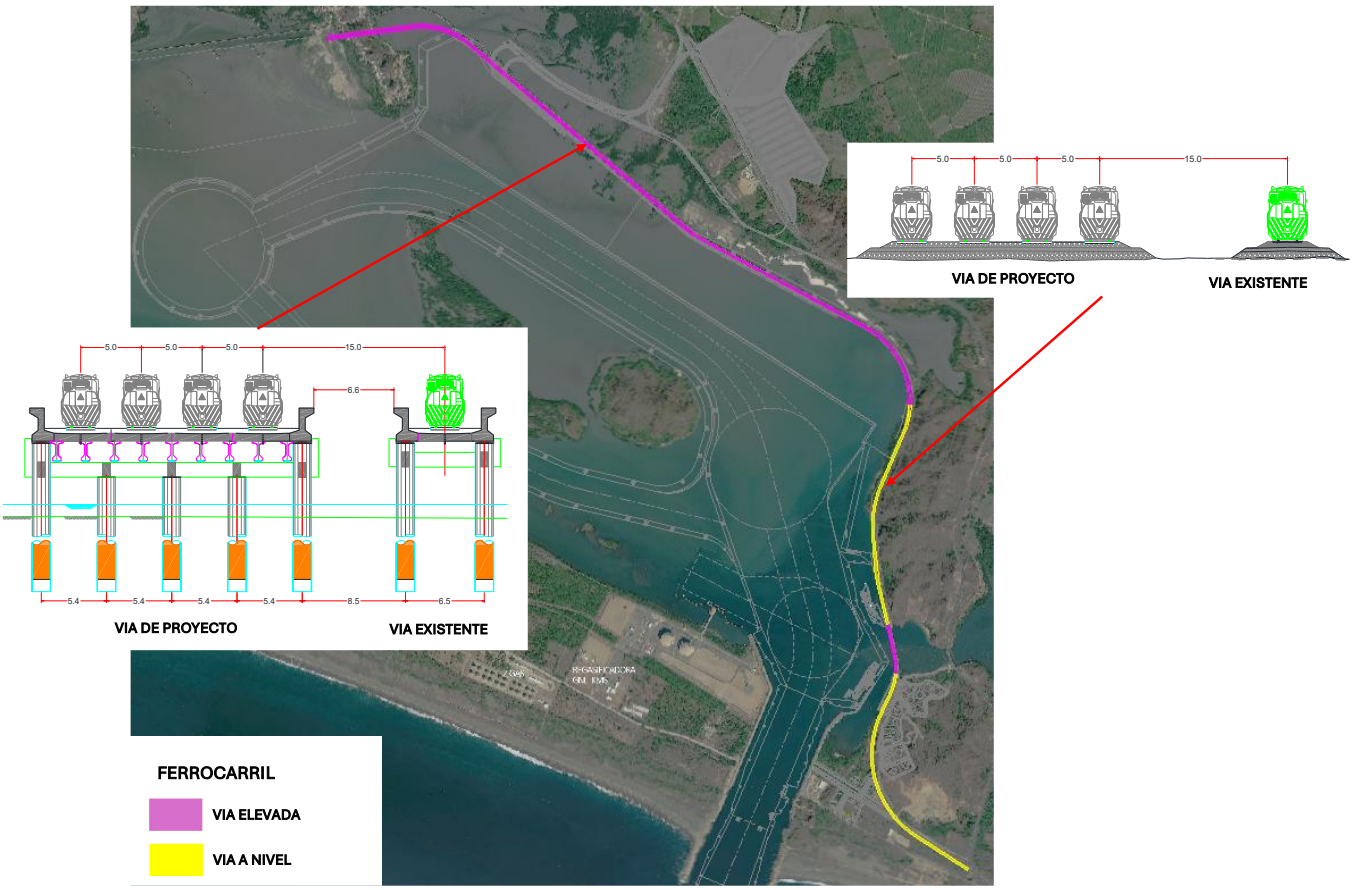
Fuente: Elaboración propia, 2026

Para la primera etapa, la línea de ferrocarril tendría una longitud de 8.28 km, de los cuales el 62% (lo que representa 5.17 km) deberán ser construidos mediante un viaducto elevado y el restante 38% (aproximadamente 3.11 km) deberán ser construido a nivel de terreno.

Por otra parte, si se considera que son cuatro líneas de ferrocarril, la longitud total de vías es de 33.11 km.

Por último, es importante comentar que el área que ocupará el desarrollo de la infraestructura ferroviaria suma en total 14.32 ha, de las cuales el 36% (5.13 ha) son tramos en superficie y el restante 64% (9.18 ha) corresponden a un viaducto elevado.

Figura 6.18 Sistema de Vías Férreas de la Primera Etapa de Desarrollo.



Fuente: Elaboración propia, 2026

e. Áreas Externas.

A parte del área destinada para el desarrollo de las dos terminales especializadas de contenedores, se han contemplado tres áreas externas, que en conjunto suman aproximadamente 51.12 ha, de las cuales el 25.97% (13.28 ha) corresponde a la superficie destina a complementar las actividades de revisión de los contenedores, el 22.68% que representa 13.13 ha corresponde a la superficie destinada a la zona administrativa y de servicios. El restante 48.35% (24.71 ha) estará destinado a un estacionamiento de tractocamiones, aproximadamente en esta superficie se tendría un mínimo de 640 cajones de estacionamiento.

Las áreas externas del desarrollo portuario estarán localizadas al norte de la Laguna de Cuyutlán contiguas a la autopista Colima–Manzanillo, en dirección hacia Manzanillo.

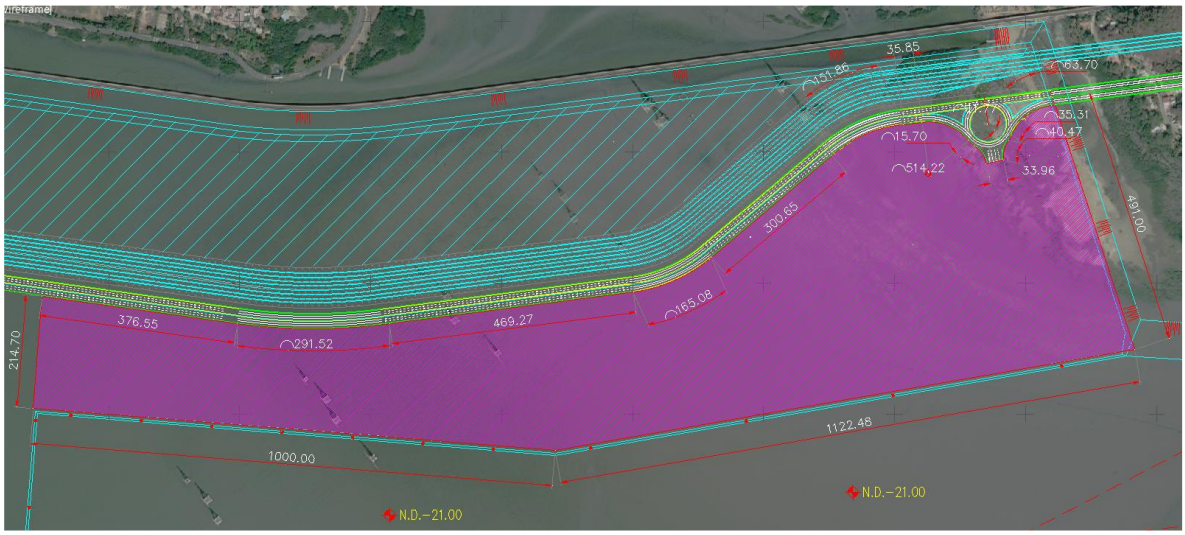
6.3.2 Segunda Etapa de Desarrollo.

La segunda etapa de desarrollo contempla la construcción de tres terminales especializadas, dos en el manejo de contenedores y una que tendrá la función de una terminal de usos múltiples o de cabotaje.

a. Terminal Especializada de Contenedores No. III (TEC III)

La TEC III será construida sobre terrenos ganados al cuerpo lagunar, esta se localizará hacia el noroeste de la laguna, ver Figura 6.19.

Figura 6.19 Área de Desarrollo Terminal Especializada de Contenedores No. III.



Fuente: Elaboración propia, 2026

Tendrá una superficie total de 63.12 ha, del total de esta superficie se destinará el 20% (12.68 ha) a la zona de revisión de contenedores. Por lo tanto, la superficie de desarrollo para la infraestructura de la TEC I será de 50.44 ha, en la cual se estima una capacidad de almacenamiento dinámico de contenedores de 2.48 millones de TEU's anuales.

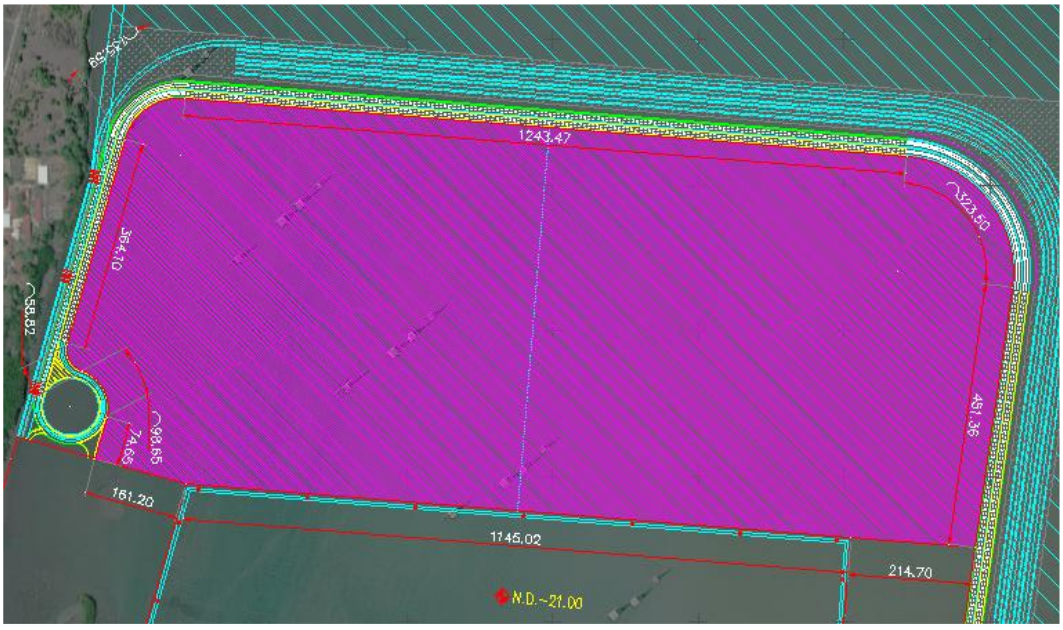
El frente de atraque estará dividido en dos muelles, debido a que la orientación del frente de atraque no es recto, el primero de ellos tendrá una longitud de 1,122.48 m y el segundo de

1,000.00 m, dando un total de 2,122.48 m, con la cual se podrá recibir hasta 4 portacontenedores tipo MGX-24 (eslora: 400 m, manga: 61 m y calado: 17.5 m) con una capacidad de 24,000 TEU's).

b. Terminal Especializada de Contenedores No. IV (TEC IV)

La TEC II, tendrá una superficie total de 82.15 ha, de las cuales 13.00 ha (lo que representa el 15.82% del total de la superficie) corresponden a la zona de revisión de contenedores., ver Figura 6.20.

Figura 6.20 Área de Desarrollo Terminal Especializada de Contenedores No. IV.



Fuente: Elaboración propia, 2026

c. Terminal de Usos Múltiples No. V (TUM V)

La ultima de las terminales estará destinada a una Terminal de Usos Múltiples (TUM) que también tendrá la función de atender el tráfico de cabotaje. Esta terminal tendrá una superficie de 15.00 ha, ver Figura 6.21.

Contará con un frente de atraque de 500 m, con lo cual, podrá recibir embarcaciones de 150,000 TPM (eslora de 294 m, manga de 45.9 y un calado de 17.5 m)

Figura 6.21 Área de Desarrollo de la Terminal de Usos Múltiples No. V.

d. Vías de Comunicación.

Las tres terminales se comunicarán a tierra mediante vialidades a nivel principalmente y un tramo elevado que se conecta a las vialidades construidas en la primera etapa. La superficie total de las vialidades es de 43.22 ha, de las cuales, 39.67 ha (92% del total) corresponden a vialidades a nivel y se localizan dentro de la plataforma y el restante 3.54 ha (8%) al tramo elevado.

Las vialidades de la segunda etapa tienen tres carriles, tanto el tramo superficial como el elevado. La longitud total de las vialidades suma 12.12 km, de los cuales 9.76 km son vialidades a nivel y 2.36 km son elevados, ver Tabla 6.8.

e. Ferrocarril.

Para la segunda etapa, la línea de ferrocarril contaría con 8 vías, las cuales tendrían una longitud de 4.12 km cada una, más un tramo de dos vías con una longitud de 0.85 km, todas construidas a nivel de terreno, ver Figura 6.23.

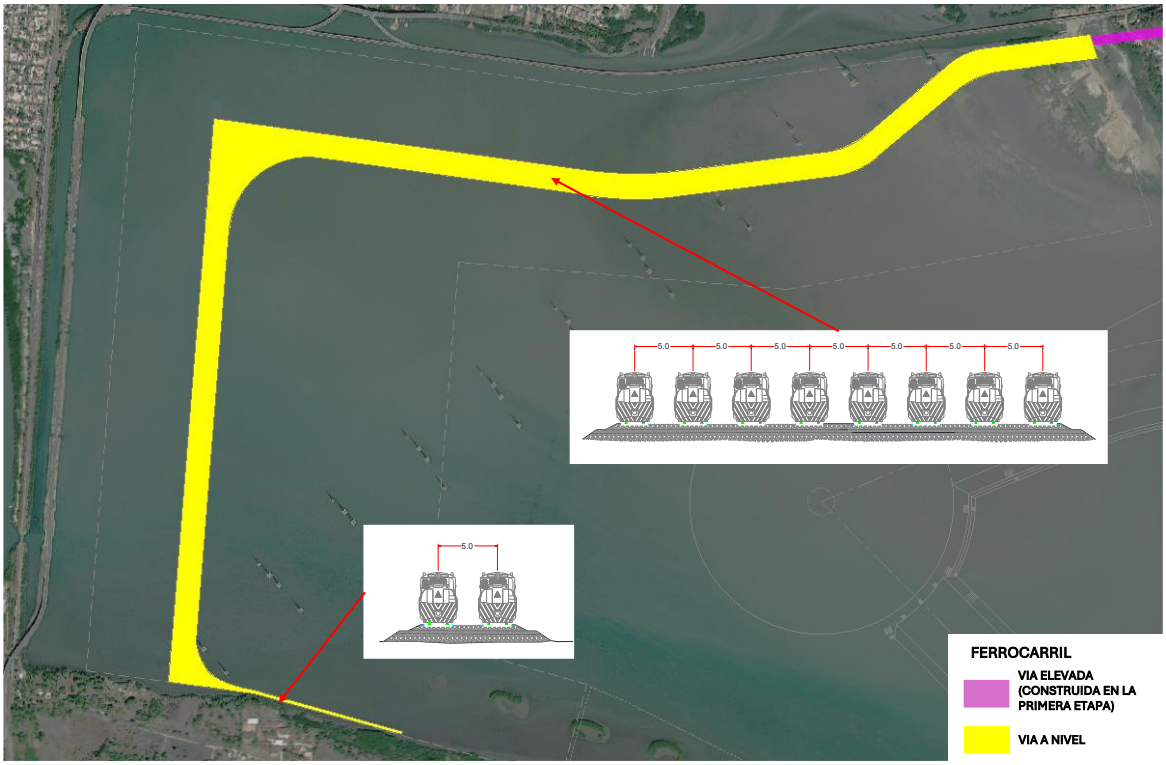
Figura 6.23 Sistema de Vías Férreas de la Segunda Etapa de Desarrollo.



Fuente: Elaboración propia, 2026

Considerando todos los tramos de vías, la longitud total de vías es de 34.63 km. Por último, es importante comentar que el área que ocupará el desarrollo de la infraestructura ferroviaria suma en total 36.03 ha.

f. Área para Reubicación de las Torres de CFE.

Para poder implementar la segunda etapa de desarrollo, es necesario reubicar las torres de alta tensión de CFE que se localizan en la zona de proyecto ver Figura 6.24, para tal caso, se ha destinado una superficie de 101.81 ha dentro de la plataforma de desarrolla de la segunda etapa, lo que representa el 30% de la superficie total.

7.0 CONCLUSIONES Y RECOMENDACIONES.

7.1 Conclusiones.

1. El análisis integral del Puerto de Manzanillo y su proyección hacia el año 2050 confirma que el sistema portuario se encuentra en una etapa de transición estructural. La evolución histórica del tráfico contenerizado, que ha llevado al puerto a niveles cercanos a los cuatro millones de TEU's anuales y más de treinta millones de toneladas totales, ha generado un entorno operativo caracterizado por alta intensidad de uso, reducción progresiva de holguras y creciente sensibilidad a la variabilidad logística. Esta condición no representa una crisis inmediata, pero sí evidencia que el recinto histórico ha alcanzado un nivel de madurez avanzada donde el crecimiento adicional requiere una redefinición estratégica.

2. Las trayectorias proyectadas hacia 2050 —con rangos que oscilan entre aproximadamente cinco y más de los diez millones de TEU's— no dependen exclusivamente de la demanda internacional o del crecimiento económico nacional. Dependen, sobre todo, del régimen operativo que se adopte.

3. Si la ampliación hacia Cuyutlán se limita a incrementar capacidad física sin modificar la arquitectura logística, el sistema podrá sostener crecimiento en el corto y mediano plazo, pero tenderá a converger nuevamente hacia límites estructurales de capacidad efectiva. En este escenario incremental, el puerto ampliado seguiría operando bajo una lógica de recinto concentrado, con patios como reguladores forzados y accesos terrestres como factor determinante del techo operativo. El crecimiento sería real, pero con rendimientos decrecientes y mayor exposición a variabilidad.

   En contraste, si la expansión se concibe bajo un modelo port-led maduro, la transformación no será únicamente espacial sino funcional. El desacople entre muelle, patio y el hinterland permitiría elevar la capacidad máxima efectiva sin depender exclusivamente del aumento de superficie interna. La integración de plataformas externas, la consolidación de la intermodalidad ferroviaria y la coordinación institucional sistémica reducirían la variabilidad operativa y mejorarían la resiliencia del sistema. En este contexto, el puerto ampliado no solo crecería en volumen, sino en estabilidad y confiabilidad logística.

4. El escenario de mayor ambición, en el cual Cuyutlán se convierte en el nuevo polo dominante, implica una reconfiguración geográfica del sistema portuario. Esta opción permitiría posicionar al sistema Manzanillo–Cuyutlán como un nodo logístico de referencia en el Pacífico ampliado, con capacidad para absorber volúmenes superiores a los diez millones de TEU´s hacia 2050. No obstante, este escenario exige condiciones técnicas y de gobernanza más complejas, así como inversiones significativas y una gestión ambiental rigurosa, particularmente en un entorno lagunar sensible.

5. El análisis comparativo demuestra que la diferencia entre escenarios no es meramente cuantitativa. Se trata de elegir entre un crecimiento que amplía infraestructura y uno que transforma arquitectura. La capacidad nominal puede incrementarse mediante obra física, pero la capacidad efectiva solo se eleva de manera sostenida cuando el sistema reduce su variabilidad, mejora su integración territorial y fortalece su gobernanza.

6. En términos estratégicos, el escenario central emerge como la trayectoria óptima de planeación. Este escenario equilibra ambición y factibilidad, eleva la capacidad efectiva, reduce el riesgo de saturación estructural y preserva la posibilidad de evolucionar hacia un modelo dominante si las condiciones económicas y comerciales lo justifican. Representa una transformación gradual pero profunda, en la que la expansión hacia Cuyutlán no se limita a agregar muelles, sino que articula un sistema logístico ampliado.

7. La decisión estratégica para el sistema Manzanillo–Cuyutlán no debe centrarse exclusivamente en cuánto construir, sino en cómo operar. La infraestructura es condición necesaria, pero no suficiente. La sostenibilidad al 2050 dependerá de la capacidad del sistema para funcionar como red integrada, reducir la dependencia de nodos individuales, desacoplar funciones críticas y gestionar de manera coordinada la interacción entre mar y territorio.

8. En definitiva, el futuro del Puerto de Manzanillo no está determinado únicamente por el comercio global, sino por la arquitectura operativa que se decida implementar. La ampliación hacia Cuyutlán representa una oportunidad histórica para transitar de un modelo de crecimiento incremental a un modelo de desarrollo sistémico. La magnitud del impacto regional y nacional dependerá de la profundidad con la que se asuma esta transformación.

9. La decisión estratégica no es solo construir más puerto, sino construir un sistema.

10. El límite de 24,000 TEU’s en la capacidad de los buques portacontenedores que vemos hoy a nivel mundial es, más o menos, un reflejo de los límites económicos tanto como los de la infraestructura portuaria, la forma de las vías fluviales más transitadas del mundo y la ingeniería. La ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán debe contemplar una flota de diseño que cubra los intereses comerciales del puerto a medio y largo plazo. Si bien parece claro que los buques SMX y VLCC están claramente definidos, se recomienda que, de cara a la terminal de contenedores, se tengan en cuenta las tendencias actuales en la flota.

    Principalmente porque en la mayoría de los puertos, para que estos puedan recibir las embarcaciones más grandes que existen hoy, se requeriría de una gran revisión de la infraestructura portuaria, lo que sería increíblemente costoso. Los buques más grandes también están restringidos en cuanto a las rutas por las que navegan porque son muy vulnerables a las inclemencias del tiempo.

11. El buque de diseño queda definido por la siguiente flota de buques portacontenedores:

    - Maxi Neo-Panamax [369 x 51.2 x 15], buque de mayores dimensiones que ha pasado por las nuevas esclusas de Panamá, cargando hasta 14.500 TEU's.

    - Nuevos Clase E [E = 398 m, Manga = 56 m y Calado = 15.5 m], buques con hasta 21.000 TEU's de capacidad.

    - Megamax 24 (MGX24), [E = 400 m, Manga = 61.5 y Calado = 16.5 m (max = 17.7 m)], buques con hasta 24.000 TEU's de capacidad.

12. En las obras de dragado, el condicionante más decisivo es el tipo de barco que utilizará las instalaciones portuarias de la ampliación en la Laguna de Cuyutlán y las características de estas dimensiones (eslora, manga y calado), condiciones de maniobrabilidad y necesidades de superficie de fondeo.

    En la planificación de la ampliación se deberá tener en cuenta, como base de los cálculos, el barco máximo que deba entrar a puerto junto con las características que se fijen para la navegación. Asimismo, la profundidad a que debe dragarse las áreas de navegación se estimará teniendo en cuenta que se deberá disponer en todo momento y circunstancia la profundidad para que la navegación del buque en la zona portuaria sea segura siempre deberá existir una profundidad de agua adecuada por debajo del buque denominada zona de resguardo.

13. El Vaso II de la Laguna de Cuyutlán constituye un ecosistema lagunar somero con alto valor ecológico y elevada sensibilidad ambiental. Su estabilidad depende de procesos hidrológicos delicados y del equilibrio entre productividad y reciclaje de nutrientes.

    Con base en condiciones hidrológicas, estructura vegetal y presiones identificadas, el manglar del Vaso II puede considerarse funcional pero vulnerable. Su persistencia depende del mantenimiento de conectividad hídrica adecuada, control de aportes contaminantes y prevención de nuevas fragmentaciones.

    Las presiones actuales incrementan la probabilidad de simplificación biológica y pérdida de funcionalidad si no se implementan medidas de manejo integradas basadas en monitoreo continuo, restauración de hábitats y regulación de actividades que alteren su dinámica hidrológica.

    El estado puede clasificarse como intermedio, con tendencia a deterioro en ausencia de manejo específico orientado a restauración hidrológica y conservación de bordes vegetados.

14. El Vaso II de la Laguna de Cuyutlán constituye un subsistema ambientalmente sensible cuyo funcionamiento depende de la interacción equilibrada entre componentes abióticos y bióticos. La capacidad de carga del sistema está estrechamente vinculada a su morfología somera, su régimen hidrodinámico natural y la presencia de manglar e islotes que actúan como reguladores físicos.

    Cualquier ampliación portuaria deberá dimensionarse dentro de estos límites físicos y ecológicos, incorporando criterios de diseño adaptativo y monitoreo permanente que permitan mantener la integridad funcional del sistema lagunar.

15. Dentro de esta dimensión se evaluaron cuatro subcriterios. El primero corresponde a la eficiencia náutica, que analiza la calidad geométrica del canal de acceso, la suficiencia del círculo de maniobra, la disposición de frentes de atraque y la seguridad en operaciones simultáneas. Este subcriterio incide directamente en la productividad portuaria y en la reducción de riesgos marítimos.

    El segundo subcriterio es la eficiencia logística interna, que valora la organización espacial de patios, conectividad terrestre, distancias operativas y potencial de automatización. Una configuración compacta y jerarquizada favorece menores tiempos de ciclo y mayor rendimiento por hectárea.

    El tercer subcriterio corresponde a la capacidad de crecimiento modular, entendida como la posibilidad de ampliar el desarrollo por etapas sin afectar operaciones en curso. Este aspecto es fundamental para reducir riesgos financieros y permitir adaptación progresiva a la demanda.

    El cuarto subcriterio es la flexibilidad de tipos de carga, que mide la capacidad de la alternativa para atender distintos segmentos del mercado marítimo, incluyendo contenedores de ultra gran tamaño, graneles y energéticos, así como su adaptabilidad a cambios futuros en patrones de comercio.

    La aplicación del modelo de ponderación arrojó los siguientes resultados globales:

    - Alternativa 1: 8.59
    - Alternativa 2: 9.46
    - Alternativa 3: 9.71

    La Alternativa 3 obtuvo la calificación más alta, derivado de su configuración, destacó por su alto potencial estratégico, adecuada organización náutica y menor nivel de alteración estructural del sistema lagunar en comparación con la alternativa que contempla una nueva bocana oceánica.

16. En atención a los criterios emitidos por la autoridad ambiental, se reconoce que la viabilidad del proyecto está condicionada a la demostración técnica de la compatibilidad del diseño propuesto con el sistema lagunar.

    En este sentido, la selección de la Alternativa 3 no constituye una validación automática de su viabilidad ambiental, sino una **base técnica para el desarrollo de un proyecto definitivo**, el cual deberá ser sometido a evaluación mediante una Manifestación de Impacto Ambiental en su modalidad regional (MIA-R), incorporando:

    - Modelación hidrodinámica tridimensional calibrada
    - Análisis de transporte de sedimentos y colmatación
    - Evaluación de cambios en salinidad, tiempos de residencia y calidad del agua
    - Análisis de afectación a manglar y hábitats asociados
    - Evaluación de impactos acumulativos y sinérgicos

    La viabilidad final del proyecto dependerá del cumplimiento de estos elementos y de la capacidad del diseño para demostrar que los impactos pueden ser evitados, mitigados o compensados de manera verificable.

17. El dimensionamiento del proyecto no se define exclusivamente por criterios de capacidad portuaria, sino por la capacidad ambiental del sistema receptor, la cual actúa como condicionante del diseño

ANEXO A

El "cuello de botella" ambiental-institucional se puede describir con bastante precisión porque, según reportes de prensa basados en el resolutivo de la DGIRA (SEMARNAT), la autoridad no solo "pidió aclaraciones": determinó que el trámite no podía continuar en la forma en que se presentó, porque las modificaciones y reconfiguraciones planteadas para el "Desarrollo del Puerto Nuevo Manzanillo en el Vaso II" rebasaban el alcance de la evaluación original y, por tanto, podían implicar impactos no evaluados y riesgos potencialmente irreversibles para el sistema lagunar.

A.1 Qué significa, en términos técnicos y administrativos, el "no autorizó" de SEMARNAT.

Lo que se reporta es que la Dirección General de Impacto y Riesgo Ambiental (DGIRA) revisó la MIA-R (y/o su modificación) y concluyó que los ajustes propuestos por la promovente para "reducir afectación al manglar" y disminuir impactos directos sobre islotes (mencionados públicamente como "Islas Cocodrilo I y II") no eran ajustes menores, sino una redistribución integral del puerto. Esa redistribución, a su vez, implicaría nuevas obras, nuevos dragados y uso de superficies no contempladas originalmente, con consecuencias sobre la hidrodinámica del vaso y el trasvase/redistribución de sedimentos dentro del sistema lagunar.

En términos prácticos, esto coloca el problema en un punto muy específico: la autoridad considera que el "proyecto real" (tal como terminaría construido) ya no coincide con el "proyecto evaluado". Cuando ocurre esa divergencia, SEMARNAT/DGIRA suele exigir que el promovente reingrese con una evaluación que corresponda a la configuración que realmente pretende ejecutar, en vez de "parchar" la evaluación con modificaciones que cambian sustancialmente la huella, el diseño y los procesos físicos (dragado, rellenos, circulación) que determinan el impacto. De hecho, en notas que citan el resolutivo se señala que, para replantear o modificar el proyecto, la promovente tendría que presentar una nueva MIA en modalidad regional, conforme al marco aplicable.

Esa decisión convierte la "compatibilidad ambiental" en el problema inmediato porque, mientras el proyecto no tenga una autorización vigente y consistente con el diseño final, no existe una base legal-técnica para ejecutar obras, y además persiste el riesgo de que cualquier avance físico incremente el conflicto y agrave el criterio precautorio, como también se ha discutido públicamente.

A.2 Qué pide "en el fondo" SEMARNAT, aunque no lo exprese como lista de requisitos

Lo que la DGIRA está poniendo sobre la mesa es una exigencia de coherencia técnica y cierre de incertidumbre sobre procesos clave del Vaso II: si la reconfiguración introduce nuevos dragados, nuevas superficies y trayectorias hidráulicas, entonces deben evaluarse formalmente los

efectos sobre circulación, tiempos de residencia, salinidad, transporte de sedimentos, colmatación y erosión, y los impactos derivados sobre manglar, planicies someras e islotes.

En una laguna somera, esos procesos no son “detalles”: son los mecanismos que definen si el sistema cambia de régimen, y por eso la autoridad habla de riesgos potencialmente irreversibles.

A.3 Soluciones para dar cumplimiento a lo indicado por SEMARNAT y destrabar el cuello de botella.

La solución no es “defender el documento”, sino rearmar el caso técnico para que el proyecto evaluado sea el proyecto ejecutable, y para que los impactos identificados (incluidos los de mayor magnitud) tengan una ruta verificable de evitación, minimización y manejo. En términos concretos, las soluciones se agrupan en cinco frentes que se refuerzan entre sí.

1. Reingresar la evaluación con un proyecto definitivo y trazable

La primera medida es asumir la implicación del resolutivo: si la DGIRA concluye que la modificación “rebasa el alcance”, lo procedente es presentar una nueva MIA-R que describa la configuración final (geometría de canal y dársenas, polígonos de relleno, huella de terminales, fases) y que documente alternativas reales (incluida alternativa de localización, alternativa de menor huella, alternativa por fases). Esto está alineado con lo que se reporta que SEMARNAT señaló: para cualquier replanteamiento, debe ingresarse una nueva MIA-R conforme a LGEEPA y reglamentación.

Aquí la clave es evitar una nueva “brecha” entre lo evaluado y lo ejecutado. El expediente debe incluir control de cambios de ingeniería, planos y memorias consistentes, y un modelo de fases que impida que la obra “se reconfigure” durante construcción sin volver a evaluar.

2. Cerrar la incertidumbre hidrodinámica y sedimentaria con modelación calibrada

Dado que DGIRA menciona explícitamente alteraciones hidrodinámicas y trasvase de sedimentos como preocupación técnica, el corazón de la solución es desarrollar y anexar un paquete robusto de modelación, no solo descriptivo.

Eso implica, como mínimo, un modelo hidrodinámico 2D/3D calibrado con campañas estacionales en el Vaso II (marea, viento, salinidad, temperatura, OD, velocidades) y un modelo de transporte de sedimentos (finos cohesivos) que permita comparar “sin proyecto” vs “con proyecto” y, crucialmente, “con proyecto por fases”. El objetivo es demostrar, con métricas, que el diseño no dispara tiempos de residencia, no crea zonas muertas persistentes, no incrementa hipersalinidad/estratificación y no genera un patrón de erosión/colmatación que haga inviable el

mantenimiento. Esta evidencia es la que responde directamente al núcleo del resolutivo reportado.

3. Rediseño geométrico condicionado por capacidad de carga del Vaso II

La tercera solución es de ingeniería: si el resolutivo advierte que la reconfiguración implica nuevas obras y dragados con efectos sistémicos, entonces el diseño debe redimensionarse para que el Vaso II no se convierta en un sistema dependiente de dragado crónico y defensas permanentes.

Eso típicamente requiere reducir huella de rellenos, optimizar secciones del canal (ancho y taludes al mínimo de seguridad), limitar áreas profundas, conservar o recrear estructuras morfodinámicas (por ejemplo, mantener islotes donde sea compatible o generar "islotes funcionales" de baja elevación para disipación/depósito), y definir velocidades máximas de navegación internas para reducir socavación en márgenes y estrés sobre manglar. La compatibilidad con manglar e islotes deja de ser un "programa de reforestación" y se vuelve un "diseño por restricción física".

4. Mitigación basada en desempeño y verificación, no solo en compromisos

Para que SEMARNAT considere que el riesgo de irreversibilidad está atendido, no basta prometer medidas; hay que proponer un sistema de gestión adaptativa con umbrales y consecuencias. Esto se traduce en un programa de monitoreo ambiental con indicadores operativos (turbidez, OD, salinidad, nutrientes, tasas de colmatación, estabilidad de márgenes, condición del manglar) y reglas tipo "si ocurre X, se detiene/ajusta Y". Es decir, pasar de mitigación "de papel" a mitigación "por desempeño", con capacidad real de corregir.

5. Fortalecimiento del componente social y de transparencia del proceso

Aunque el resolutivo que citas es ambiental-técnico, el contexto público muestra que el proyecto está rodeado de controversia y de demanda de información y consulta efectiva.

Una ruta de cumplimiento y viabilidad suele requerir, además de la nueva MIA-R robusta, un paquete de comunicación técnica pública, mesas de trabajo y acuerdos verificables con sectores dependientes de la laguna (pesca, salinas), y trazabilidad de cómo se incorporan sus preocupaciones en el diseño (por ejemplo, preservación de accesos, zonas de resguardo, programas de compensación y reconversión cuando aplique). Esto reduce el riesgo de que el proyecto vuelva a trabarse por conflictividad y por cuestionamientos al proceso.

1.0 INTRODUCCIÓN

Con base en las propuestas correspondientes a la primera y segunda etapa de desarrollo, se advierte que el proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán presenta una estructura territorial y funcional claramente definida a nivel de implantación general. Se reconoce una organización lineal del desarrollo portuario sobre el borde norte de la laguna, con una secuencia de terminales, frentes de atraque, patios de respaldo, corredor vial principal, infraestructura ferroviaria, áreas de apoyo logístico y zonas administrativas y de servicios.

Asimismo, en el presente documento se formula exclusivamente para establecer el planteamiento conceptual de las redes principales, es decir, de la infraestructura troncal, común o estructurante que deberá ser prevista, desarrollada y coordinada por el plan maestro para hacer posible la operación integral del puerto ampliado y su crecimiento por etapas. Por tal motivo, no comprende el desarrollo detallado de los proyectos internos de cada terminal, en tanto que estos serán responsabilidad de los respectivos cesionarios.

Este documento parte de la premisa de que el desarrollo portuario no puede entenderse únicamente como una suma de terminales yuxtapuestas, sino como un sistema integrado que requiere una base común de servicios, accesos, seguridad, energía, agua, drenaje, telecomunicaciones y control. Bajo esa lógica, el planteamiento de redes constituye una fase indispensable para pasar del esquema de implantación territorial a la definición de la infraestructura habilitadora del conjunto.

2.0 OBJETIVOS.

2.1 Objetivo Principal.

El objetivo principal de los servicios descritos en el presente documento es:

- El objeto del presente documento es establecer el planteamiento conceptual de las redes principales del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán, definiendo para cada sistema su función dentro del plan maestro, su criterio general de implantación, su lógica de crecimiento por etapas y su relación con las terminales concesionadas.

  No se pretende desarrollar en esta fase la ingeniería de detalle de cada red, ni determinar de manera definitiva capacidades, diámetros, calibres, cotas, equipos o especificaciones finales. El propósito consiste en formular una base técnica ordenada y coherente que sirva posteriormente para la elaboración de la ingeniería básica, la delimitación de responsabilidades, la identificación de nodos estratégicos, el establecimiento de corredores de utilidades y la definición de interfases con los cesionarios.

2.2 Objetivos Particulares.

Los objetivos particulares de los servicios descritos en el presente documento son:

- El presente planteamiento conceptual comprende la red eléctrica principal, el alumbrado exterior común, la red de agua potable y agua de servicios, la red contra incendio maestra, el drenaje pluvial maestro, el drenaje sanitario troncal, la red de telecomunicaciones y fibra óptica, el centro de control y monitoreo, el sistema general de accesos y seguridad perimetral, los corredores de utilidades asociados a vialidades, la coordinación de cruces con infraestructura ferroviaria, la atención de la zona administrativa y de servicios comunes, el abastecimiento de las áreas de apoyo logístico y estacionamiento de tractocamiones, así como la definición conceptual de las interfases entre la infraestructura del plan maestro y las futuras terminales concesionadas.

  Quedan fuera del alcance del presente documento las redes internas de distribución eléctrica, hidráulica, sanitaria, pluvial, contra incendio y de telecomunicaciones de cada terminal, así como sus edificaciones, equipos, patios y sistemas particulares de operación. No obstante, sí se establece la base conceptual para la conexión de dichas instalaciones a la infraestructura general del puerto.

3.0 MATRIZ BASE PARA EL PLANTEAMIENTO DE REDES PRINCIPALES.

El proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán contempla el desarrollo progresivo de nuevas superficies portuarias, terminales especializadas, infraestructura ferroviaria, vialidades, áreas logísticas y zonas de apoyo administrativo. La configuración territorial del proyecto, presenta una organización predominantemente longitudinal sobre el borde norte de la laguna, en la que las terminales y áreas operativas se distribuyen en secuencia a lo largo de un eje común de acceso, circulación y servicios.

En este tipo de desarrollos portuarios, la implantación de terminales no puede entenderse como un conjunto de proyectos independientes, sino como un sistema integrado que requiere una base común de infraestructura que permita su operación coordinada. Dentro de esa base común se encuentran las redes principales de servicios, las cuales constituyen la infraestructura troncal del recinto portuario.

El plan maestro tiene la responsabilidad de definir dicha infraestructura troncal, mientras que el diseño interno de cada terminal será desarrollado posteriormente por los respectivos cesionarios. En consecuencia, resulta necesario establecer desde la etapa de planeación un marco técnico que permita identificar los sistemas que deben formar parte de la infraestructura común, así como su relación con las terminales concesionadas y su crecimiento por etapas.

Para atender esta necesidad se formuló una matriz base para el planteamiento de redes principales, la cual constituye una herramienta de análisis y organización técnica del proyecto.

3.1 Matriz Base para el Planteamiento de Redes Principales.

La matriz base tiene como objetivo estructurar de manera sistemática la planificación de la infraestructura troncal del plan maestro, permitiendo identificar de forma clara los sistemas de servicios que deben ser previstos desde la planeación general del puerto, así como su alcance, su relación con las terminales concesionadas y su implementación a lo largo de las distintas etapas de desarrollo.

En proyectos portuarios de gran escala, la infraestructura de servicios no puede desarrollarse de manera aislada o en función exclusiva de las necesidades inmediatas de cada terminal. Si ello ocurriera, se producirían redes fragmentadas, interferencias entre instalaciones, falta de capacidad para el crecimiento futuro y conflictos en la delimitación de responsabilidades entre el plan maestro y los cesionarios.

La matriz permite evitar estos problemas al establecer, desde la fase conceptual, una estructura ordenada para el desarrollo de las redes principales. A través de ella se identifican los sistemas que deben considerarse infraestructura común del recinto portuario, se define el alcance

que corresponde al plan maestro y se delimita el ámbito que será responsabilidad de los cesionarios dentro de sus respectivas terminales.

Asimismo, la matriz permite analizar cada sistema en función de su papel dentro del desarrollo general del puerto, determinando qué elementos deben construirse desde la primera etapa y cuáles pueden ampliarse o consolidarse en etapas posteriores. Este enfoque es particularmente relevante en el caso del proyecto de ampliación del Puerto de Manzanillo, donde el desarrollo se llevará a cabo de forma progresiva y donde la infraestructura inicial debe diseñarse de manera que permita el crecimiento ordenado del sistema completo.

Desde el punto de vista técnico, la matriz cumple también la función de identificar los nodos principales de infraestructura, los corredores de utilidades, los puntos de interconexión con terminales y los elementos estructurales de cada red, lo cual facilita posteriormente la elaboración de la ingeniería básica y el planteamiento conceptual de las redes.

En síntesis, la matriz constituye una herramienta de planeación que permite asegurar que el desarrollo portuario se apoye en una infraestructura de servicios coherente, escalable y técnicamente integrada.

3.1.1 Estructura general de la matriz

La matriz base organiza el análisis de cada sistema de servicios considerando cinco aspectos fundamentales: el sistema o infraestructura a analizar, el alcance del plan maestro, el alcance que corresponde al cesionario, la forma en que el sistema se implementa en la primera etapa y en la segunda etapa del desarrollo, y finalmente los nodos o elementos principales que deben ser considerados dentro de la red.

Este enfoque permite visualizar cada sistema no solo como una instalación aislada, sino como parte de una estructura integrada que debe responder a las necesidades del conjunto del puerto.

3.1.2 Explicación técnica de los sistemas considerados en la matriz

3.1.2.1 Red eléctrica principal.

La red eléctrica principal constituye uno de los sistemas estructurales más importantes dentro de la infraestructura portuaria, ya que de ella depende el suministro de energía para la operación de las terminales, las áreas comunes del recinto, la iluminación exterior, los sistemas de seguridad y las instalaciones administrativas.

Desde el punto de vista del plan maestro, la red eléctrica debe concebirse como un sistema troncal que permita distribuir la energía de forma ordenada a lo largo del desarrollo

portuario. Esto implica definir el punto de interconexión con la red regional de suministro eléctrico, establecer la ubicación de una subestación principal o nodo de transformación, prever los corredores de media tensión que recorrerán el recinto y definir los puntos de entrega hacia las terminales.

La responsabilidad del plan maestro consiste en garantizar que exista una infraestructura eléctrica capaz de abastecer tanto las áreas comunes como las futuras terminales. Por su parte, los cesionarios serán responsables de desarrollar las redes de distribución interna dentro de sus predios, incluyendo la transformación a baja tensión, los centros de carga, la iluminación de patios y las instalaciones eléctricas de equipos.

La planificación de esta red debe considerar desde la primera etapa la capacidad necesaria para el crecimiento del puerto, de manera que la ampliación en etapas posteriores pueda realizarse sin necesidad de modificar la infraestructura principal.

3.1.2.2 Alumbrado exterior común.

El sistema de alumbrado exterior común forma parte de la infraestructura de seguridad y operación del recinto portuario. Su función es proporcionar condiciones adecuadas de visibilidad en accesos, vialidades, áreas administrativas, estacionamientos y espacios de circulación que forman parte de la infraestructura compartida del puerto.

El plan maestro debe definir la red de alumbrado que cubra estas áreas comunes, incluyendo postes, canalizaciones eléctricas, centros de control y criterios de iluminación. La continuidad del alumbrado a lo largo del corredor vial principal es particularmente importante para garantizar la seguridad operativa durante las horas nocturnas.

Las terminales concesionadas serán responsables del alumbrado interno de sus patios, muelles y edificios, pero la iluminación de las áreas comunes del recinto debe mantenerse bajo la responsabilidad del plan maestro para asegurar uniformidad en los niveles de iluminación y en los criterios de seguridad.

3.1.2.3 Red de agua potable y agua de servicios.

La red de agua potable y agua de servicios constituye el sistema encargado de abastecer las necesidades hidráulicas del recinto portuario. Este sistema no se limita al suministro para consumo humano, sino que también incluye el abastecimiento de agua para limpieza, servicios sanitarios, instalaciones administrativas y otras funciones operativas del puerto.

Desde el punto de vista técnico, el plan maestro debe definir el punto de abastecimiento, la infraestructura de almacenamiento y regulación, las líneas principales de conducción y los puntos de entrega hacia las terminales. La red debe diseñarse de manera que permita mantener

presiones adecuadas a lo largo de todo el desarrollo y que pueda ampliarse conforme el puerto crezca.

Los cesionarios desarrollarán sus redes internas de distribución dentro de cada terminal, pero deberán conectarse a la red principal del plan maestro en los puntos establecidos para tal efecto.

3.1.2.4 Red contra incendio maestra.

La red contra incendio constituye un sistema fundamental para la seguridad del recinto portuario. Debido a la naturaleza de las operaciones portuarias y a la presencia potencial de cargas peligrosas o inflamables, es indispensable contar con una infraestructura de protección que cubra las áreas comunes del puerto.

El plan maestro debe prever una red troncal contra incendio que incluya un sistema de almacenamiento de agua, equipos de bombeo, tuberías principales y puntos de hidrantes en áreas estratégicas del recinto. Esta red debe ser capaz de proporcionar cobertura a las áreas comunes y servir como respaldo para los sistemas internos de las terminales.

Cada cesionario será responsable de instalar sus propios sistemas de protección contra incendio dentro de su terminal, pero dichos sistemas deberán coordinarse con la red maestra del puerto.

3.1.2.5 Drenaje pluvial maestro.

El drenaje pluvial maestro es el sistema encargado de captar, conducir y disponer adecuadamente las aguas de lluvia que se generan en las superficies impermeables del puerto, tales como patios, vialidades y plataformas operativas.

En el caso del proyecto de ampliación del Puerto de Manzanillo, este sistema reviste especial importancia debido a la localización del desarrollo en una zona lagunar con niveles topográficos bajos. La planificación del drenaje pluvial debe considerar la topografía general del sitio, las pendientes de las plataformas, la ubicación de colectores principales y las estructuras de descarga o regulación.

El plan maestro debe definir el sistema general de colectores pluviales que reciba las aportaciones de las áreas comunes y de las terminales. Por su parte, cada cesionario será responsable de diseñar el drenaje pluvial interno de su terminal y de conectarlo al sistema maestro en los puntos previamente definidos.

3.1.2.6 Drenaje sanitario troncal.

El drenaje sanitario troncal es el sistema encargado de conducir las aguas residuales generadas en las áreas administrativas, instalaciones de servicio y terminales del recinto portuario.

El plan maestro debe establecer la red principal de colectores sanitarios, así como los posibles puntos de bombeo o tratamiento requeridos para su funcionamiento. Este sistema debe mantenerse completamente separado del drenaje pluvial para evitar problemas operativos y ambientales.

Las terminales concesionadas deberán desarrollar sus redes internas de drenaje sanitario y conectarlas al sistema troncal en los puntos definidos por el plan maestro.

3.1.2.7 Red de telecomunicaciones y fibra óptica.

La red de telecomunicaciones constituye el sistema de conectividad que permite integrar las funciones de control, seguridad y operación del recinto portuario. Este sistema incluye la infraestructura de ductería, fibra óptica y nodos de telecomunicaciones necesarios para soportar servicios de transmisión de datos, videovigilancia, control de accesos y comunicaciones operativas.

El plan maestro debe establecer un backbone[1] de telecomunicaciones que recorra el puerto y que permita la conexión de los distintos nodos del sistema, incluyendo el centro de control, los accesos principales, las áreas administrativas y las terminales.

Cada cesionario podrá desarrollar su propia red interna de telecomunicaciones dentro de su terminal, pero deberá conectarse al sistema troncal del puerto en los puntos designados.

3.1.3 Evaluación de la matriz

La matriz no debe entenderse como una simple lista de instalaciones. En realidad, funciona como una herramienta de estructuración técnica del proyecto, porque permite distinguir qué sistemas deben ser concebidos como infraestructura común, qué elementos corresponden a cada cesionario, cómo debe organizarse el crecimiento por etapas y cuáles son los nodos que deben reservarse o definirse desde la planeación base. En proyectos portuarios de gran escala, esta diferenciación es indispensable para evitar vacíos de alcance, duplicidad de obras, conflictos entre infraestructuras y soluciones improvisadas en fases posteriores.

[1] Un backbone (red troncal o columna vertebral) es la infraestructura central de alta velocidad que interconecta redes más pequeñas, transportando grandes volúmenes de datos a través de países o continentes. Utiliza fibra óptica y enrutadores de gran capacidad para asegurar el tráfico rápido, eficiente y fiable entre diferentes áreas geográficas o dentro de redes locales

Tabla 3.1 Matriz Base para Planteamiento de Redes Principales.

Sistema / infraestructura	Alcance del proyecto maestro	Alcance del cesionario	Etapa 1	Etapa 2	Nodos / elementos principales requeridos	Observaciones técnicas
Red eléctrica principal	Definir fuente de alimentación, interconexión con CFE, subestación principal, corredores de media tensión, canalizaciones troncales y puntos de entrega a terminales	Red interna de distribución en baja/media tensión dentro de cada terminal, centros de carga, equipos y alumbrado propio	Debe quedar resuelta la alimentación troncal inicial y capacidad reservada para crecimiento	Ampliación de capacidad, nuevos ramales y refuerzo del sistema general	Punto de interconexión CFE, subestación principal, subestaciones auxiliares, ductos/bancos de ductos, registros, puntos de entrega	Tema crítico por la presencia/reubicación de torres de CFE; conviene diseñar desde inicio con capacidad de expansión
Alumbrado exterior común	Alumbrado de vialidades principales, accesos, patios comunes, zonas administrativas y áreas exteriores comunes	Alumbrado interior de patios, edificios y zonas operativas de cada terminal	Debe incluir accesos, vialidades y zonas comunes operativas	Extensión del sistema a nuevas áreas y refuerzo de niveles de iluminación	Postes, canalización, tableros, circuitos, centros de control	Debe coordinarse con red eléctrica y criterios de seguridad portuaria
Agua potable / agua de servicios	Definir fuente, línea principal, almacenamiento, regulación y red troncal con puntos de entrega a terminales y áreas comunes	Distribución interna dentro de terminales, edificios propios y consumos operativos particulares	Debe resolverse la fuente y red primaria para zona administrativa, servicios y primeras terminales	Incremento de capacidad, anillos y nuevas derivaciones	Punto de abastecimiento, tanque/cisterna, estaciones de bombeo, red primaria, válvulas, macromedición, puntos de entrega	Conviene separar consumo común y consumo por cesionario desde el planteamiento conceptual
Red contra incendio maestra	Reserva de agua, cuarto de bombas, red troncal o anillo principal en áreas comunes y puntos de conexión a terminales	Red contra incendio interna de terminales, edificios y patios concesionados	Debe dejarse prevista desde el inicio, al menos en corredores troncales y zonas comunes	Ampliación del anillo y refuerzo de cobertura	Tanque contra incendio, casa de bombas, anillo troncal, hidrantes exteriores, válvulas seccionales, conexiones a terminales	Sistema prioritario; no debe posponerse si condiciona la operación segura del conjunto
Drenaje pluvial maestro	Definir pendientes generales, colectores principales, obras de conducción, regulación y descarga del desarrollo completo	Drenaje interno de patios/edificios de cada terminal hasta su punto de conexión	Debe resolverse estructuralmente desde etapa 1 por plataformas, vialidades y condicionantes lagunares	Ampliación de colectores, obras complementarias y refuerzo de control hidráulico	Colectores troncales, cunetas/canales, rejillas, bocas de tormenta, cárcamos, descargas, estructuras de control	Uno de los sistemas más críticos por topografía baja, mareas y gran superficie impermeable futura
Drenaje sanitario troncal	Red sanitaria principal, colectores, estaciones de bombeo y tratamiento o punto de descarga general	Redes sanitarias internas de terminales y edificios concesionados hasta punto de conexión	Debe quedar resuelta para zona administrativa, servicios comunes y primeros desarrollos	Extensión de red y crecimiento de capacidad	Colectores, pozos de visita, cárcamos, línea de impulsión, planta de tratamiento o punto de entrega	Debe quedar claramente separado del sistema pluvial
Telecomunicaciones / fibra óptica	Ductería troncal, backbone de comunicaciones, red de fibra principal, puntos de interconexión y soporte para sistemas comunes	Redes internas de datos, voz, automatización y control dentro de cada terminal	Debe implementarse backbone inicial y ductos troncales principales	Ampliación a nuevas terminales y redundancia	Ductos, registros, nodos de telecom, fibra óptica, cuartos técnicos, puntos de entrega	Conviene dejar reserva de ductos para crecimiento futuro
Centro de control y monitoreo	Definir edificio o nodo maestro de control, seguridad, monitoreo y coordinación operativa del puerto en áreas comunes	Centros de control internos del cesionario, integrables o no con el sistema maestro	Debe quedar previsto al menos conceptualmente y con espacio reservado	Consolidación operativa al crecer el puerto	Centro de control, salas de monitoreo, enlaces de telecom, respaldo eléctrico	Puede integrar CCTV, accesos, comunicaciones y coordinación operativa
Control de accesos y seguridad perimetral	Accesos generales, filtros, casetas, CCTV común, cercado/perímetro del desarrollo maestro	Controles internos de acceso en terminales concesionadas	Debe resolverse en accesos principales desde etapa 1	Ampliación de filtros, cobertura CCTV y áreas nuevas	Casetas, carriles de inspección, barreras, CCTV, cercado, lectores y sistemas	Debe coordinarse con vialidades, estacionamientos y logística de tractocamiones
Vialidades con corredor de utilidades	Diseño de vialidades principales incorporando franjas o corredores para redes maestras	Adecuaciones internas en terminales a partir del punto de entrega	Deben quedar reservados desde la etapa 1	Continuidad y expansión hacia nuevas zonas	Derecho de vía, franjas técnicas, cruces, ductos, registros, servidumbres	Es clave que las vialidades funcionen también como soporte de utilidades
Cruces y corredores ferroviarios con redes	Coordinar cruces de redes maestras con infraestructura ferroviaria y vial del puerto	Cruces internos dentro de la terminal, si aplican	Deben resolverse desde el diseño base	Se amplían conforme crece el sistema ferroviario	Cruces protegidos, camisas, pasos técnicos, registros especiales	Evita interferencias futuras y sobrecostos por relocalización
Zona administrativa y de servicios comunes	Proveer servicios troncales, accesibilidad, drenajes, energía y telecomunicaciones para edificios comunes	Equipamiento interno de edificios específicos del cesionario	Debe quedar operativa en etapa 1	Se amplía según crecimiento del puerto	Nodo hidráulico, sanitario, eléctrico y telecom	Conviene identificarla como uno de los primeros nodos de servicios
Estacionamiento de tractocamiones y áreas de apoyo	Dotar de servicios principales, drenaje, alumbrado, control y abastecimiento básico	Equipamientos complementarios si alguna terminal integra áreas propias	Debe entrar en etapa 1 por impacto operativo	Ampliación o refuerzo por demanda	Alumbrado, agua, sanitario, pluvial, telecom, control de accesos	Es parte del sistema logístico común, no solo un accesorio
Ayudas a la operación marítima / control marítimo	Reserva de espacio e integración con sistemas de control y telecom del puerto, en su caso	Equipamiento específico terminal-marítimo si aplica al operador	Puede quedar como previsión o nodo reservado	Mayor desarrollo conforme aumente complejidad operativa	Edificio/nodo, telecom, energía, enlaces	No necesariamente debe detallarse a nivel de edificio final, pero sí reservarse e identificarse
Manejo de residuos y servicios ambientales comunes	Áreas comunes y red/base de manejo ambiental general fuera de terminales	Manejo interno de residuos propios del cesionario	Debe quedar prevista la infraestructura mínima común	Consolidación y especialización por crecimiento	Área de residuos, drenajes controlados, servicios básicos	Relevante por el entorno lagunar y criterios ambientales
Interfases puerto–terminal	Definir en plano y memoria los puntos oficiales de entrega de cada servicio	Recibir y continuar la red dentro de la terminal	Deben quedar definidos desde etapa 1	Se replican y ajustan para nuevas terminales	Punto de entrega eléctrico, hidráulico, sanitario, pluvial y telecom	Esta fila es clave para delimitar responsabilidades y evitar vacíos de alcance

Fuente: Elaboración propia, 2026

a. La red eléctrica principal constituye el primer sistema estructurante porque toda la operación del desarrollo dependerá de ella, tanto en áreas comunes como en los puntos de entrega a terminales.

   Desde el punto de vista técnico, la red eléctrica del plan maestro no se limita a “llevar energía al sitio”, sino que debe organizar la arquitectura general del abastecimiento. Esto implica definir el punto de interconexión con la infraestructura regional, prever la interfase con CFE, establecer la necesidad de una subestación principal y, en su caso, subestaciones o nodos seccionales, además de los corredores de media tensión y las canalizaciones que recorrerán el desarrollo.

   La razón por la cual esta red debe ser resuelta por el plan maestro es que la energía no puede distribuirse de manera ordenada si cada terminal parte de soluciones aisladas o toma decisiones independientes sobre su acometida principal. La estructura lineal del proyecto hace aún más evidente la necesidad de una espina dorsal eléctrica longitudinal que permita abastecer secuencialmente las áreas comunes y, después, dejar puntos de entrega hacia las terminales. Al cesionario le corresponderá la distribución interna dentro de su predio, incluyendo transformación final, tableros, centros de carga, alumbrado propio y energía para equipos operativos.

   Sin embargo, nada de ello podrá funcionar adecuadamente si no existe una infraestructura troncal que garantice continuidad, capacidad suficiente y posibilidad de expansión hacia la segunda etapa. El alumbrado exterior común, la videovigilancia, el centro de control y las instalaciones de acceso dependen también de esta red, por lo que su definición temprana es fundamental.

b. El alumbrado exterior común debe entenderse como un sistema propio de la infraestructura general del puerto y no como una extensión menor de la red eléctrica.

   Técnicamente, su función no se agota en proporcionar visibilidad; forma parte de la seguridad operacional, del control perimetral, de la circulación segura en horario nocturno y de la reducción de riesgos en vialidades, accesos, glorietas, viaductos, estacionamientos y zonas administrativas. En un recinto portuario como el que se plantea, la iluminación de las áreas comunes no puede quedar sujeta a decisiones particulares de cada concesionario, porque las vialidades y espacios de transición sirven al sistema completo y deben mantener continuidad funcional entre una terminal y otra.

   Por ello, el plan maestro debe prever postes, canalizaciones, alimentación, centros de control y criterios de cobertura para todas las áreas compartidas. Al cesionario le corresponderá iluminar sus patios, edificios, muelles concesionados y áreas interiores,

pero la iluminación de la estructura común del puerto debe emanar de una red maestra planificada desde el inicio. Esto es particularmente importante en la Etapa 1, ya que es ahí donde se forman las condiciones básicas de accesibilidad y seguridad que deberán mantenerse cuando el sistema crezca en la Etapa 2.

c. La red de agua potable y agua de servicios representa otro sistema troncal que debe ser organizado por el plan maestro.

   En términos técnicos, la red no solo debe abastecer agua para consumo humano, sino también agua para servicios generales, limpieza, edificios comunes, áreas de apoyo y, eventualmente, algunos usos operativos que queden fuera de la responsabilidad de los cesionarios.

   La razón por la cual esta red debe ser prevista desde la planeación maestra es que el abastecimiento hidráulico del puerto no puede depender de soluciones dispersas, tomas independientes o pequeños sistemas aislados por terminal. La infraestructura común debe definir la fuente de abastecimiento, el punto de conexión con la red exterior, la necesidad de almacenamiento y regulación, las líneas principales de conducción, la sectorización y los puntos de entrega. Si esto no se hace desde el principio, la consecuencia habitual es la proliferación de tuberías desordenadas, pérdida de presión, falta de control de consumos y ocupación ineficiente de los corredores de servicios.

   En el proyecto cuya configuración es esencialmente longitudinal, la lógica técnica más consistente es que la conducción principal recorra la franja interior del desarrollo, alimentando primero la zona administrativa y de servicios, luego las áreas comunes y finalmente los puntos de entrega a las terminales. Cada cesionario desarrollará a partir de ahí su red interior de distribución. Lo importante es que el puerto defina desde ahora la arquitectura general del suministro y deje previstas las reservas de capacidad para la ampliación posterior.

d. La red contra incendio maestra es uno de los sistemas más delicados desde la perspectiva de seguridad y, por tanto, uno de los que más claramente deben ser resueltos por el plan maestro.

   En un desarrollo portuario de la escala planteada, no es técnicamente aceptable que la protección contra incendio de las áreas comunes dependa exclusivamente de redes privadas o de soluciones internas de terminales aisladas. El puerto debe disponer de una infraestructura general de respuesta que proteja los accesos, las vialidades, la zona administrativa, los espacios de regulación del autotransporte, los corredores comunes y los puntos de conexión con terminales. Esto implica prever una reserva de agua, un cuarto o casa de bombas, un anillo o troncal principal, hidrantes exteriores,

válvulas seccionales y puntos de enlace con las futuras terminales. El cesionario será responsable de sus sistemas interiores especializados, tales como rociadores, monitores, redes de hidrantes internas o sistemas específicos para sus propias áreas de riesgo, pero la estructura general del recinto requiere un soporte común que forme parte del plan maestro.

Desde el punto de vista técnico, esta red debe coordinarse con la red de agua de servicios, con la accesibilidad de vehículos de emergencia y con la sectorización del desarrollo. Además, al igual que los demás sistemas, no puede ser vista como una infraestructura secundaria: debe plantearse desde la Etapa 1 con capacidad suficiente para el arranque y con criterios de expansión para la Etapa 2.

e. El drenaje pluvial maestro es probablemente uno de los sistemas más sensibles del proyecto por la localización en la Laguna de Cuyutlán, la previsión de grandes superficies impermeables y la necesidad de operar de manera confiable incluso bajo eventos intensos de lluvia y posibles condicionantes de nivel lagunar o de marea.

   Técnicamente, el drenaje pluvial no puede resolverse por fragmentos ni dejarse a decisión de cada terminal, porque depende de la topografía general, de las rasantes del proyecto, de la configuración de plataformas, de la ubicación de vialidades y de la interacción entre todas las superficies aportantes del conjunto. El plan maestro debe, por tanto, definir la lógica completa del escurrimiento del puerto, estableciendo pendientes generales, colectores longitudinales, puntos de captación, obras de cruce, estructuras de regulación, posibles cárcamos y descargas controladas.

   La primera etapa debe resolver por completo el comportamiento hidráulico del ámbito inicial, pero al mismo tiempo debe hacerlo de manera compatible con el crecimiento de la segunda etapa. Si esto no se prevé desde el comienzo, la ampliación futura podría obligar a rehacer colectores, modificar rasantes o aceptar encharcamientos y fallas funcionales en áreas críticas. El cesionario resolverá el drenaje interno de sus patios y edificios, pero siempre deberá conectarse a un sistema maestro que ya haya definido criterios de capacidad, ubicación y descarga.

   En este tipo de proyectos, el drenaje pluvial no es un complemento de la urbanización; es una condición estructural de viabilidad operativa y ambiental.

f. El drenaje sanitario troncal debe entenderse como el sistema general que recoge y conduce las aguas residuales de las áreas comunes del recinto y, posteriormente, las aportaciones provenientes de las terminales a través de puntos de conexión definidos.

   A diferencia del drenaje pluvial, cuyo comportamiento está estrechamente ligado a la conformación superficial del territorio, el sistema sanitario se vincula con edificios,

servicios al personal, estacionamientos, áreas administrativas y futuras descargas internas de cada terminal. No obstante, ello no reduce su importancia como infraestructura troncal. El plan maestro debe definir colectores principales, pozos de visita, posibles estaciones de bombeo, impulsiones y la solución final de tratamiento o punto de disposición.

En este caso, la claridad conceptual es especialmente importante porque el drenaje sanitario debe mantenerse totalmente separado del drenaje pluvial, tanto en la planeación como en la ejecución posterior. La falta de definición temprana suele conducir a mezclas indebidas, sobrecargas en el sistema, problemas ambientales y costos adicionales. Cada cesionario diseñará su red interior sanitaria, pero deberá contar con un punto claro de entrega o incorporación al sistema común. Por ello, la responsabilidad del plan maestro es establecer la traza general, la capacidad prevista por etapas y la forma en que la segunda fase se incorporará a la infraestructura inicialmente construida.

g. La red de telecomunicaciones y fibra óptica debe tratarse como un servicio estructural y no como un simple componente auxiliar.

   La operación moderna de un puerto depende en gran medida de la conectividad de datos, de la videovigilancia, del control de accesos, de la comunicación operativa y de la capacidad de integrar distintos sistemas en una sola arquitectura tecnológica. En ese sentido, el plan maestro debe prever la ductería troncal, los registros, los nodos de telecomunicaciones, el backbone de fibra óptica y los puntos de enlace con las terminales.

   No resulta técnicamente conveniente dejar que cada cesionario tienda sus propias infraestructuras de comunicación a través del recinto, porque ello produciría desorden físico, falta de interoperabilidad, ocupación innecesaria de corredores y dificultades de integración con los sistemas de control del puerto. La lógica más consistente es que el backbone recorra la misma franja longitudinal que las demás redes principales, enlazando el acceso general, la zona administrativa, el centro de control, las áreas comunes y los puntos de conexión con las terminales.

   En la primera etapa deberá quedar resuelta la infraestructura base y previstas las reservas de ductería y capacidad para la segunda etapa. El cesionario desplegará a partir de esa interfase sus redes internas de datos, automatización o comunicaciones operativas, pero la plataforma común debe nacer del plan maestro.

h. El centro de control y monitoreo es un nodo funcional que sintetiza la necesidad del puerto de operar como sistema integrado. No se trata solamente de una edificación o

de una sala de videowall; es la pieza donde convergen la seguridad, el monitoreo, la coordinación de accesos, la supervisión de áreas comunes y la respuesta a incidentes.

La razón técnica para incluirlo en la matriz y asignarlo al plan maestro es que ninguna terminal, por sí sola, puede asumir la gobernanza de los espacios compartidos del recinto. El centro de control debe ubicarse en una posición estratégica respecto del acceso general, de la zona administrativa y del nodo principal de telecomunicaciones, de forma que pueda supervisar el conjunto.

Desde el punto de vista del diseño, lo importante en esta fase no es resolver en detalle su arquitectura, sino reservar su localización, garantizar su conectividad y asegurar que reciba alimentación eléctrica y de datos suficiente. En la primera etapa conviene habilitar al menos su versión inicial, escalable, y en la segunda consolidarlo como nodo completo de coordinación. Los cesionarios podrán tener sus propios centros de control internos, pero la operación del sistema común del puerto exige una instalación rectora bajo el ámbito del plan maestro.

i. El control de accesos y la seguridad perimetral forman parte de la infraestructura básica del recinto y no pueden dejarse como consecuencia espontánea de la operación terminal por terminal.

   Técnicamente, el acceso principal al puerto, las casetas, los carriles de revisión, las barreras, el cercado perimetral, la iluminación de seguridad y la cobertura de CCTV constituyen la frontera operativa del proyecto. Su papel es ordenar el ingreso y egreso del sistema completo antes de que el tránsito se disperse hacia las distintas terminales. Esto es particularmente importante en un puerto ampliado con alto movimiento de camiones, personal, proveedores y operaciones logísticas. Si la gobernanza del acceso se fragmenta, se pierde trazabilidad, se multiplican puntos vulnerables y disminuye la eficiencia del sistema.

   Por ello, el plan maestro debe definir la ubicación, capacidad y funcionamiento de los accesos generales desde la primera etapa, incluyendo su coordinación con el estacionamiento de tractocamiones y las vialidades principales. Los cesionarios asumirán el control interno de sus predios, pero la puerta de entrada al sistema debe mantenerse como responsabilidad común y centralizada.

j. Las vialidades con corredor de utilidades representan un criterio de diseño de enorme importancia, porque en realidad articulan físicamente la mayor parte de las redes anteriores.

   La matriz las incluye no como una red independiente, sino como la estrategia espacial para alojar ordenadamente la infraestructura troncal. En proyectos lineales como el

que se revisa, las vialidades principales deben diseñarse simultáneamente como vías de circulación y como soporte de ductos, tuberías, cables y registros.

Técnicamente, esto significa reservar desde el plan maestro una franja de utilidades continua, asociada al eje vial principal, dentro de la cual puedan organizarse la red eléctrica, la red de agua, la red contra incendio, el backbone de telecomunicaciones y, donde resulte adecuado, ciertas conducciones de drenaje. La ventaja de este enfoque es clara: reduce interferencias, facilita construcción y mantenimiento, da legibilidad al sistema y, sobre todo, permite que la primera etapa deje instalada la base física para que la segunda solo prolongue el corredor sin alterar lo ya construido.

Si esto no se considera desde el inicio, la ampliación futura suele traducirse en apertura de pavimentos, invasión de zonas operativas y soluciones técnicas poco elegantes y costosas.

k. Los cruces y corredores ferroviarios con redes constituyen un tema específico, pero crítico, debido a la presencia del sistema ferroviario como parte estructurante del proyecto. Toda red troncal que deba cruzar o acompañar la infraestructura ferroviaria necesita una coordinación anticipada, porque no es admisible resolver esas interfases de manera improvisada en obra.

   Técnicamente, ello implica prever camisas, pasos técnicos, distancias de seguridad, registros especiales y localizaciones muy claras de los cruces indispensables. El plan maestro debe identificar desde la planeación dónde las redes irán paralelas a las vías y dónde se concentrarán los cruces transversales. Esta definición es su responsabilidad, porque depende de la configuración territorial global del puerto y no de las necesidades particulares de una terminal. El cesionario resolverá sus cruces internos dentro de su propio lote si los requiere, pero la coexistencia entre utilidades comunes y ferrocarril en el recinto portuario solo puede ser ordenada desde el plan maestro.

   En la práctica, una buena definición temprana de estos cruces evita interferencias, costos extraordinarios y riesgos para la operación.

l. La zona administrativa y de servicios comunes aparece en la matriz porque, aunque a veces se la perciba como una pieza secundaria frente a los muelles o las terminales, en realidad funciona como uno de los nodos de mayor importancia para la infraestructura común. Ahí se concentran oficinas generales, servicios al personal, áreas de apoyo, posibles instalaciones de atención al transportista y espacios que forman parte del soporte operativo del recinto pero que no pertenecen a ninguna terminal en particular.

Desde el punto de vista técnico, esta zona debe ser uno de los primeros puntos servidos por las redes del plan maestro y, de hecho, puede convertirse en el ancla de la primera etapa para varios sistemas, energía, agua, drenaje, telecomunicaciones, seguridad y accesibilidad deben llegar a este nodo desde el inicio.

El cesionario resolverá solo sus áreas administrativas internas si así lo requiere, pero la existencia de una zona administrativa común fortalece la coherencia operativa del puerto y debe ser tratada como parte esencial del sistema estructurante.

m. El estacionamiento de tractocamiones y las áreas de apoyo también integran la matriz porque cumplen una función logística común imprescindible. En puertos de esta naturaleza, estas áreas regulan flujos, disminuyen saturación en los accesos, permiten ordenar tiempos de espera y sirven de soporte al sistema terrestre completo.

   Técnicamente, no basta con reservarles espacio; deben contar con alumbrado, drenaje pluvial, agua, servicios sanitarios, telecomunicaciones, control de acceso y conectividad con las vialidades principales. Si esta infraestructura no se incluye en el plan maestro, el resultado suele ser la aparición de zonas improvisadas de espera o regulación, con efectos negativos sobre seguridad y eficiencia logística.

   Por ello, la primera etapa debe contemplar este nodo como parte integrante del sistema, y la segunda deberá ampliarlo o reforzarlo según lo demande el crecimiento operativo.

n. Las ayudas a la operación y el control marítimos se incorporan en la matriz como un sistema que, aunque pueda no estar completamente definido en su detalle arquitectónico o institucional, sí debe ser reconocido por el plan maestro como una necesidad funcional futura.

   A medida que el puerto crezca y aumente la complejidad de maniobras, accesos náuticos y coordinación de la operación, será necesario contar con espacios, conectividad y servicios compatibles con esas funciones. No necesariamente significa que el plan maestro deba diseñar en esta fase una torre definitiva o un centro marítimo completo, pero sí implica que debe reservar espacio, prever la llegada de energía y telecomunicaciones y asegurar la compatibilidad de su localización con la operación del conjunto. De lo contrario, la expansión portuaria podría terminar sin espacio adecuado para incorporar estas funciones, obligando a soluciones forzadas o poco eficientes.

o. El manejo de residuos y los servicios ambientales comunes tienen una importancia particular en este proyecto por el entorno lagunar de la Laguna de Cuyutlán. La matriz los incluye porque el plan maestro no puede limitarse a conducir utilidades

tradicionales; también debe prever la infraestructura común mínima necesaria para gestionar residuos, escurrimientos potencialmente contaminados en áreas no concesionadas y servicios ambientales básicos del recinto.

Técnicamente, esto significa reservar áreas para acopio temporal, prever condiciones de abastecimiento y drenaje controlado en ciertas zonas comunes y garantizar que la operación exterior a las terminales mantenga criterios compatibles con el contexto ambiental sensible. Cada cesionario será responsable de sus residuos y de sus medidas internas, pero el sistema portuario compartido debe contar con una base ambiental común. Esto no solo responde a criterios regulatorios, sino a la lógica de proteger un medio receptor especialmente delicado.

p. Finalmente, las interfases puerto-terminal son probablemente el punto más importante de toda la matriz, porque en ellas se define con precisión dónde termina la responsabilidad del plan maestro y dónde comienza la del cesionario.

Técnicamente, una interfase no es una idea abstracta; es un punto físico de entrega o conexión para cada servicio. Debe establecerse dónde se entrega la energía, dónde se entrega el agua, cómo se conecta la red contra incendio, en qué punto se incorporan los drenajes sanitarios y pluviales y desde qué registro o nodo se enlazan las telecomunicaciones. Si estas interfases no se definen con claridad, aparecen vacíos de alcance, controversias contractuales, incompatibilidades de diseño y retrasos en la implantación de las terminales. Por ello, la matriz incluye este rubro de forma expresa.

La responsabilidad del plan maestro es fijar esos puntos y garantizar sus condiciones de capacidad, localización y operación. A partir de ellos, el cesionario continuará la red dentro de su predio. En un proyecto por etapas como este, la claridad de las interfases es lo que permitirá que la expansión futura se produzca sin pérdida de coherencia ni conflictos entre partes.

En conjunto, la matriz demuestra que el plan maestro no debe limitarse a definir superficies terminales y corredores de transporte, sino que debe crear el esqueleto funcional completo del puerto ampliado. Esa es, en realidad, la razón de ser de la infraestructura troncal: permitir que el desarrollo crezca como un sistema ordenado, ampliable y técnicamente coherente.

La primera etapa debe construir esa base y la segunda debe apoyarse en ella para prolongarla, reforzarla y consolidarla. Esa lógica aplica especialmente a la red eléctrica, a la red de agua, a la red contra incendio, al drenaje pluvial maestro, al drenaje sanitario, al backbone de telecomunicaciones y a las interfases con terminales, que son los elementos más estratégicos de la matriz y los que, en conjunto, condicionarán la solidez técnica del proyecto.

3.2 Criterios de Ingeniería para el Planteamiento de Redes.

El plan maestro del Puerto de Manzanillo en la Laguna de Cuyutlán deberá establecer la infraestructura troncal necesaria para habilitar la operación integral del recinto portuario. Esta infraestructura estará conformada por las redes principales de servicios, los nodos de infraestructura y los corredores de utilidades que permitirán la conexión de las terminales concesionadas.

El desarrollo de dichas redes deberá realizarse con una visión de largo plazo, considerando la capacidad requerida para el desarrollo completo del puerto y no únicamente para la etapa inicial. La planeación deberá garantizar que la infraestructura construida en la primera etapa sea compatible con las ampliaciones previstas para etapas posteriores.

El plan maestro tendrá la responsabilidad de definir los corredores de infraestructura, los nodos principales de cada sistema y los puntos de entrega hacia las terminales. A partir de estos puntos, cada cesionario desarrollará las redes internas de su terminal de acuerdo con sus necesidades operativas.

Por lo tanto, el planteamiento de las redes de servicios principales dentro del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán debe desarrollarse bajo criterios de ingeniería que garanticen confiabilidad operativa, escalabilidad, seguridad, facilidad de mantenimiento e integración con la infraestructura portuaria existente y futura. La definición de estas redes no debe limitarse únicamente a la cobertura de las necesidades inmediatas del proyecto, sino que debe considerar el desarrollo progresivo del recinto portuario, la incorporación de nuevas terminales y la interacción con los sistemas logísticos terrestres y marítimos que conforman el sistema portuario.

Desde el punto de vista técnico, el diseño de estas redes debe apoyarse en estándares reconocidos a nivel nacional e internacional, entre los cuales destacan las Normas Oficiales Mexicanas (NOM), los manuales de diseño de la Comisión Federal de Electricidad (CFE), los lineamientos de la Comisión Nacional del Agua (CONAGUA), las normas de la National Fire Protection Association (NFPA) para sistemas contra incendio, así como las recomendaciones contenidas en guías técnicas de infraestructura portuaria desarrolladas por organismos como PIANC (World Association for Waterborne Transport Infrastructure) y AASHTO para infraestructura logística y de transporte.

Asimismo, el planteamiento de las redes debe considerar las características particulares del sitio, especialmente su condición de entorno lagunar con cotas topográficas bajas, la proximidad con el mar, la presencia de suelos blandos típicos de ambientes costeros y la necesidad de mantener condiciones adecuadas de drenaje y estabilidad hidráulica.

La adecuada planificación de estas redes permitirá garantizar la operación eficiente del puerto, optimizar el uso del espacio disponible y evitar interferencias entre infraestructuras. Asimismo, facilitará la integración de nuevas terminales conforme el puerto se expanda.

3.2.1 Red eléctrica

El sistema de suministro eléctrico del recinto portuario debe diseñarse como una red jerárquica estructurada a partir de una subestación principal de transformación que reciba energía desde la red regional de transmisión o subtransmisión de la Comisión Federal de Electricidad. A partir de este punto de interconexión se debe desarrollar una red de distribución en media tensión que recorra longitudinalmente el puerto a través de corredores de infraestructura ubicados preferentemente en las franjas técnicas de las vialidades principales.

La planificación de esta red debe seguir los criterios establecidos en el Manual de Distribución de la Comisión Federal de Electricidad, particularmente en lo referente al dimensionamiento de alimentadores, niveles de tensión, esquemas de protección y confiabilidad del sistema. En desarrollos portuarios de gran escala se recomienda la utilización de configuraciones en anillo o redes malladas que permitan mantener la continuidad del servicio ante fallas o mantenimientos programados.

La capacidad de la subestación principal debe dimensionarse considerando no solamente la demanda eléctrica inicial de las primeras terminales, sino también la demanda proyectada para el desarrollo completo del puerto. Este enfoque responde a los principios de ingeniería de sistemas eléctricos industriales, en los cuales se busca evitar ampliaciones estructurales de gran magnitud en etapas posteriores del proyecto.

Las terminales concesionadas deberán recibir el suministro eléctrico a través de puntos de entrega definidos en la red troncal y desarrollar sus propias redes internas de distribución conforme a sus requerimientos operativos, incluyendo centros de transformación, subestaciones internas y sistemas de alimentación para grúas portuarias, patios de contenedores y equipos especializados.

3.2.2 Red de agua potable y servicios

El sistema de abastecimiento de agua del recinto portuario debe diseñarse con base en principios de ingeniería hidráulica que aseguren disponibilidad continua del recurso, estabilidad de presión en la red y capacidad suficiente para cubrir las demandas operativas y de servicios del puerto.

La fuente de abastecimiento puede provenir de redes municipales, pozos autorizados o sistemas regionales de suministro, dependiendo de la disponibilidad local del recurso. En cualquier caso, el diseño debe cumplir con los lineamientos establecidos en la Norma Oficial Mexicana

NOM-127-SSA1, referente a la calidad del agua para uso y consumo humano, así como con los criterios técnicos de diseño de redes de distribución establecidos por la CONAGUA.

La infraestructura del sistema debe incluir elementos de almacenamiento y regulación hidráulica, tales como tanques elevados o cisternas de gran capacidad, que permitan estabilizar la presión de la red y garantizar el suministro en caso de interrupciones temporales del abastecimiento externo. Desde estos nodos hidráulicos se debe desarrollar una red de distribución principal que siga el eje longitudinal del puerto y que permita derivaciones hacia las áreas administrativas, las zonas logísticas y las terminales portuarias.

El diseño hidráulico debe considerar pérdidas de carga, velocidad del flujo, sectorización del sistema y la posibilidad de aislar tramos de la red para mantenimiento sin afectar la operación general del recinto.

3.2.3 Red contra incendio

La red contra incendio del puerto debe concebirse como un sistema independiente del suministro de agua potable, diseñado específicamente para garantizar la disponibilidad de caudales y presiones adecuados en situaciones de emergencia. Este sistema debe cumplir con los lineamientos establecidos en normas internacionales como NFPA 24 (Standard for the Installation of Private Fire Service Mains) y NFPA 13 (Standard for the Installation of Sprinkler Systems), las cuales son ampliamente utilizadas en instalaciones industriales y portuarias.

El sistema debe incluir un tanque de almacenamiento exclusivo para protección contra incendios, así como una casa de bombas equipada con bombas principales, bombas de reserva y bombas jockey que mantengan la presión constante en la red. Desde este punto se debe desarrollar una red troncal de tuberías que cubra las áreas comunes del recinto portuario y que permita la instalación de hidrantes en puntos estratégicos.

La ubicación de estos hidrantes debe considerar distancias de cobertura adecuadas para la operación de equipos de combate contra incendios, así como la proximidad a áreas de riesgo potencial, tales como zonas de almacenamiento de combustibles o terminales especializadas.

Las terminales concesionadas deberán instalar sus propios sistemas internos de protección contra incendio, los cuales deberán ser compatibles hidráulicamente con la red maestra del puerto.

3.2.4 Drenaje pluvial

El sistema de drenaje pluvial del proyecto debe diseñarse considerando las características hidrológicas y topográficas del sitio, así como los eventos de precipitación característicos de la región. En este sentido, el dimensionamiento de colectores y estructuras de captación debe

basarse en análisis hidrológicos que consideren periodos de retorno apropiados para infraestructura crítica, generalmente entre 25 y 50 años.

El diseño del sistema debe seguir los lineamientos establecidos en los manuales de drenaje urbano de CONAGUA, así como las metodologías de cálculo hidrológico utilizadas en proyectos de infraestructura mayor. En áreas portuarias es fundamental considerar la gran extensión de superficies impermeables, tales como patios de contenedores y plataformas logísticas, las cuales generan escurrimientos significativos durante eventos de lluvia intensa.

El sistema pluvial debe estructurarse mediante colectores principales que conduzcan el agua hacia puntos de descarga controlados dentro del sistema lagunar o hacia estructuras de regulación hidráulica. En zonas con cotas topográficas bajas, como es el caso de la Laguna de Cuyutlán, puede ser necesario incorporar estaciones de bombeo pluvial para asegurar la evacuación del agua durante mareas altas o eventos extremos.

3.2.5 Drenaje sanitario

El sistema de drenaje sanitario debe diseñarse como una red independiente del drenaje pluvial, de acuerdo con los principios básicos de ingeniería sanitaria. Esta separación permite evitar la sobrecarga de las instalaciones de tratamiento y reducir el riesgo de contaminación ambiental.

El diseño de esta red debe seguir los criterios establecidos en las normas y manuales de CONAGUA para sistemas de alcantarillado sanitario, los cuales establecen parámetros para el cálculo de caudales, pendientes mínimas de tuberías, diámetros recomendados y espaciamiento de pozos de visita.

La red sanitaria troncal debe conducir las aguas residuales generadas en las áreas administrativas, edificios de servicios y terminales hacia un punto de tratamiento o disposición final autorizado. Dependiendo de la configuración topográfica del sitio, puede ser necesario incorporar cárcamos de bombeo sanitario que permitan elevar el flujo hacia colectores principales o plantas de tratamiento.

3.2.6 Telecomunicaciones

La red de telecomunicaciones del puerto constituye una infraestructura crítica para la operación logística y de seguridad del recinto. Este sistema debe diseñarse a partir de un backbone de fibra óptica que recorra el puerto a lo largo de los corredores de utilidades y que conecte los principales nodos operativos del sistema portuario.

Entre estos nodos se incluyen el centro de control portuario, los accesos principales, las áreas administrativas, las instalaciones de seguridad y las terminales concesionadas. El diseño de

esta red debe considerar redundancia en las rutas de fibra óptica para garantizar la continuidad de las comunicaciones en caso de fallas o cortes accidentales.

Asimismo, la infraestructura de telecomunicaciones debe incluir ductos, registros y cámaras de inspección que permitan la instalación y mantenimiento de cables de fibra óptica, así como la posible expansión futura del sistema.

3.3 Integración de redes en corredores de utilidades.

Un criterio fundamental en el diseño de redes dentro de desarrollos portuarios consiste en la organización de las distintas infraestructuras dentro de corredores de utilidades comunes. Estos corredores se ubican generalmente en las franjas técnicas de las vialidades principales y permiten concentrar en un mismo eje las redes eléctricas, hidráulicas, sanitarias y de telecomunicaciones.

La utilización de corredores de utilidades facilita la construcción, operación y mantenimiento de las redes, reduce interferencias entre infraestructuras y permite realizar ampliaciones futuras sin afectar las áreas operativas del puerto.

El planteamiento de las redes de servicios principales debe desarrollarse con una visión integral del sistema portuario, considerando tanto las necesidades operativas actuales como las condiciones de crecimiento futuro del recinto. La correcta planificación de estas infraestructuras permitirá asegurar la continuidad operativa del puerto, optimizar el uso del espacio disponible y garantizar la compatibilidad entre las distintas instalaciones que conforman el sistema logístico portuario.

3.4 Dimensionamiento preliminar de redes.

El dimensionamiento preliminar de las redes de servicios principales del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán debe realizarse considerando el desarrollo progresivo del recinto portuario y la naturaleza altamente intensiva en infraestructura de las operaciones portuarias modernas. Desde el punto de vista de la ingeniería, el dimensionamiento de estas redes debe responder a un enfoque de capacidad futura, en el cual los sistemas principales se diseñan para atender la demanda total prevista del puerto una vez que el desarrollo alcance su máxima ocupación operativa.

Este enfoque es particularmente importante en desarrollos portuarios, ya que la ampliación posterior de redes troncales suele implicar intervenciones complejas en áreas operativas, lo cual puede afectar la continuidad de las actividades logísticas. Por esta razón, la infraestructura principal debe concebirse como un sistema con capacidad estructural suficiente para absorber el crecimiento del proyecto.

3.4.1 Dimensionamiento Preliminar del Sistema Eléctrico.

El dimensionamiento del sistema eléctrico del puerto debe considerar las cargas típicas asociadas a las operaciones portuarias modernas, especialmente aquellas relacionadas con terminales de contenedores, las cuales demandan cantidades significativas de energía para la operación de grúas pórtico tipo STS, grúas RTG o RMG, equipos de manipulación de carga, sistemas de refrigeración de contenedores y edificios logísticos.

De acuerdo con experiencias internacionales y referencias de proyectos portuarios comparables, el consumo eléctrico de una terminal de contenedores puede variar entre 5 y 15 MW dependiendo del nivel de automatización y del volumen de operaciones. En el caso de un desarrollo portuario con múltiples terminales especializadas, el dimensionamiento de la subestación principal debe considerar la suma de las demandas máximas probables de las terminales, aplicando factores de simultaneidad adecuados para evitar sobredimensionamientos excesivos.

El sistema de distribución en media tensión debe diseñarse conforme a los criterios establecidos en el Manual de Distribución de la Comisión Federal de Electricidad, considerando tensiones típicas de operación de 13.8 kV o 23 kV, dependiendo de la configuración del sistema regional. Los alimentadores principales deben dimensionarse para transportar la demanda prevista del conjunto del puerto, considerando pérdidas de potencia, caída de tensión y condiciones de operación en régimen permanente y en contingencia.

Asimismo, el diseño del sistema debe prever la instalación de esquemas de protección, seccionamiento y redundancia que permitan mantener el suministro eléctrico en caso de fallas en algún tramo de la red.

3.4.2 Dimensionamiento Preliminar del Sistema de Agua Potable y de Servicios.

El dimensionamiento del sistema hidráulico del puerto debe considerar las demandas de agua asociadas tanto a las áreas administrativas como a las operaciones portuarias. En términos generales, el consumo de agua potable en instalaciones portuarias está relacionado principalmente con servicios sanitarios, edificios administrativos, áreas de mantenimiento y actividades de limpieza.

Para efectos de dimensionamiento preliminar, puede considerarse una dotación promedio de entre 100 y 150 litros por persona por día para instalaciones administrativas, conforme a los criterios de diseño utilizados en sistemas urbanos de abastecimiento de agua. Sin embargo, en áreas operativas portuarias es común considerar consumos adicionales asociados a limpieza de patios, control de polvo y mantenimiento de equipos.

El sistema debe diseñarse con capacidad suficiente para atender la demanda máxima diaria del puerto, considerando además un volumen de almacenamiento que permita garantizar la continuidad del suministro en caso de interrupciones temporales del abastecimiento externo. Este almacenamiento suele dimensionarse para cubrir entre 24 y 48 horas de consumo del sistema.

El análisis hidráulico de la red debe considerar velocidades de flujo adecuadas en las tuberías, generalmente entre 0.6 y 2.5 m/s, con el fin de evitar problemas de sedimentación o pérdidas de carga excesivas. Los diámetros de las tuberías principales deben seleccionarse de manera que permitan mantener presiones operativas adecuadas en toda la red, incluso en las terminales ubicadas en los puntos más alejados del sistema.

3.4.3 Dimensionamiento Preliminar de la Red Contra Incendio

El dimensionamiento del sistema contra incendio debe cumplir con los criterios establecidos en normas internacionales como NFPA 24 y NFPA 13. Estas normas establecen que el sistema debe ser capaz de suministrar caudales suficientes para la operación simultánea de hidrantes y sistemas de rociadores automáticos en áreas de riesgo.

En instalaciones industriales y portuarias, los caudales requeridos para sistemas contra incendio suelen situarse entre 2,000 y 5,000 galones por minuto, dependiendo del tipo de riesgo asociado a las instalaciones protegidas. En el caso de terminales portuarias con almacenamiento de contenedores y carga general, el sistema debe dimensionarse para cubrir escenarios de incendio en áreas abiertas de gran superficie.

El tanque de almacenamiento contra incendio debe tener capacidad suficiente para sostener el caudal de diseño durante un periodo mínimo de dos horas, conforme a las recomendaciones de las normas NFPA. La red de tuberías debe dimensionarse para garantizar presiones adecuadas en los hidrantes más alejados del sistema, considerando pérdidas de carga y condiciones de operación simultánea.

3.4.4 Dimensionamiento Preliminar del Drenaje Pluvial

El diseño del sistema de drenaje pluvial debe basarse en un análisis hidrológico que considere las intensidades de lluvia características de la región de Manzanillo. Estas intensidades deben obtenerse a partir de curvas de intensidad-duración-frecuencia desarrolladas para estaciones meteorológicas cercanas.

En áreas portuarias con grandes superficies impermeables, el cálculo de caudales de escurrimiento puede realizarse mediante el método racional, utilizando coeficientes de escurrimiento elevados que reflejen la baja infiltración del suelo en patios pavimentados. Los colectores pluviales deben dimensionarse para transportar los caudales generados por eventos de lluvia con periodos de retorno adecuados para infraestructura crítica.

El diseño del sistema debe considerar la posibilidad de mareas elevadas y niveles variables de la laguna, lo cual puede influir en la capacidad de descarga del sistema. En ciertos casos puede ser necesario incorporar estaciones de bombeo pluvial o estructuras de compuertas que permitan controlar el flujo hacia los cuerpos de agua receptores.

3.4.5 Dimensionamiento Preliminar del Drenaje Sanitario

El dimensionamiento del sistema sanitario debe basarse en la estimación de las aguas residuales generadas por las instalaciones administrativas, las áreas de servicio y las terminales portuarias. En términos generales, el caudal de aguas residuales puede estimarse como un porcentaje del consumo de agua potable, considerando factores de retorno típicos entre 80 y 90 por ciento.

El diseño hidráulico del sistema debe garantizar pendientes adecuadas en las tuberías para asegurar la autolimpieza de los conductos, evitando acumulación de sólidos. Las velocidades mínimas de flujo deben mantenerse por encima de 0.6 m/s para evitar sedimentación.

Dependiendo de la topografía del sitio, puede ser necesario incorporar estaciones de bombeo sanitario que permitan transportar el flujo hacia plantas de tratamiento o puntos de descarga autorizados.

3.4.6 Dimensionamiento Preliminar de la Red de Telecomunicaciones

El sistema de telecomunicaciones debe dimensionarse considerando las necesidades de conectividad del puerto en términos de transmisión de datos, control operativo, videovigilancia y comunicaciones institucionales. La red troncal de fibra óptica debe diseñarse con capacidad suficiente para soportar múltiples servicios simultáneos, incluyendo redes de datos, sistemas de seguridad, control de accesos y monitoreo de operaciones.

La infraestructura de ductería debe prever espacio adicional para cables futuros, lo cual permitirá la expansión del sistema sin necesidad de realizar excavaciones adicionales.

3.5 Criterios de Localización de Nodos de Infraestructura del Puerto

La localización de los nodos principales de infraestructura constituye un aspecto crítico en la planificación de redes dentro de desarrollos portuarios. Estos nodos representan puntos estratégicos desde los cuales se distribuyen los servicios hacia las distintas áreas del recinto portuario.

Desde el punto de vista de la ingeniería, la selección de la ubicación de estos nodos debe basarse en criterios de accesibilidad, eficiencia hidráulica o eléctrica, seguridad operativa y compatibilidad con el crecimiento futuro del puerto.

3.5.1 Localización de la Subestación Eléctrica Principal

La subestación principal debe ubicarse en una zona del puerto que permita una conexión eficiente con la red eléctrica regional y que al mismo tiempo facilite la distribución de energía hacia las terminales. En términos generales, esta instalación debe localizarse cerca de los accesos terrestres del puerto, donde es posible realizar la interconexión con líneas de transmisión o subtransmisión existentes.

Asimismo, la ubicación de la subestación debe considerar la disponibilidad de espacio suficiente para ampliaciones futuras, así como la accesibilidad para vehículos de mantenimiento y la separación adecuada respecto a áreas operativas con alto tránsito de carga.

3.5.2 Localización de Nodos Hidráulicos

Los nodos principales del sistema hidráulico, incluyendo tanques de almacenamiento y estaciones de bombeo, deben ubicarse en puntos que permitan una distribución equilibrada del agua a lo largo del recinto portuario. En proyectos de gran extensión, suele ser conveniente ubicar estos nodos cerca del centro geométrico del desarrollo, lo cual reduce las pérdidas de carga en la red y facilita el control hidráulico del sistema.

La ubicación de estos elementos también debe considerar condiciones topográficas que permitan optimizar la presión del sistema y minimizar la necesidad de bombeo adicional.

3.5.3 Localización de Estaciones de Bombeo

Las estaciones de bombeo asociadas a sistemas pluviales o sanitarios deben ubicarse en puntos bajos del terreno donde converjan los flujos naturales de escurrimiento. En el caso del proyecto de ampliación del Puerto de Manzanillo, la proximidad con la Laguna de Cuyutlán y la baja elevación del terreno hacen particularmente importante el análisis de las cotas hidráulicas para definir la ubicación adecuada de estos equipos.

3.5.4 Localización del Centro de Control Portuario

El centro de control portuario constituye el nodo principal para la gestión operativa del recinto. Este centro debe ubicarse en una zona segura del puerto, preferentemente cercana a las áreas administrativas y con acceso directo a las redes de telecomunicaciones y energía eléctrica.

Desde este punto se coordinan funciones críticas como la videovigilancia, el control de accesos, la gestión de tráfico interno y la supervisión de las operaciones portuarias.

3.5.5 Localización de Corredores de Utilidades

Los corredores de utilidades deben localizarse preferentemente a lo largo de las vialidades principales del puerto, donde es posible concentrar múltiples redes de infraestructura sin interferir con las áreas operativas de las terminales. Esta configuración facilita la instalación y mantenimiento de las redes y permite ampliar los sistemas en etapas futuras.

4.0 SISTEMA DE SUMINISTRO DE AGUA POTABLE.

4.1 Introducción.

El desarrollo del sistema de suministro de agua potable para el proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán constituye un componente estratégico para garantizar la operación continua, segura y sostenible de las instalaciones portuarias. Dada la ubicación del proyecto en un entorno costero-lagunar, caracterizado por condiciones geotécnicas complejas y posible influencia salina en acuíferos, el diseño del sistema debe responder a criterios de confiabilidad, redundancia, calidad sanitaria y adaptabilidad a condiciones variables del recurso hídrico.

El presente capítulo define las características técnicas que debe cumplir el sistema de abastecimiento, integrado por fuente de extracción subterránea, planta potabilizadora, almacenamiento, rebombeo y red de distribución, así como los lineamientos normativos aplicables en el contexto mexicano.

4.2 Configuración General del Sistema.

La configuración general del sistema de suministro de agua potable para el desarrollo portuario de Cuyutlán debe entenderse como una infraestructura hidráulica integral, concebida para captar, acondicionar, potabilizar, almacenar, bombear y distribuir agua en condiciones de continuidad, seguridad sanitaria y confiabilidad operativa. En un proyecto portuario de esta escala, el sistema no puede plantearse como una instalación aislada o de respuesta inmediata a una demanda puntual, sino como una red estructurada que debe operar de manera permanente, con capacidad de crecer por etapas conforme avance la ocupación del puerto, aumente la densidad de servicios y se consoliden nuevas áreas operativas, administrativas y logísticas.

Desde el punto de vista funcional, el sistema debe estar compuesto por cinco subsistemas principales, ver Figura 4.1. El primero corresponde a la fuente de abastecimiento, constituida por uno o más pozos profundos de extracción de agua subterránea. El segundo subsistema corresponde a la conducción de agua cruda, es decir, el conjunto de tuberías, válvulas, instrumentación y elementos de control encargados de transportar el agua desde el pozo hasta las instalaciones de tratamiento. El tercer subsistema es la planta potabilizadora, concebida como el núcleo del sistema, donde el agua extraída recibe los tratamientos requeridos para cumplir con los parámetros de calidad sanitaria aplicables para uso y consumo humano. El cuarto subsistema corresponde al almacenamiento y rebombeo, cuya función es regular caudales, mantener reservas operativas y asegurar una presión adecuada en la red. El quinto subsistema es la red de distribución interna del puerto, a través de la cual el agua potable se conduce hasta los diferentes puntos de consumo.

Figura 4.1 Sistema Conceptual de Suministro de Agua Potable.

Fuente: Elaboración propia, RHG Ingeniería, 2026.

La decisión de estructurar el sistema de esta manera obedece a la necesidad de asegurar una operación estable en un entorno con múltiples fuentes de incertidumbre. La Laguna de Cuyutlán presenta condiciones particulares que influyen directamente en el diseño del sistema hidráulico, entre ellas la cercanía al mar, la posible influencia de intrusión salina, la agresividad ambiental sobre equipos y materiales, la alta humedad, la complejidad de los suelos y la previsión de crecimiento progresivo del desarrollo portuario. En consecuencia, la configuración general debe responder a criterios de robustez, modularidad y redundancia, evitando soluciones únicas o rígidas que limiten la continuidad del servicio o dificulten la expansión futura.

En términos conceptuales, la fuente primaria de abastecimiento debe considerarse subterránea, mediante aprovechamiento controlado del acuífero local, siempre condicionado a la disponibilidad real del recurso y a los permisos aplicables. Esto implica que el sistema debe diseñarse no solo a partir de una necesidad de consumo, sino de un equilibrio entre demanda proyectada, capacidad de extracción sostenible, calidad del agua cruda y viabilidad regulatoria. En este sentido, la configuración general no debe descansar sobre un solo pozo como fuente exclusiva, ya que esa condición introduce vulnerabilidad operativa. La práctica técnicamente recomendable para instalaciones estratégicas es prever al menos una configuración con redundancia parcial, ya sea mediante dos pozos de producción, un pozo principal y uno de respaldo, o una solución escalable donde la segunda fuente pueda incorporarse en la siguiente etapa del desarrollo.

Una vez extraída, el agua no debe pasar directamente a la red de consumo ni a la planta sin regulación previa. Por ello, dentro de la configuración general resulta necesario incorporar una línea de agua cruda y un sistema de amortiguamiento hidráulico, normalmente mediante un tanque o cisterna de agua cruda. Este componente cumple varias funciones esenciales. En primer lugar, desacopla la operación del pozo respecto de la planta potabilizadora, lo cual permite absorber variaciones de caudal y estabilizar el régimen de operación del tratamiento. En segundo lugar, facilita maniobras de mantenimiento, paro y arranque sin comprometer de inmediato la disponibilidad del recurso. En tercer lugar, actúa como punto de control donde pueden realizarse mediciones, toma de muestras y evaluaciones de calidad antes del proceso de potabilización.

La planta potabilizadora debe configurarse como una instalación modular. Este criterio es especialmente importante en una infraestructura portuaria, donde la demanda no es estática y la expansión funcional puede modificar significativamente los requerimientos de agua potable con el paso del tiempo. La modulación significa que la planta no debe proyectarse como un bloque único de capacidad fija, sino como un conjunto de unidades o trenes de tratamiento que puedan operar de manera independiente o conjunta. Este enfoque permite mantener continuidad durante mantenimientos, facilita la ampliación por etapas y reduce la vulnerabilidad del sistema frente a fallas parciales.

En términos de operación, una configuración tipo dos módulos al cincuenta por ciento o tres módulos al treinta y tres por ciento representa una solución técnicamente adecuada. Bajo este esquema, el sistema puede seguir suministrando agua aun cuando uno de los módulos salga temporalmente de servicio. Esto resulta especialmente valioso en un puerto, donde la interrupción del suministro puede afectar oficinas, sanitarios, edificios operativos, puestos de inspección, talleres, comedores, sistemas de atención al personal y otras instalaciones esenciales.

La configuración del proceso de potabilización debe mantenerse flexible en la etapa conceptual. En un entorno costero, no es prudente asumir desde el inicio que el agua subterránea tendrá siempre características favorables. Por ello, el sistema debe admitir dos rutas de diseño. La primera corresponde a un tratamiento convencional reforzado, aplicable cuando el agua cruda presenta baja turbidez, contenidos controlables de hierro, manganeso o dureza, y ausencia de salinidad significativa. La segunda corresponde a un tratamiento avanzado compatible con remoción de sales, particularmente mediante membranas, si los estudios posteriores demuestran presencia relevante de conductividad elevada o riesgo de intrusión marina. La importancia de esta dualidad radica en que evita sobredimensionar innecesariamente el sistema, pero al mismo tiempo impide que la infraestructura quede limitada frente a una calidad de agua más exigente.

Después del tratamiento, la configuración general debe incorporar almacenamiento de agua potable. Este componente no es simplemente un tanque de reserva, sino un elemento de regulación estratégica dentro del sistema. Su presencia permite absorber variaciones horarias de demanda, asegurar continuidad durante eventos de mantenimiento o fallas momentáneas y

disponer de un volumen de seguridad frente a contingencias. En desarrollos portuarios, donde la continuidad del servicio es prioritaria, la reserva operativa debe plantearse con criterio conservador, buscando al menos cubrir un periodo suficiente para enfrentar interrupciones transitorias sin comprometer la operación esencial del puerto.

El almacenamiento de agua potable debe complementarse con una estación de rebombeo. La función de esta estación es mantener la presión de servicio necesaria para conducir el agua desde el punto de producción hasta los distintos sectores del desarrollo portuario. En una configuración técnicamente sólida, las bombas no deben plantearse como unidades únicas, sino bajo esquemas redundantes del tipo duty-standby o equivalente, donde exista al menos una bomba en operación y otra en respaldo. Este arreglo mejora la confiabilidad del sistema y permite mantenimiento sin detener el servicio. Adicionalmente, en proyectos de gran extensión, el rebombeo puede requerir sectorización hidráulica o incluso estaciones secundarias conforme se expanda el polígono portuario.

La red de distribución constituye el último subsistema de la configuración general, pero su papel es tan relevante como el de la fuente o la planta. La red debe diseñarse como una infraestructura primaria de servicio estratégico y no únicamente como una instalación complementaria. En términos conceptuales, es recomendable que la distribución se estructure mediante una red principal anillada o mallada en las zonas críticas, en lugar de una red estrictamente ramificada. Una red mallada ofrece ventajas importantes: mejora la continuidad del suministro, facilita el aislamiento de tramos por mantenimiento, permite un mejor balance de presiones y reduce el riesgo de dejar sectores completos fuera de servicio ante fallas localizadas.

Además, la configuración general debe prever desde su concepción la sectorización del sistema. Esto significa dividir hidráulicamente la red en zonas funcionales o de consumo, de modo que puedan controlarse caudales, detectar pérdidas, administrar presiones y priorizar servicios en caso de contingencia. En un entorno portuario, esta sectorización puede responder tanto a criterios hidráulicos como operativos, separando por ejemplo zonas administrativas, zonas de servicios, edificios técnicos, áreas de mantenimiento y otras unidades funcionales.

Otro aspecto clave de la configuración general es la diferenciación entre agua potable y agua para usos no potables. Aunque el presente sistema se refiere al suministro de agua potable, desde la ingeniería básica es recomendable reconocer que no todos los consumos del puerto requieren calidad de potabilización. Esto abre la posibilidad de que, en etapas posteriores, el sistema general del puerto se complemente con circuitos diferenciados para servicios, riego, ciertos lavados, reserva contra incendio o usos industriales, dejando que la red potabilizada atienda únicamente los puntos que realmente requieren calidad sanitaria. Esta separación mejora la eficiencia del sistema, reduce costos de tratamiento y permite una gestión más racional del recurso.

La configuración general también debe contemplar un sistema de instrumentación, control y monitoreo. En la actualidad, un sistema hidráulico de este tipo no debería concebirse sin elementos básicos de automatización. Esto incluye medición de caudales en extracción y distribución, monitoreo de niveles en tanques, control de presiones, parámetros de calidad del agua y alarmas operativas. La incorporación de supervisión remota o telemetría permite mejorar la capacidad de respuesta ante fallas, optimizar la operación del sistema y reducir el riesgo de interrupciones prolongadas. En un puerto moderno, esta capacidad de monitoreo no debe verse como un complemento, sino como parte constitutiva del sistema.

Desde la perspectiva constructiva, la configuración general también debe responder a la realidad física del sitio. Los equipos, tanques, conducciones y edificios de la planta deberán localizarse en áreas seguras, accesibles y técnicamente aptas, considerando la estabilidad del terreno, el riesgo de inundación, la facilidad de acceso para mantenimiento y la protección frente al ambiente marino. La configuración espacial debe asegurar que la planta y los tanques cuenten con vialidades de servicio, áreas de maniobra, espacio para sustitución de equipos, posibilidad de ampliación y protección perimetral adecuada. En la Laguna de Cuyutlán, estos criterios son particularmente relevantes debido a la sensibilidad del entorno y a la necesidad de construir sobre suelos potencialmente blandos o mejorados.

En el caso específico del pozo, su integración dentro de la configuración general exige considerar no solo la perforación, sino también la protección sanitaria, la instrumentación, la caseta de control, las líneas de descarga y la posibilidad de conexión con la planta sin introducir vulnerabilidades. La localización del pozo debe alejarse de posibles fuentes de contaminación, prever accesibilidad permanente y permitir su operación segura sin interferir con el resto de los sistemas del puerto. Además, si el sistema contempla más de un pozo, la configuración general debe distribuirlos de manera que se minimicen interferencias hidráulicas entre sí y se preserve la sostenibilidad de la extracción.

En términos de crecimiento, la configuración general debe ser escalable. Esto significa que la primera etapa del sistema no debe sobredimensionarse hasta volverse ineficiente, pero tampoco debe quedar tan ajustada que impida la expansión futura. La solución recomendada es un esquema por etapas, donde la infraestructura troncal esencial quede definida desde el inicio y ciertos componentes, como módulos de tratamiento, bombas adicionales, tanques complementarios o ampliaciones de red, puedan incorporarse conforme avance el desarrollo del puerto. Esta lógica permite equilibrar inversión inicial y capacidad futura, manteniendo coherencia técnica y operativa.

En síntesis, la configuración general del sistema de suministro de agua potable para el desarrollo portuario de Cuyutlán debe concebirse como un sistema integrado, redundante, modular, escalable y controlado, compuesto por fuente subterránea, conducción de agua cruda, potabilización, almacenamiento, rebombeo y distribución. Su diseño debe responder no solo a criterios hidráulicos y sanitarios, sino también a la lógica operativa de una instalación portuaria

estratégica, a las restricciones del entorno lagunar y a la necesidad de asegurar continuidad y confiabilidad a largo plazo. Bajo esta visión, el sistema deja de ser un simple conjunto de tuberías y equipos, y se convierte en una infraestructura crítica de soporte al funcionamiento del puerto ampliado.

4.3 Características Técnicas del Sistema de Abastecimiento

El sistema de abastecimiento de agua potable para el desarrollo portuario de Cuyutlán debe definirse a partir de criterios técnicos que garanticen su confiabilidad, eficiencia hidráulica, calidad sanitaria y adaptabilidad a las condiciones particulares del sitio. A diferencia de sistemas urbanos convencionales, en los que la variabilidad de la demanda y las condiciones del entorno suelen ser más estables, un sistema portuario debe responder a dinámicas operativas cambiantes, demandas concentradas en ciertos puntos y la necesidad de continuidad absoluta del servicio. En este contexto, las características técnicas del sistema no deben entenderse como parámetros aislados, sino como un conjunto de atributos interrelacionados que definen su desempeño global.

Desde el punto de vista estructural, el sistema debe diseñarse como una infraestructura modular, escalable y redundante. La modulación implica que los principales componentes, particularmente la planta potabilizadora y los sistemas de bombeo, se encuentren divididos en unidades independientes que puedan operar de manera individual o conjunta. Esta característica permite ajustar la capacidad del sistema a las diferentes etapas de desarrollo del puerto, evitando sobredimensionamientos iniciales y facilitando ampliaciones futuras. Al mismo tiempo, la redundancia operativa debe incorporarse como criterio fundamental, de manera que la falla o mantenimiento de un componente no implique la interrupción total del servicio.

En términos de capacidad, el sistema debe dimensionarse con base en una demanda proyectada por etapas. Como criterio conceptual, una capacidad inicial de producción del orden de 15 a 30 litros por segundo resulta adecuada para una primera etapa, equivalente aproximadamente a entre 1,296 y 2,592 metros cúbicos por día. Conforme el puerto incremente su actividad, el sistema debe escalar hacia rangos de 30 a 50 litros por segundo en una etapa intermedia, y eventualmente hacia 50 a 80 litros por segundo en una fase de consolidación. Esta evolución confirma la necesidad de un diseño modular desde el origen.

La eficiencia hidráulica constituye un aspecto clave en la definición técnica del sistema. Las pérdidas de carga deben mantenerse dentro de rangos controlados mediante el diseño adecuado de diámetros, selección de materiales y disposición de equipos. La presión de operación en la red debe garantizar el suministro en todos los puntos de consumo, manteniéndose típicamente en rangos conceptuales del orden de 2.5 a 5.0 kg/cm². Para lograr esto, el sistema debe incorporar almacenamiento estratégico y estaciones de bombeo adecuadamente dimensionadas.

El sistema debe incluir almacenamiento tanto de agua cruda como de agua potable. El tanque de agua cruda permite estabilizar la operación del pozo y asegurar una alimentación

continua a la planta potabilizadora. A nivel conceptual, este tanque puede dimensionarse entre 4 y 8 horas de producción, lo que equivale aproximadamente a 300 a 900 metros cúbicos en una etapa inicial. Por su parte, el almacenamiento de agua potable debe cubrir al menos un día de consumo, recomendándose rangos preliminares entre 1,500 y 5,000 metros cúbicos en etapas iniciales, incrementándose conforme crece la demanda del puerto.

En lo que respecta al pozo de abastecimiento, sus características técnicas deben asegurar una extracción eficiente y sostenible. Un pozo típico en este tipo de desarrollo puede diseñarse con capacidades del orden de 10 a 20 litros por segundo, profundidades entre 60 y 150 metros y diámetros aproximados de 12 a 18 pulgadas. Es recomendable considerar al menos dos pozos en configuración operativa o de respaldo, con el fin de reducir riesgos y mejorar la confiabilidad del sistema. El diseño debe incluir ademe sanitario, sección filtrante adecuada, sellado superior y sistemas de monitoreo de caudal y niveles.

La planta potabilizadora debe configurarse como un sistema modular. Para una primera etapa, puede plantearse una configuración de dos módulos de 15 litros por segundo o tres módulos de 10 litros por segundo. Este arreglo permite mantener la operación aun cuando uno de los módulos se encuentre fuera de servicio. El proceso de tratamiento debe incluir pretratamiento, filtración y desinfección, y debe mantener flexibilidad para incorporar tecnologías avanzadas como ósmosis inversa en caso de detectarse salinidad. En este último caso, debe considerarse una recuperación conceptual del orden de 70% a 85%, lo que impacta directamente en el volumen de agua cruda requerido.

El sistema de bombeo debe diseñarse con redundancia. A nivel conceptual, se recomienda una configuración de dos a tres bombas, con esquemas tipo duty-standby. Para una etapa inicial de 20 a 30 litros por segundo, las bombas pueden dimensionarse entre 10 y 20 litros por segundo por unidad, con cargas dinámicas estimadas del orden de 20 a 40 metros de columna de agua, dependiendo de la red.

La red de distribución debe estructurarse como una red troncal primaria con configuración mallada en zonas críticas. A nivel conceptual, los diámetros principales pueden ubicarse entre 8 y 14 pulgadas, mientras que las líneas secundarias pueden variar entre 2 y 8 pulgadas, dependiendo del consumo local. La sectorización de la red es fundamental para mejorar el control hidráulico, facilitar mantenimiento y detectar fugas.

En términos de materiales, todos los componentes del sistema deben ser resistentes a condiciones de ambiente marino, incluyendo tuberías de polietileno de alta densidad, PVC hidráulico o acero protegido, así como estructuras con recubrimientos anticorrosivos. Este criterio es esencial en la Laguna de Cuyutlán debido a la agresividad ambiental.

El sistema debe incorporar instrumentación y control. Es indispensable medir caudales de extracción, producción y distribución, niveles en tanques, presiones en la red y parámetros de

calidad como turbidez, pH, conductividad y cloro residual. A nivel conceptual, el sistema debe contemplar automatización básica con capacidad de monitoreo remoto.

Desde la perspectiva de implantación, una planta modular inicial de 20 a 30 litros por segundo puede requerir entre 2,000 y 5,000 metros cuadrados de superficie, considerando áreas de operación, mantenimiento y expansión futura. Este aspecto debe integrarse desde la planeación para evitar limitaciones en etapas posteriores. A continuación, en la Tabla 4.1, se integran las capacidades aproximadas.

Tabla 4.1 Capacidades Aproximadas del Sistema de Agua Potable.

COMPONENTE	ETAPAS		
	PRIMERA	INTERMEDIA	CONSOLIDADA
Producción	15–30 l/s	30–50 l/s	50–80 l/s
Producción diaria	1,296–2,592 m^3/día	2,592–4,320 m^3/día	4,320–6,912 m^3/día
Continuidad de operación	24/7	24/7	24/7
Redundancia	Alta	Alta	Alta
Pozos	1 + 1 reserva	2	3
Gasto por pozo	10–20 l/s	15–20 l/s	15–25 l/s
Tanque agua cruda	300–900 m^3	600–1,200 m^3	1,000–2,000 m^3
Almacenamiento potable	1,500–5,000 m^3	3,000–8,000 m^3	5,000–12,000 m^3
Presión en red	2.5 – 5.0 kg/cm^2	2.5 – 5.0 kg/cm^2	2.5 – 5.0 kg/cm^2
Bombas	2–3	3	3–4
Capacidad de bombas	10–20 l/s	15–25 l/s	20–30 l/s
Red troncal	8 – 12 in	10 – 14 in	12 – 16 in
Automatización	Básica con monitoreo	Avanzada	Avanzada
Tratamiento	Convencional	Convencional/ avanzado	Convencional/ avanzado

Nota: En conjunto, estas características técnicas, complementadas con capacidades aproximadas, permiten definir un sistema robusto, modular, redundante y escalable, adecuado para las condiciones del desarrollo portuario de Cuyutlán.
Fuente: Elaboración propia, RHG Ingeniería, 2026.

Estas capacidades aproximadas permiten brindar una idea de una escala más útil para planeación. Sin embargo, es importante insistir en que los valores finales deberán ajustarse con

base en el estudio de demanda, el estudio geohidrológico, la calidad del agua cruda, la modelación hidráulica y la estrategia de crecimiento del puerto. En otras palabras, estos rangos deben leerse como una base de ingeniería conceptual que orienta la toma de decisiones y no como un diseño definitivo.

La confiabilidad del sistema se fortalece mediante la integración de instrumentación y control. El sistema debe contar con medición continua de caudales de extracción, producción y distribución, niveles en tanques, presiones en la red y parámetros de calidad como turbidez, pH, conductividad y cloro residual. A nivel conceptual, debe considerarse la implementación de un sistema de control automatizado con capacidad de monitoreo remoto, lo que permite operar el sistema de manera eficiente y detectar desviaciones de forma oportuna.

En síntesis, las características técnicas del sistema con capacidades aproximadas permiten visualizar con mayor claridad la escala de infraestructura requerida para el puerto de Cuyutlán. Asimismo, se confirma que el sistema debe concebirse como una instalación robusta, modular, redundante y escalable, capaz de suministrar agua potable en forma continua, de adaptarse al crecimiento del puerto y de responder a las condiciones particulares del entorno costero-lagunar. Bajo este enfoque, la definición conceptual del sistema gana solidez técnica y proporciona una base más clara para la ingeniería de detalle y la planeación integral del proyecto.

4.3.1 Características del Pozo de Abastecimiento

El pozo de abastecimiento constituye el elemento primario del sistema de suministro de agua potable y, por tanto, su definición técnica debe abordarse con un alto nivel de rigor, ya que de él dependen la disponibilidad, calidad y sostenibilidad del recurso hídrico. En el contexto del desarrollo portuario de Cuyutlán, el diseño del pozo no puede limitarse a un criterio hidráulico simple de extracción, sino que debe integrar consideraciones geohidrológicas, constructivas, operativas, sanitarias y regulatorias, particularmente debido a la cercanía con el litoral y el riesgo potencial de intrusión salina.

Desde el punto de vista geohidrológico, el diseño del pozo debe basarse en un estudio detallado del acuífero, que incluya la caracterización estratigráfica del subsuelo, la identificación de horizontes permeables, la determinación de niveles estáticos y dinámicos, así como la evaluación de la transmisividad y almacenamiento del acuífero. Este estudio debe complementarse con pruebas de bombeo escalonadas y de larga duración, que permitan establecer el gasto sostenible del pozo, evitando sobreexplotación o abatimientos excesivos que puedan inducir la migración de agua salina hacia el punto de extracción.

En términos de capacidad, el pozo debe diseñarse para operar dentro de un rango conceptual de entre 10 y 20 litros por segundo en una etapa inicial, con posibilidad de incrementarse hasta valores de 20 a 25 litros por segundo en etapas avanzadas, dependiendo de la respuesta del acuífero. Este rango permite integrar el pozo dentro de un sistema modular,

donde múltiples fuentes pueden operar de manera conjunta o alternada, reduciendo la dependencia de una sola captación y mejorando la confiabilidad del sistema.

La profundidad del pozo estará determinada por la ubicación del acuífero aprovechable y la calidad del agua, pero a nivel conceptual puede estimarse dentro de un rango de 60 a 150 metros. Este intervalo es consistente con acuíferos costeros de media profundidad, aunque la definición final deberá basarse en la exploración geofísica y en los resultados de la perforación piloto. El diámetro del pozo, por su parte, debe ser suficiente para alojar el ademe, la sección filtrante y el equipo de bombeo, ubicándose típicamente entre 12 y 18 pulgadas en esta etapa conceptual.

La configuración constructiva del pozo debe incluir un ademe sanitario en la sección superior, cuya función es aislar el pozo de infiltraciones superficiales y proteger la calidad del agua. En la zona productiva, el pozo debe contar con una sección filtrante diseñada en función de la granulometría del material geológico, permitiendo la entrada de agua y evitando la migración de finos hacia el interior del pozo. Cuando las condiciones lo requieran, se debe incorporar un empaque de grava entre la pared del pozo y el ademe, lo que mejora la eficiencia hidráulica y prolonga la vida útil de la captación.

El sellado sanitario en la parte superior del pozo es un elemento crítico, particularmente en entornos donde existe riesgo de contaminación superficial. Este sellado debe impedir la entrada de aguas pluviales, contaminantes o material superficial, garantizando que el agua extraída provenga exclusivamente del acuífero protegido. Adicionalmente, el cabezal del pozo debe diseñarse como una estructura segura, accesible y protegida, que permita la operación del equipo de bombeo y el monitoreo de parámetros sin comprometer la integridad del sistema.

El equipo de bombeo debe seleccionarse en función del gasto de diseño, la profundidad del pozo y la carga dinámica total. En un pozo de estas características, es común el uso de bombas sumergibles multietapa, diseñadas para operar de manera continua y eficiente. La potencia del equipo dependerá de la profundidad de instalación y del caudal requerido, pero debe considerarse siempre la incorporación de sistemas de protección eléctrica, arranque suave y control de operación.

Desde el punto de vista operativo, el pozo debe contar con instrumentación que permita monitorear su desempeño en tiempo real. Esto incluye medidores de caudal, sensores de nivel dinámico, válvulas de control, puertos de muestreo y sistemas de medición de energía. La información generada por estos dispositivos es fundamental para evaluar el comportamiento del acuífero, detectar anomalías y optimizar la operación del sistema.

En términos de calidad del agua, es indispensable realizar análisis fisicoquímicos y bacteriológicos completos, tanto durante la fase de exploración como en la operación regular del pozo. Estos análisis permiten definir el tipo de tratamiento requerido en la planta potabilizadora y

detectar posibles cambios en la calidad del agua a lo largo del tiempo. En un entorno costero, la conductividad eléctrica y el contenido de cloruros son parámetros especialmente relevantes para identificar la presencia de intrusión salina.

La ubicación del pozo dentro del proyecto debe seleccionarse cuidadosamente, considerando la distancia a posibles fuentes de contaminación, la accesibilidad para operación y mantenimiento, y la interacción con otros componentes del sistema. En proyectos portuarios, es recomendable ubicar los pozos en zonas protegidas, fuera de áreas de tráfico pesado o riesgo industrial, pero con conexión eficiente hacia la planta potabilizadora.

Desde el punto de vista de redundancia, el sistema no debe depender de un solo pozo. La configuración recomendada consiste en al menos dos pozos, uno en operación y otro en reserva o en operación alternada, lo que permite realizar mantenimiento, enfrentar contingencias y gestionar de manera más eficiente el recurso hídrico. En etapas posteriores del desarrollo, puede considerarse la incorporación de un tercer pozo, dependiendo de la demanda y de la capacidad del acuífero. En la Tabla 4.2 se muestran las características técnicas aproximadas del pozo de abastecimiento a nivel conceptual.

Tabla 4.2 Características del Pozo del Sistema de Agua Potable.

PARÁMETRO	VALOR CONCEPTUAL
Tipo de pozo	Pozo profundo entubado
Gasto de diseño	10 – 20 l/s (hasta 25 l/s en etapas avanzadas)
Profundidad	60 – 150 m
Diámetro	12 – 18 pulgadas
Tipo de ademe	Acero o PVC sanitario
Sección filtrante	Según granulometría del acuífero
Empaque de grava	Según condiciones geológicas
Sellado sanitario	Obligatorio
Tipo de bomba	Sumergible multietapa
Instrumentación	Caudal, nivel, presión, muestreo
Pruebas requeridas	Escalonada y larga duración
Calidad del agua	Análisis fisicoquímico y bacteriológico
Número de pozos	1 operativo + 1 reserva (mínimo)

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Finalmente, el diseño del pozo debe alinearse con criterios de sostenibilidad y protección del acuífero. Esto implica operar dentro de los límites de extracción permitidos, evitar abatimientos excesivos, monitorear continuamente la calidad del agua y cumplir con los requisitos regulatorios aplicables. En este sentido, el pozo no solo debe concebirse como una obra de captación, sino como un elemento estratégico dentro del sistema hidráulico del puerto, cuya correcta operación garantizará la viabilidad del abastecimiento a largo plazo.

4.3.2 Características de la planta potabilizadora

La planta potabilizadora constituye el núcleo del sistema de abastecimiento de agua potable, ya que es el elemento encargado de transformar el agua cruda proveniente del acuífero en agua apta para uso y consumo humano, cumpliendo con los estándares de calidad establecidos en la normativa aplicable. En el contexto del desarrollo portuario de Cuyutlán, su diseño debe responder a condiciones particulares de operación continua, variabilidad potencial en la calidad del agua y requerimientos de alta confiabilidad, propios de una infraestructura crítica.

Desde el punto de vista conceptual, la planta debe diseñarse bajo un esquema modular, escalable y redundante. La modulación permite dividir la capacidad total de producción en unidades independientes, lo cual facilita la operación flexible del sistema, la ampliación por etapas y la continuidad del servicio durante actividades de mantenimiento. Una configuración técnica adecuada para la etapa inicial consiste en dos módulos de 15 litros por segundo o tres módulos de 10 litros por segundo, lo que permite cubrir una producción total de entre 20 y 30 litros por segundo con redundancia operativa. En etapas posteriores, pueden incorporarse módulos adicionales hasta alcanzar capacidades del orden de 50 a 80 litros por segundo.

El proceso de potabilización debe seleccionarse en función de la calidad del agua cruda. En condiciones favorables, donde el agua subterránea presenta baja turbidez y niveles controlables de hierro, manganeso o dureza, el sistema puede estructurarse mediante un tren convencional que incluya pretratamiento, filtración y desinfección. El pretratamiento puede consistir en procesos de aireación u oxidación para remover gases disueltos y facilitar la precipitación de metales. Posteriormente, la filtración puede realizarse mediante filtros multimedia a presión o por gravedad, diseñados para manejar cargas hidráulicas del orden de 5 a 15 $m^3/m^2 \cdot h$, dependiendo del tipo de medio filtrante.

La desinfección constituye la etapa final del tratamiento y es indispensable para garantizar la eliminación de microorganismos patógenos. A nivel conceptual, la cloración es el método más común, debiendo garantizarse un tiempo de contacto adecuado y un residual de cloro libre en la red conforme a la normativa vigente. Alternativamente, pueden considerarse sistemas complementarios como radiación ultravioleta, particularmente en esquemas donde se busque reducir subproductos de desinfección.

En un entorno como Cuyutlán, donde existe la posibilidad de intrusión salina o variaciones en la conductividad del agua subterránea, la planta debe diseñarse con flexibilidad para incorporar tratamientos avanzados. En estos casos, la ósmosis inversa se presenta como una tecnología viable para la remoción de sales disueltas. A nivel conceptual, un sistema de membranas puede diseñarse con recuperaciones del orden de 70% a 85%, lo que implica que una fracción del agua alimentada será rechazada como concentrado. Este aspecto debe considerarse desde la ingeniería básica, tanto en el dimensionamiento del sistema como en el manejo de descargas.

El dimensionamiento hidráulico de la planta debe asegurar que todos los procesos operen dentro de rangos adecuados de velocidad, presión y tiempo de contacto. Por ejemplo, los sistemas de filtración deben diseñarse para permitir retrolavados periódicos sin interrumpir la operación global, lo que refuerza la necesidad de contar con múltiples unidades en paralelo. Asimismo, los tanques de contacto para desinfección deben garantizar tiempos mínimos de retención que permitan la inactivación efectiva de patógenos.

La planta debe contar con sistemas auxiliares indispensables para su operación. Entre ellos se incluyen sistemas de dosificación química, equipos de almacenamiento y preparación de reactivos, sistemas de retrolavado de filtros, drenajes controlados y sistemas de ventilación. La dosificación de productos químicos, como coagulantes, oxidantes o desinfectantes, debe realizarse mediante equipos dosificadores precisos, con capacidad de ajuste en función de la calidad del agua.

Desde el punto de vista estructural, la planta debe diseñarse considerando el ambiente marino. Esto implica la selección de materiales resistentes a la corrosión, como acero inoxidable, recubrimientos especiales, plásticos de alta resistencia o concreto con protección adecuada. Los equipos deben instalarse en áreas accesibles, con suficiente espacio para operación, mantenimiento y reemplazo, y con una disposición que permita la ampliación futura sin afectar la operación existente.

La automatización de la planta constituye un elemento esencial de su diseño. El sistema debe contar con instrumentación para medir variables clave como caudal, presión, turbidez, pH, conductividad y cloro residual. Estos datos deben integrarse en un sistema de control que permita la operación automática bajo condiciones normales, así como la supervisión remota desde un centro de control. La automatización mejora la eficiencia operativa, reduce la dependencia de operación manual y permite una respuesta rápida ante desviaciones en la calidad del agua.

En términos de consumo energético, la planta debe diseñarse con criterios de eficiencia, seleccionando equipos que operen dentro de rangos óptimos y minimicen pérdidas. En el caso de sistemas con membranas, el consumo energético puede ser significativo, por lo que debe evaluarse cuidadosamente su incorporación y optimizarse mediante la selección adecuada de equipos y condiciones de operación.

La implantación de la planta dentro del proyecto debe considerar su accesibilidad, seguridad y relación con otros sistemas. A nivel conceptual, una planta con capacidad de 20 a 30 litros por segundo puede requerir entre 2,000 y 5,000 metros cuadrados de superficie, incluyendo áreas de tratamiento, almacenamiento, circulación, mantenimiento y expansión futura. Esta superficie debe incrementarse conforme se amplíe la capacidad del sistema. A continuación, en la Tabla 4.3 se presentan las características técnicas aproximadas de la planta potabilizadora.

Tabla 4.3 Características de la Planta Potabilizadora del Sistema de Agua Potable.

PARÁMETRO	VALOR CONCEPTUAL
Tipo de planta	Modular
Capacidad inicial	15 – 30 l/s
Capacidad futura	Hasta 80 l/s
Configuración	2x50% o 3x33%
Tipo de tratamiento	Convencional / avanzado
Pretratamiento	Aireación / oxidación
Filtración	Multimedia (5–15 $m^3/m^2 \cdot h$)
Desinfección	Cloración / UV
Tratamiento avanzado	Ósmosis inversa (si aplica)
Recuperación (membranas)	70% – 85%
Automatización	Sistema SCADA básico
Instrumentación	Caudal, presión, turbidez, pH, conductividad, cloro
Materiales	Resistentes a ambiente marino
Área estimada	2,000 – 5,000 m^2
Operación	Continua 24/7

Fuente: Elaboración propia, RHG Ingeniería, 2026.

En conjunto, estas características permiten definir una planta potabilizadora robusta, flexible y adaptable, capaz de responder a las condiciones del entorno lagunar y a las necesidades del desarrollo portuario. Su correcta definición desde la etapa conceptual garantiza no solo el cumplimiento de los estándares de calidad, sino también la continuidad operativa y la sostenibilidad del sistema de abastecimiento en el largo plazo.

4.3.3 Sistema de almacenamiento y distribución

El sistema de almacenamiento y distribución de agua potable constituye el componente encargado de garantizar la continuidad del servicio, la regulación hidráulica del sistema y la entrega del recurso en condiciones adecuadas de presión y calidad a todos los puntos de consumo del desarrollo portuario. En el contexto del proyecto de Cuyutlán, este subsistema adquiere una relevancia estratégica, ya que permite desacoplar la producción de agua respecto de la demanda, absorber variaciones operativas y asegurar el suministro ante contingencias o mantenimientos programados.

Desde el punto de vista funcional, el sistema se compone de tres elementos principales: almacenamiento de agua potable, estación de bombeo y red de distribución. Estos elementos deben operar de manera coordinada, de modo que el agua tratada en la planta potabilizadora pueda almacenarse temporalmente, impulsarse con la presión adecuada y distribuirse de forma eficiente a las distintas zonas del puerto.

El almacenamiento de agua potable representa el primer nivel de regulación del sistema. Su función principal es actuar como reserva operativa que permita mantener el suministro aun cuando la producción de la planta se vea interrumpida o limitada. En un desarrollo portuario, donde la continuidad del servicio es crítica, el volumen de almacenamiento debe dimensionarse con criterios conservadores. A nivel conceptual, se recomienda que el sistema cuente con una reserva mínima equivalente a un día de consumo promedio, pudiendo incrementarse hasta 1.5 o 2 días en función del nivel de seguridad requerido. Para una etapa inicial con demandas del orden de 1,500 a 2,500 metros cúbicos por día, esto implica capacidades de almacenamiento entre 1,500 y 5,000 metros cúbicos. En etapas de mayor desarrollo, este volumen puede incrementarse hasta rangos de 5,000 a 12,000 metros cúbicos.

Desde el punto de vista constructivo, los tanques de almacenamiento pueden ser de concreto reforzado, acero o materiales prefabricados, dependiendo de las condiciones del sitio y de los criterios de durabilidad. En el caso de Cuyutlán, es indispensable considerar la agresividad del ambiente marino, lo que implica el uso de recubrimientos anticorrosivos, concreto con diseño adecuado para ambientes agresivos o materiales poliméricos de alta resistencia. Asimismo, los tanques deben contar con sistemas de ventilación, drenaje, acceso para mantenimiento y dispositivos de medición de nivel.

La ubicación de los tanques dentro del sistema debe responder a criterios hidráulicos y operativos. Idealmente, deben situarse en puntos que permitan una distribución eficiente hacia la red, minimizando pérdidas de carga y facilitando la operación del sistema de bombeo. En proyectos de gran extensión, puede ser conveniente distribuir el almacenamiento en más de un punto, generando subzonas hidráulicas que mejoren el control del sistema.

La estación de bombeo constituye el elemento encargado de proporcionar la energía necesaria para impulsar el agua desde el almacenamiento hacia la red de distribución. Su diseño debe garantizar la presión requerida en todos los puntos de consumo, considerando las pérdidas por fricción, la topografía del terreno y las demandas simultáneas del sistema. A nivel conceptual, la presión de servicio en la red debe mantenerse en un rango aproximado de 2.5 a 5.0 kg/cm², suficiente para cubrir edificios, instalaciones operativas y servicios portuarios.

La configuración del sistema de bombeo debe incluir redundancia. Una disposición típica consiste en dos o tres bombas, donde al menos una opere como respaldo. En una etapa inicial con capacidades de 20 a 30 litros por segundo, las bombas pueden dimensionarse con capacidades unitarias de 10 a 20 litros por segundo. En etapas posteriores, estas capacidades pueden incrementarse hasta 20 o 30 litros por segundo por bomba, manteniendo siempre el criterio de respaldo. La carga dinámica total de diseño puede estimarse conceptualmente entre 20 y 40 metros de columna de agua, aunque este valor deberá ajustarse mediante modelación hidráulica detallada.

El sistema de bombeo debe incluir válvulas de control, válvulas de retención, sistemas de protección contra sobrepresión, dispositivos de arranque suave y sistemas de control automático. La incorporación de variadores de frecuencia puede mejorar la eficiencia energética y permitir un ajuste dinámico de la operación en función de la demanda.

La red de distribución representa el componente final del sistema y es responsable de conducir el agua potable hasta los distintos puntos de consumo dentro del puerto. A diferencia de redes simples, en este caso debe diseñarse como una infraestructura primaria, capaz de operar con confiabilidad, flexibilidad y control hidráulico. En términos conceptuales, se recomienda que la red adopte una configuración mallada en las zonas críticas, lo que permite mantener el suministro aun en caso de fallas o mantenimiento en ciertos tramos.

Los diámetros de la red deben definirse en función de los caudales requeridos, las longitudes de conducción y las pérdidas de carga admisibles. A nivel conceptual, la red troncal puede diseñarse con diámetros entre 8 y 14 pulgadas en etapas iniciales, incrementándose hasta 16 pulgadas en etapas de consolidación. Las líneas secundarias, que alimentan edificios y áreas específicas, pueden variar entre 2 y 8 pulgadas, dependiendo del consumo local.

La sectorización de la red constituye un elemento fundamental para la operación del sistema. Dividir la red en sectores hidráulicos permite controlar presiones, medir consumos, detectar fugas y realizar mantenimientos sin afectar la totalidad del sistema. En un entorno portuario, esta sectorización puede alinearse con la zonificación funcional del proyecto, separando áreas administrativas, operativas, de servicios y de infraestructura crítica.

En cuanto a materiales, la red debe construirse con tuberías resistentes a la corrosión y adecuadas para el ambiente marino. Materiales como el polietileno de alta densidad, el PVC

hidráulico o el acero con recubrimientos especiales son opciones viables, siempre que cumplan con los requisitos de presión y durabilidad. La selección final deberá considerar tanto criterios técnicos como económicos y de mantenimiento.

El sistema de distribución debe complementarse con instrumentación que permita monitorear su desempeño. Esto incluye medidores de caudal en puntos estratégicos, sensores de presión, válvulas de control y dispositivos para detección de fugas. La integración de estos elementos en un sistema de control centralizado permite mejorar la operación y reducir pérdidas de agua. A continuación, en la Tabla 4.4, se presentan las características técnicas aproximadas del sistema de almacenamiento y distribución.

Tabla 4.4 Características del Sistema de Distribución del Sistema de Agua Potable.

PARÁMETRO	VALOR CONCEPTUAL
Reserva de agua potable	1 a 2 días de consumo
Volumen inicial	1,500 – 5,000 m^3
Volumen futuro	5,000 – 12,000 m^3
Tipo de tanque	Concreto, acero o prefabricado
Presión en red	2.5 – 5.0 kg/cm^2
Número de bombas	2 – 3 (con respaldo)
Capacidad por bomba	10 – 30 l/s
Carga dinámica	20 – 40 m.c.a.
Configuración de red	Mallada
Diámetro red troncal	8 – 16 pulgadas
Diámetro red secundaria	2 – 8 pulgadas
Material de tubería	HDPE, PVC, acero protegido
Sectorización	Requerida
Instrumentación	Caudal, presión, control de fugas

Fuente: Elaboración propia, RHG Ingeniería, 2026.

El sistema de almacenamiento y distribución debe diseñarse como un subsistema robusto y flexible, capaz de garantizar la continuidad del suministro, adaptarse al crecimiento del puerto y operar de manera eficiente en un entorno complejo. Su correcta integración con la planta

potabilizadora y la fuente de abastecimiento es fundamental para asegurar el desempeño global del sistema hidráulico del desarrollo portuario de Cuyutlán

4.4 Aspecto Normativo.

El sistema de abastecimiento de agua potable para el desarrollo portuario de Cuyutlán debe diseñarse, construirse y operarse en estricto cumplimiento del marco normativo vigente en México, el cual regula tanto la calidad del agua para consumo humano como la explotación de fuentes subterráneas, la construcción de infraestructura hidráulica y la protección ambiental. El cumplimiento de este marco no solo es un requisito legal, sino también un elemento esencial para garantizar la seguridad sanitaria, la sostenibilidad del recurso hídrico y la viabilidad del proyecto a largo plazo.

Desde el punto de vista sanitario, la normativa principal que rige la calidad del agua potable es la NOM-127-SSA1-2021, la cual establece los límites permisibles de calidad del agua para uso y consumo humano. Esta norma define parámetros físicos, químicos y microbiológicos que deben cumplirse en el punto de entrega al usuario, incluyendo límites para turbidez, color, pH, sólidos disueltos totales, metales, compuestos orgánicos y microorganismos patógenos. En este sentido, la planta potabilizadora debe diseñarse de manera que garantice el cumplimiento continuo de estos parámetros, independientemente de las variaciones en la calidad del agua cruda.

Complementariamente, la NOM-230-SSA1-2002 establece los requisitos sanitarios para la construcción, operación y mantenimiento de los sistemas de abastecimiento de agua potable. Esta norma regula aspectos como la protección de las fuentes de abastecimiento, las condiciones de operación de los sistemas, la limpieza y desinfección de tanques, la frecuencia de muestreo y la vigilancia de la calidad del agua. En el caso del proyecto de Cuyutlán, esta norma es particularmente relevante para definir los procedimientos operativos del sistema, incluyendo el monitoreo de calidad y las actividades de mantenimiento preventivo.

En lo que respecta a la infraestructura hidráulica, la NOM-001-CONAGUA-2011 establece los criterios de hermeticidad que deben cumplir las redes de agua potable. Esta norma tiene como objetivo minimizar pérdidas de agua y evitar la contaminación del sistema durante su operación. Su cumplimiento implica la correcta selección de materiales, la ejecución adecuada de juntas y conexiones, así como la realización de pruebas de presión y hermeticidad durante la construcción.

El aprovechamiento de agua subterránea está regulado por la Ley de Aguas Nacionales y su reglamento, los cuales establecen que cualquier extracción de agua debe contar con un título de concesión otorgado por la Comisión Nacional del Agua (CONAGUA). Este título define el volumen máximo de extracción permitido, las condiciones de uso y las obligaciones del concesionario. En este contexto, el diseño del sistema debe alinearse con la disponibilidad del

acuífero y con los volúmenes autorizados, evitando sobreexplotación y garantizando la sostenibilidad del recurso.

Adicionalmente, la disponibilidad media anual del acuífero correspondiente debe ser considerada como un insumo fundamental para la planeación del sistema. Esta información, publicada por CONAGUA, permite determinar si el volumen requerido por el proyecto es viable desde el punto de vista hídrico y si existen restricciones que deban incorporarse en el diseño.

En materia de construcción de pozos, aunque las especificaciones técnicas pueden variar, existen lineamientos emitidos por CONAGUA que establecen criterios para la perforación, equipamiento, mantenimiento y cierre de pozos, con el objetivo de prevenir la contaminación de acuíferos. Estos lineamientos deben considerarse en el diseño del pozo de abastecimiento, particularmente en lo referente al sellado sanitario, la protección del cabezal y la integridad estructural de la obra.

Desde el punto de vista ambiental, el sistema debe cumplir con las disposiciones aplicables en materia de impacto ambiental, especialmente aquellas relacionadas con la protección de cuerpos de agua, manejo de descargas y preservación del entorno lagunar. En el caso de la planta potabilizadora, esto incluye el manejo adecuado de residuos, como el agua de retrolavado de filtros o el concentrado de sistemas de ósmosis inversa, los cuales deben ser dispuestos conforme a la normativa ambiental vigente.

Asimismo, el proyecto debe considerar las disposiciones en materia de eficiencia energética y uso sostenible de recursos, promoviendo el uso de tecnologías que minimicen el consumo energético y reduzcan la huella ambiental del sistema. Aunque estos aspectos no siempre están regulados por una norma específica, forman parte de las mejores prácticas en el diseño de infraestructura hidráulica moderna. En la Tabla 4.5 se presenta el resumen del marco normativo aplicable al sistema de abastecimiento de agua potable.

El cumplimiento de este marco normativo debe integrarse desde la etapa de diseño conceptual, de manera que las soluciones técnicas adoptadas sean compatibles con los requisitos legales y regulatorios. Esto implica no solo diseñar infraestructura que cumpla con las normas, sino también establecer procedimientos operativos, programas de monitoreo y sistemas de control que permitan mantener el cumplimiento a lo largo del tiempo.

En conclusión, el aspecto normativo del sistema de abastecimiento de agua potable no debe considerarse como un elemento externo o posterior al diseño, sino como un componente estructural que condiciona la definición técnica del proyecto. Su adecuada integración garantiza la seguridad sanitaria, la sostenibilidad del recurso y la viabilidad legal del sistema dentro del desarrollo portuario de Cuyutlán.

Tabla 4.5 Normativa.

NORMA / INSTRUMENTO	ALCANCE	APLICACIÓN EN EL PROYECTO
NOM-127-SSA1-2021	Calidad del agua potable	Diseño del tratamiento y control de calidad
NOM-230-SSA1-2002	Requisitos sanitarios	Operación, mantenimiento y monitoreo
NOM-001-CONAGUA-2011	Hermeticidad de redes	Diseño y construcción de la red
Ley de Aguas Nacionales	Uso de aguas nacionales	Concesión y explotación del pozo
Reglamentos de CONAGUA	Construcción de pozos	Diseño y operación del pozo
Disponibilidad de acuíferos	Balance hídrico	Viabilidad del abastecimiento
Normativa ambiental	Protección ambiental	Manejo de descargas y residuos

Fuente: Elaboración propia, RHG Ingeniería, 2026.

4.5 Consideraciones operativas

El sistema debe diseñarse con un enfoque de operación continua, incluyendo respaldo eléctrico, mantenimiento programado y monitoreo en tiempo real. La separación entre agua potable y agua para servicios no potables debe considerarse desde la fase conceptual, con el fin de optimizar costos y eficiencia del sistema.

La automatización del sistema permitirá reducir riesgos operativos y facilitar la toma de decisiones, particularmente en situaciones de contingencia o variación en la calidad del agua.

En síntesis el sistema de suministro de agua potable para el desarrollo portuario de Cuyutlán debe concebirse como una infraestructura crítica, diseñada bajo principios de redundancia, modularidad y adaptabilidad. La integración adecuada entre el pozo de abastecimiento, la planta potabilizadora y la red de distribución garantiza la viabilidad operativa del puerto y el cumplimiento de los estándares sanitarios.

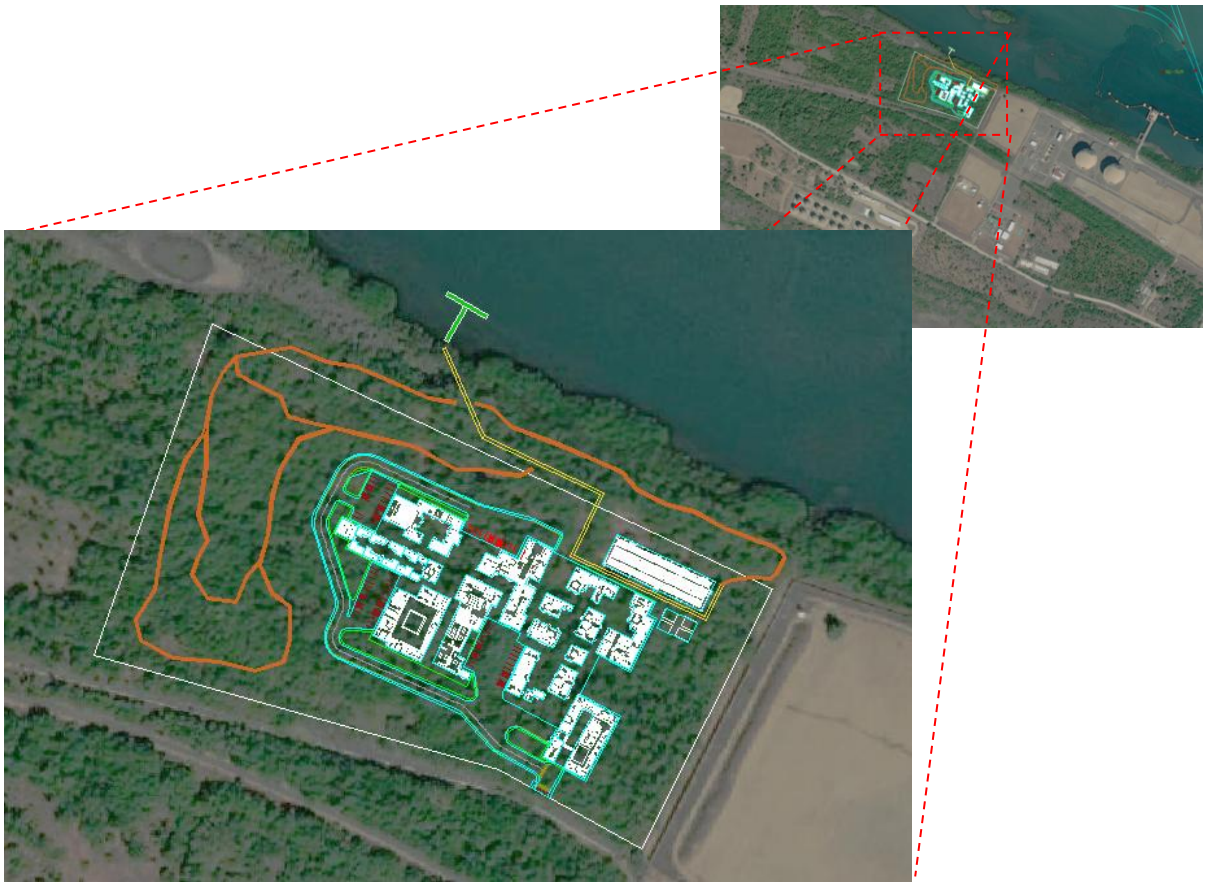
El cumplimiento del marco normativo y la incorporación de criterios técnicos adecuados desde la etapa conceptual permitirán desarrollar un sistema robusto, capaz de operar de manera eficiente en un entorno complejo y exigente como el de la Laguna de Cuyutlán.

5.0 CENTRO DE INVESTIGACIÓN AMBIENTAL PORTUARIO.

El presente capítulo describe técnica y conceptualmente la propuesta del Centro de Investigación Ambiental Portuario (CIAP). El CIAP se concibe como una infraestructura estratégica para apoyar el desarrollo del Puerto Nuevo Manzanillo, integrando investigación científica, monitoreo ambiental, operación de campo, conservación ecológica y vinculación social.

Su prediseño responde a las condiciones particulares del sistema lagunar–costero, caracterizado por alta sensibilidad ambiental, dinámica hidrosedimentológica compleja y creciente presión por actividades portuarias.

Figura 5.1 Localización del CIAP.



Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.1 Criterios Generales de Planeación

El planteamiento del (CIAP) se fundamenta en un conjunto de criterios de planeación que integran variables territoriales, ambientales, operativas, normativas y de crecimiento a largo plazo, propias de una infraestructura científica estratégica localizada en un sistema lagunar–costero con interacción directa con actividades portuarias. Estos criterios constituyen la base del anteproyecto y definen las condiciones bajo las cuales el conjunto debe evolucionar hacia etapas posteriores de ingeniería.

Desde el punto de vista territorial, el rango de superficie del predio, establecido entre 30,000 y 50,000 m², no responde únicamente a una disponibilidad de suelo, sino a la necesidad de garantizar distancias operativas, separación funcional entre edificios, amortiguamiento ambiental, reservas para crecimiento y compatibilidad con usos exteriores como viveros, senderos interpretativos, patios técnicos, vialidades internas y zonas de restauración ecológica. Este dimensionamiento permite evitar configuraciones compactas que comprometan la bioseguridad, la operación simultánea de múltiples procesos y la adaptación a condiciones climáticas propias de la zona costera. Para nuestro caso y de acuerdo con la disponibilidad de terrenos en la zona de proyecto el CIAP se desarrollará en una superficie de 76,848.46 m^2.

La superficie construida estimada de 29,218.16 m² se establece como una cifra de control que equilibra la capacidad científica, operativa y de vinculación del centro con la viabilidad técnica y económica del proyecto. Esta superficie no debe entenderse como un límite rígido, sino como una referencia base que permite dimensionar instalaciones, redes de servicio, cargas estructurales, consumos energéticos y requerimientos hidráulicos. Su definición se sustenta en la integración de diez unidades funcionales con distintos niveles de criticidad, desde laboratorios altamente especializados hasta áreas públicas y de apoyo, lo cual exige una distribución espacial que minimice interferencias y optimice flujos.

En términos de capacidad operativa, el rango de 50 a 70 personas en operación simultánea se adopta como parámetro de diseño para dimensionar áreas de trabajo, servicios sanitarios, sistemas de ventilación, consumos de agua, cargas eléctricas, rutas de evacuación y estacionamientos. Este valor incorpora no sólo al personal permanente, sino también a investigadores visitantes, técnicos de campo, personal de mantenimiento y usuarios de áreas de vinculación. Desde una perspectiva normativa, este parámetro se vincula con criterios de ocupación, seguridad y habitabilidad establecidos en reglamentos de construcción, normas de protección civil y estándares de diseño de espacios laborales y educativos.

El horizonte de crecimiento de veinte años constituye un criterio estructural del anteproyecto, ya que obliga a plantear un esquema de implantación modular y escalable. Este horizonte no sólo responde a una proyección temporal, sino a la expectativa de incremento en la complejidad de las actividades científicas, la incorporación de nuevas líneas de investigación, el

aumento en la instrumentación tecnológica y la ampliación de capacidades de monitoreo ambiental. En consecuencia, la planeación debe prever reservas territoriales, sobredimensionamiento estratégico de redes primarias (eléctricas, hidráulicas y de telecomunicaciones) y una traza urbana interna que permita ampliaciones sin afectar la operación existente.

El esquema de desarrollo por etapas representa una estrategia técnica para gestionar inversión, riesgo y maduración funcional del centro. La secuencia planteada, que inicia con un núcleo operativo, continúa con la consolidación científica y culmina con la vinculación pública y residencia, responde a una lógica de priorización en la que primero se asegura la capacidad de generación de información y operación de campo, posteriormente se amplían las capacidades de análisis y restauración, y finalmente se fortalece la interacción con la sociedad y la comunidad científica. Este enfoque se alinea con metodologías de planeación de infraestructura estratégica y con criterios de implementación progresiva utilizados en proyectos portuarios y centros de investigación de gran escala.

La configuración del conjunto mediante edificios independientes pero articulados se fundamenta en principios de ingeniería funcional, bioseguridad y resiliencia. La separación física entre unidades permite controlar riesgos asociados a contaminación cruzada, manejo de reactivos, presencia de fauna, operación de maquinaria y tránsito de usuarios externos. Al mismo tiempo, la articulación mediante plazas, andadores, patios técnicos y vialidades internas garantiza conectividad operativa, eficiencia logística y legibilidad espacial del conjunto. Esta configuración es consistente con criterios internacionales de diseño de campus científicos y con recomendaciones para instalaciones en ambientes con riesgos diferenciados.

Desde el punto de vista ambiental y climático, la planeación del CIAP debe responder a condiciones de alta humedad, salinidad, radiación solar intensa y eventos meteorológicos extremos. La disposición de edificios separados favorece la ventilación natural, reduce la acumulación de calor y permite orientar adecuadamente cada volumen para minimizar el asoleamiento crítico. Este criterio se alinea con estrategias de diseño bioclimático y eficiencia energética, que buscan reducir la dependencia de sistemas mecánicos en áreas no críticas, al tiempo que concentran los recursos de climatización en espacios que realmente lo requieren, como laboratorios y centros de datos.

La resiliencia del conjunto ante condiciones costeras constituye otro eje fundamental de planeación. Esto implica considerar desde esta etapa la elevación de plataformas respecto a niveles de inundación, la definición de pendientes y escurrimientos, la protección de instalaciones críticas, la redundancia en sistemas de energía y datos, y la capacidad de mantener operación parcial o total ante eventos extremos. Estos criterios se sustentan en prácticas de diseño resiliente para infraestructura crítica, así como en lineamientos derivados de la gestión de riesgos en zonas costeras y portuarias.

En términos normativos, la planeación del CIAP debe integrarse con el marco regulatorio aplicable en materia de construcción, medio ambiente, seguridad, accesibilidad y operación de instalaciones científicas. Esto incluye, de manera no limitativa, reglamentos de construcción locales, normas oficiales mexicanas relacionadas con seguridad e higiene, manejo de residuos, calidad del agua, accesibilidad universal, así como lineamientos de protección civil y, en su caso, referencias internacionales aplicables a laboratorios, instalaciones de monitoreo y centros de datos. La incorporación temprana de estos criterios evita rediseños en etapas posteriores y asegura que el anteproyecto sea técnicamente viable desde su origen.

Para sintetizar los principales parámetros de planeación se presentan en la Tabla 5.1, la cual sirve como referencia para la toma de decisiones en etapas subsecuentes:

Tabla 5.1 Parámetros de Planeación del CIAP.

PARÁMETRO	VALOR DE REFERENCIA	BASE TÉCNICA	IMPLICACIÓN DE DISEÑO
Superficie del predio	50,000 – 70,000 m²	Separación funcional, crecimiento, áreas exteriores	Permite campus abierto y modular
Superficie construida	15,500 m²	Balance entre capacidad y viabilidad	Dimensiona redes y estructuras
Capacidad operativa	50 – 70 personas	Ocupación, servicios, seguridad	Define instalaciones y evacuación
Horizonte de crecimiento	20 años	Escalabilidad y evolución científica	Requiere reservas y redes sobredimensionadas
Desarrollo por etapas(1)	3 fases	Gestión de inversión y maduración funcional	Permite implementación progresiva
Configuración	Edificios separados articulados	Bioseguridad, resiliencia, ventilación	Evita interferencias operativas

Nota: (1) Lo recomendable es implementar el CIAP en una sola fase, pero depende de los recursos que le sean destinados.
Fuente: Elaboración propia, RHG Ingeniería, 2026.

En conjunto, estos criterios establecen un marco técnico sólido para el desarrollo del CIAP, asegurando que el anteproyecto no sólo responda a un programa arquitectónico, sino que integre las condiciones reales del sitio, las exigencias operativas del sistema portuario y los requerimientos de una infraestructura científica de largo plazo.

5.2 Justificación Técnica del Centro.

La justificación técnica del CIAP se fundamenta en la necesidad de contar con una infraestructura especializada que permita integrar, de manera continua y sistemática, información

científica, operativa y ambiental para la toma de decisiones en el desarrollo y operación del Puerto Nuevo Manzanillo. La Laguna de Cuyutlán constituye un sistema lagunar–costero altamente sensible, en el que convergen procesos hidrodinámicos, sedimentológicos, ecológicos y antrópicos, por lo que cualquier intervención asociada a infraestructura portuaria requiere soporte técnico permanente, validado y trazable.

En este contexto, el CIAP no debe entenderse como un equipamiento complementario, sino como un componente estructural del sistema portuario, cuya función es reducir incertidumbre, anticipar impactos, optimizar diseños y garantizar el cumplimiento de condicionantes ambientales y operativas.

5.2.1 Soporte a la Infraestructura Portuaria.

El desarrollo portuario en ambientes lagunares implica modificaciones sustanciales en la morfología del sistema, incluyendo dragados, rellenos, construcción de dársenas, canales de navegación, escolleras y obras de protección. Estas intervenciones alteran los patrones de circulación, transporte de sedimentos, intercambio hidráulico y calidad del agua, por lo que su diseño y operación deben sustentarse en información técnica actualizada y validada.

El CIAP proporciona la base científica para este soporte mediante la integración de modelación numérica, monitoreo en campo y análisis de laboratorio. Desde el punto de vista de ingeniería, esto permite establecer condiciones de frontera, calibrar modelos hidrodinámicos, validar escenarios de diseño y evaluar el comportamiento del sistema ante distintas configuraciones de obra. La referencia conceptual para este tipo de análisis se encuentra en metodologías de ingeniería portuaria y costera ampliamente utilizadas, como las recomendaciones PIANC (Permanent International Association of Navigation Congresses) y manuales de ingeniería costera, que establecen la necesidad de estudios integrales previos y durante la operación de infraestructura marítima.

Asimismo, el soporte técnico continuo permite ajustar estrategias de dragado, definir programas de mantenimiento, optimizar alineamientos de canales y reducir riesgos de azolvamiento o erosión no controlada. En ausencia de este tipo de infraestructura científica, las decisiones de ingeniería se basan en información puntual o desactualizada, incrementando la probabilidad de sobrecostos, fallas operativas o impactos ambientales no previstos.

5.2.2 Monitoreo Ambiental Permanente.

El monitoreo ambiental permanente constituye uno de los pilares técnicos del CIAP, ya que permite caracterizar la línea base del sistema, detectar cambios en el tiempo y evaluar la efectividad de medidas de mitigación. En un sistema como la Laguna de Cuyutlán, donde coexisten humedales, cuerpos de agua someros, intercambio con el mar y actividades industriales, el monitoreo debe ser continuo, multivariable y espacialmente representativo.

La base de diseño de este componente se sustenta en la integración de estaciones de monitoreo, sensores en tiempo real, campañas de muestreo y análisis de laboratorio, cubriendo variables como calidad del agua, parámetros fisicoquímicos, contaminantes, sedimentos, biodiversidad y condiciones meteorológicas. Este enfoque responde a lineamientos establecidos en evaluaciones de impacto ambiental y normas oficiales mexicanas relacionadas con calidad del agua, descargas y protección de ecosistemas, así como a buenas prácticas internacionales en monitoreo ambiental.

El carácter permanente del monitoreo permite generar series de tiempo que son fundamentales para la calibración de modelos, la identificación de tendencias y la detección temprana de anomalías. Además, facilita la trazabilidad de datos, requisito clave en procesos regulatorios y auditorías ambientales. Desde la perspectiva operativa, la disponibilidad de información en tiempo real permite establecer umbrales de alerta y activar protocolos de respuesta ante eventos como incrementos en turbidez, presencia de contaminantes o cambios abruptos en parámetros críticos.

En la Tabla 5.2 se resumen las principales variables de monitoreo y su implicación técnica:

Tabla 5.2 Variables de Monitoreo.

VARIABLE	BASE TÉCNICA	APLICACIÓN EN EL CIAP
Calidad del agua	Normas de calidad y descarga	Evaluación de impacto y cumplimiento ambiental
Sedimentos	Transporte y deposición	Control de azolvamiento y dragado
Meteorología	Interacción atmósfera–cuerpo de agua	Pronóstico y operación portuaria
Biodiversidad	Indicadores ecológicos	Seguimiento de impactos y restauración
Contaminantes	Riesgos ambientales	Detección y control de derrames

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.2.3 Gestión de Riesgos y Contingencias.

La operación de infraestructura portuaria en un entorno lagunar conlleva riesgos asociados a eventos naturales, fallas operativas y contingencias ambientales. Entre estos se

incluyen derrames de hidrocarburos, eventos meteorológicos extremos, fallas en infraestructura hidráulica, contaminación accidental y afectaciones a fauna.

El CIAP se concibe como un elemento clave en la gestión de estos riesgos, al integrar capacidades de monitoreo, análisis, modelación y respuesta técnica. Desde el punto de vista de ingeniería, esto implica contar con sistemas que permitan identificar condiciones de riesgo, evaluar su evolución y definir acciones correctivas en tiempo oportuno.

La base conceptual de este enfoque se encuentra en la gestión integral de riesgos, que combina identificación, análisis, evaluación y mitigación, así como en lineamientos de protección civil y continuidad operativa. El centro de monitoreo y la sala de crisis juegan un papel fundamental en este esquema, al concentrar información, coordinar respuestas y facilitar la comunicación entre actores institucionales.

El diseño del CIAP debe permitir que estas funciones se desarrollen sin interrupciones, lo que justifica la incorporación de sistemas redundantes de energía, telecomunicaciones y acceso a datos. Asimismo, la proximidad funcional entre monitoreo, laboratorios y operación de campo reduce tiempos de respuesta y mejora la eficacia de las acciones implementadas.

5.2.4 Vinculación social y cumplimiento normativo

La vinculación social y el cumplimiento normativo constituyen componentes estratégicos en proyectos de infraestructura portuaria, particularmente en contextos donde existen comunidades cercanas, ecosistemas sensibles y alta visibilidad pública.

El CIAP integra estas funciones a través de espacios de educación ambiental, difusión científica y participación social, lo que permite comunicar resultados, transparentar información y fortalecer la relación con comunidades, instituciones académicas y autoridades. Desde una perspectiva técnica, esto contribuye a la aceptación social del proyecto y reduce riesgos asociados a conflictos o retrasos por falta de información.

En términos normativos, el centro facilita el cumplimiento de condicionantes establecidas en evaluaciones de impacto ambiental, autorizaciones y permisos, al proporcionar evidencia técnica verificable sobre el estado del sistema y la efectividad de las medidas implementadas. Este soporte es fundamental en auditorías ambientales, inspecciones y procesos de seguimiento regulatorio.

El enfoque de vinculación también se alinea con tendencias internacionales en gestión de infraestructura, que promueven la transparencia, la participación informada y la integración de conocimiento científico en la toma de decisiones públicas. En la siguiente tabla se sintetiza la relación entre estas funciones y su impacto técnico.

Tabla 5.3 Vinculación Social y Cumplimiento Normativo.

COMPONENTE	BASE TÉCNICA	IMPACTO EN EL PROYECTO
Educación ambiental	Difusión científica	Mejora de percepción social
Participación social	Gestión de actores	Reducción de conflictos
Cumplimiento normativo	Regulación ambiental	Viabilidad legal del proyecto
Transparencia de datos	Trazabilidad	Confianza institucional

Fuente: Elaboración propia, RHG Ingeniería, 2026.

En conjunto, estos elementos consolidan la justificación del CIAP como una infraestructura esencial para garantizar que el desarrollo portuario en la Laguna de Cuyutlán se lleve a cabo bajo criterios de sostenibilidad, eficiencia operativa y responsabilidad ambiental.

5.3 Estructura Funcional del Centro

La estructura funcional del Centro de Investigación Ambiental Portuario (CIAP) se organiza como un sistema integrado de unidades especializadas que operan de manera coordinada bajo criterios de segregación funcional, bioseguridad, continuidad operativa y eficiencia logística, en un área de 76,848.46 m2, de los cuales el 38% (29,218.16 m^2) se encuentra urbanizado y el restante 62% (47,630.30 m2) será destinado a un área de conservación y educación ecológica. Asimismo, contará con 1,332.09 m de senderos dedicados a la educación ecológica y difusión ambiental, ver Tabla 5.4.

Cada edificio responde a una función técnica específica dentro del ciclo completo de generación de información, análisis, toma de decisiones, operación de campo, conservación ambiental y vinculación social.

El diseño funcional se fundamenta en principios de ingeniería de procesos, donde se identifican flujos de información, materiales, personal y energía, estableciendo relaciones espaciales que minimicen interferencias y maximicen la eficiencia operativa. Asimismo, se consideran referencias conceptuales de diseño de campus científicos, instalaciones portuarias y centros de investigación ambiental.

5.3.1 Edificio Administrativo y Dirección.

El edificio administrativo constituye el núcleo de gestión estratégica, operativa y normativa del CIAP. Su función principal es coordinar las actividades científicas, técnicas, financieras y de vinculación, asegurando la alineación con los objetivos del proyecto portuario.

Tabla 5.4 Distribución de Áreas del CIAP.

INSTALACIÓN		ÁREA m²
Edificio Administrativo		1,377.50
Laboratorios	Sedimentos	94.81
	Biología	102.28
	Microbiología	105.34
	Recepción de muestras	120.48
	Calidad del agua	120.48
	SIG y Modelación	114.81
	Pretratamiento y lavado	114.81
	Preparación de Medios	120.48
	Reactivos	120.48
	Química	170.14
	Recepción de fauna	431.67
	Botánico	271.75
	Vivero	1,521.10
	Unidad de conservación ecológica	315.85
	Zona de investigadores	2,312.22

Muelle de madera (m)		30.00
Plataforma peatonal de madera (m)		339.46

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Desde el punto de vista técnico, este edificio opera como centro de control institucional, integrando procesos de toma de decisiones, gestión documental, cumplimiento regulatorio y coordinación interinstitucional. La base de diseño considera criterios de funcionalidad, flexibilidad y conectividad digital, permitiendo la integración con sistemas de monitoreo, laboratorios y plataformas de datos.

El personal estimado en esta unidad incluye dirección general, coordinación técnica, administración, recursos humanos, área jurídica ambiental y soporte administrativo, con una ocupación aproximada de 10 a 15 personas en operación simultánea.

5.3.2 Laboratorios e Investigación.

Los edificios de laboratorios es el núcleo científico del CIAP y concentra las funciones analíticas y de generación de conocimiento técnico. Su diseño se basa en la segregación de procesos, control ambiental, seguridad química y trazabilidad analítica, conforme a buenas prácticas de laboratorio y lineamientos normativos en materia de seguridad e higiene.

Las funciones de los principales laboratorios se describen en la tabla 5.5

Tabla 5.5 Distribución de Laboratorios.

LABORATORIO	FUNCIÓN TÉCNICA	PERSONAL ESTIMADO
Calidad de agua	Análisis fisicoquímico (pH, DBO, DQO, nutrientes)	3–4 químicos/ambientales
Sedimentos	Caracterización granulométrica y contaminantes	2–3 geólogos/ingenieros
Biología / biota	Evaluación de organismos y biodiversidad	3 biólogos
Microbiología	Análisis microbiológico y sanitario	2–3 especialistas
Contaminantes / química analítica	Metales, hidrocarburos, compuestos orgánicos	3–4 químicos
SIG y modelación	Análisis espacial y simulación ambiental	3 analistas

Fuente: Elaboración propia, RHG Ingeniería, 2026.

a. El laboratorio de calidad de agua constituye uno de los núcleos analíticos principales del CIAP, ya que permite caracterizar el estado fisicoquímico del sistema lagunar y su interacción con las actividades portuarias. Su función consiste en la determinación de parámetros como pH, conductividad, oxígeno disuelto, demanda bioquímica y química

de oxígeno (DBO y DQO), sólidos suspendidos, nutrientes (nitrógeno y fósforo) y otros indicadores de calidad. Estos análisis son fundamentales para evaluar el cumplimiento de normas ambientales, detectar procesos de eutrofización, identificar descargas contaminantes y establecer líneas base ambientales. Desde el punto de vista técnico, este laboratorio soporta tanto el monitoreo rutinario como la validación de modelos de calidad del agua y estudios de impacto ambiental.

b. El laboratorio de sedimentos tiene como función analizar las características físicas, químicas y, en ciertos casos, mineralógicas de los sedimentos del sistema lagunar y de las áreas de dragado. Este laboratorio permite determinar granulometría, contenido de materia orgánica, capacidad de retención de contaminantes y presencia de metales pesados o hidrocarburos adsorbidos. Su relevancia técnica radica en que los sedimentos actúan como reservorios de contaminantes y son un factor clave en procesos de azolvamiento, erosión y estabilidad de obras portuarias. La información generada es esencial para definir estrategias de dragado, disposición de materiales y evaluación de riesgos ambientales asociados a la remoción de sedimentos.

c. El laboratorio de biología o biota se enfoca en el estudio de los organismos presentes en el sistema lagunar, incluyendo fitoplancton, zooplancton, bentos y, en algunos casos, ictiofauna en etapas tempranas. Su función principal es evaluar la biodiversidad, estructura de comunidades y posibles alteraciones derivadas de actividades antropogénicas. Este laboratorio permite identificar cambios en la composición biológica que pueden ser indicadores tempranos de deterioro ambiental. Desde el punto de vista técnico, su operación se vincula con metodologías de bioindicadores y evaluación ecológica, fundamentales en estudios de impacto ambiental y programas de monitoreo de largo plazo.

d. El laboratorio de microbiología tiene como objetivo analizar la presencia de microorganismos, particularmente aquellos asociados a contaminación fecal o riesgos sanitarios, como coliformes totales y fecales, enterococos y otros indicadores microbiológicos. Su función es crítica para evaluar la calidad sanitaria del agua, especialmente en zonas con interacción humana o riesgo de descargas. Este laboratorio también puede apoyar en la detección de procesos biológicos que influyen en la degradación de materia orgánica. Desde una perspectiva normativa, sus resultados son clave para el cumplimiento de estándares de calidad del agua y para la evaluación de riesgos a la salud.

e. El laboratorio de contaminantes o química analítica se encarga de la identificación y cuantificación de compuestos específicos de interés ambiental, como metales pesados (mercurio, plomo, cadmio), hidrocarburos totales del petróleo, compuestos orgánicos persistentes y otras sustancias potencialmente tóxicas. Este laboratorio requiere instrumentación especializada, como cromatografía y espectrometría, y su función es

esencial para la detección de contaminación puntual o difusa asociada a actividades portuarias, industriales o de transporte marítimo. Técnicamente, este laboratorio permite realizar evaluaciones de riesgo ambiental, estudios de dispersión de contaminantes y verificación de cumplimiento de límites permisibles establecidos en normativa ambiental.

f. La sala de sistemas de información geográfica (SIG) y modelación ambiental funciona como un laboratorio de análisis digital en el que se integran datos espaciales, resultados de laboratorio y mediciones de campo para generar modelos predictivos y escenarios de simulación. Su función es transformar datos en información útil para la toma de decisiones, mediante herramientas de análisis espacial, teledetección y modelación hidrodinámica o ambiental. Este espacio es fundamental para entender la dinámica del sistema lagunar en su conjunto, evaluar impactos de obras portuarias y apoyar la planeación de intervenciones.

g. La sala de interpretación de imágenes y teledetección complementa al SIG mediante el procesamiento de imágenes satelitales, fotografías aéreas y datos remotos. Su función es detectar cambios en cobertura vegetal, turbidez del agua, evolución de líneas de costa y otros indicadores ambientales a escala regional. Este laboratorio permite ampliar la cobertura del monitoreo más allá de los puntos de muestreo, integrando una visión espacial continua del sistema.

h. Finalmente, la sala de preparación de muestras y áreas de apoyo analítico cumplen una función transversal dentro del edificio de laboratorios. En estos espacios se realizan procesos de pretratamiento, filtrado, conservación, etiquetado y registro de muestras, asegurando la trazabilidad y calidad de los análisis posteriores. Técnicamente, estas áreas son fundamentales para garantizar que los resultados generados en los distintos laboratorios sean confiables y reproducibles, conforme a principios de buenas prácticas de laboratorio.

El conjunto de laboratorios se espera operé con una plantilla aproximada de 20 a 30 personas entre investigadores, técnicos y becarios. Su diseño debe cumplir con criterios de ventilación controlada, presión diferencial, materiales resistentes a químicos y sistemas de manejo de residuos peligrosos.

5.3.3 Centro de Monitoreo Ambiental y Datos.

El centro de monitoreo funciona como el nodo de integración de información en tiempo real, procesando datos provenientes de sensores, estaciones de campo y laboratorios. Su diseño se basa en principios de infraestructura crítica, con requerimientos de alta disponibilidad, redundancia y seguridad.

Este centro alberga operadores, analistas de datos, especialistas en modelación y personal de tecnologías de la información, con una ocupación estimada de 8 a 12 personas por turno. La base técnica incluye sistemas de respaldo energético, climatización de precisión, telecomunicaciones redundantes y control de acceso.

5.3.4 Edificio de Educación Ambiental y Vinculación.

Este edificio constituye la interfaz del CIAP con la sociedad, integrando funciones de difusión, capacitación y participación social. Su diseño responde a criterios de accesibilidad universal, seguridad en espacios públicos y flexibilidad de uso.

El personal incluye educadores ambientales, comunicadores, personal de atención y coordinación institucional, con una ocupación estimada de 8 a 15 personas dependiendo de la operación.

5.3.5 Alojamiento para Investigadores.

El alojamiento permite la estancia temporal de investigadores y técnicos, facilitando campañas intensivas y colaboración externa. Su diseño se basa en criterios de habitabilidad, autonomía y cercanía funcional con áreas técnicas.

Se estima una capacidad de 18 a 24 usuarios simultáneos, incluyendo investigadores visitantes y personal operativo.

5.3.6 Talleres, Almacenes y Servicios Técnicos

Esta unidad proporciona soporte logístico y de mantenimiento a todas las áreas del CIAP. Incluye talleres, almacenes y espacios de preparación de campañas.

El personal estimado es de 6 a 10 técnicos especializados en mantenimiento, logística y operación de equipos.

5.3.7 Unidad de Conservación Ecológica y Vivero

La unidad de vivero tiene como función la producción de especies vegetales para restauración ecológica. Su diseño se basa en criterios de control ambiental, disponibilidad de agua y adaptación de especies.

El personal incluye biólogos, agrónomos y técnicos, con una ocupación estimada de 6 a 10 personas.

5.3.8 Unidad de Rescate y Manejo de Fauna.

Esta unidad permite la atención, rehabilitación y manejo temporal de fauna afectada por actividades portuarias. Su diseño responde a criterios de bioseguridad, sanidad y bienestar animal.

El personal estimado incluye veterinarios y biólogos, con una ocupación de 4 a 6 personas.

5.3.9 Embarcadero y Apoyo Operativo.

El embarcadero es la interfaz operativa entre el centro y la laguna, permitiendo actividades de monitoreo y muestreo en campo. Su diseño considera condiciones hidráulicas, seguridad y logística de operación.

El personal incluye operadores de campo y técnicos, con una ocupación de 4 a 8 personas.

5.3.10 Obras Complementarias.

Las obras complementarias integran la infraestructura técnica necesaria para la operación del CIAP, incluyendo sistemas eléctricos, hidráulicos y de servicios generales. Su diseño se basa en criterios de redundancia, accesibilidad y seguridad.

El personal asociado corresponde a mantenimiento e instalaciones, con una ocupación de 3 a 6 personas.

5.4 Personal y Capacidad Operativa

La definición del personal y la capacidad operativa del CIAP constituye un elemento crítico del anteproyecto, ya que establece la base para el dimensionamiento de espacios, sistemas, turnos de operación, cargas de servicios e interacciones funcionales entre las distintas unidades. La estructura de personal se fundamenta en un enfoque multidisciplinario, propio de instalaciones científicas asociadas a sistemas portuarios y ambientales, en donde convergen actividades analíticas, operativas, logísticas y de gestión.

El rango de ocupación simultánea de 50 a 70 personas responde a un equilibrio entre capacidad técnica, eficiencia operativa y viabilidad de infraestructura, considerando personal permanente, usuarios temporales, investigadores visitantes y personal de campo.

Desde el punto de vista técnico, la estructura de personal debe alinearse con principios de operación continua, segregación de funciones, trazabilidad de procesos y cumplimiento normativo en materia laboral, ambiental y de seguridad. Esto implica definir perfiles especializados, jerarquías claras y esquemas de coordinación que permitan integrar información desde campo hasta toma de decisiones.

5.4.1 Personal técnico y científico

El personal técnico y científico constituye el núcleo de generación de conocimiento del CIAP, siendo responsable de la adquisición, análisis, interpretación y validación de información ambiental y portuaria. Su integración responde a criterios de especialización disciplinaria, capacidad analítica y experiencia en sistemas costeros y lagunares.

Los perfiles principales se estructuran en torno a las disciplinas clave del centro, incluyendo ingeniería ambiental, oceanografía, biología, química, geotecnia y análisis espacial. Estos perfiles deben cumplir con estándares de formación profesional, experiencia en laboratorio o campo y, en su caso, acreditaciones o certificaciones conforme a normas de calidad analítica y buenas prácticas de laboratorio. En la Tabla 5.6 se sintetiza los perfiles técnicos y sus funciones.

Tabla 5.6 Personal Técnico y Científico.

PERFIL	FORMACIÓN BASE	FUNCIÓN PRINCIPAL	INTERACCIÓN FUNCIONAL
Ingeniero ambiental	Ingeniería ambiental o afín	Evaluación de impacto y análisis de sistemas	Laboratorios, monitoreo, dirección
Oceanógrafo / Ing. Marítimo Portuario	Oceanografía, hidráulica o afín	Modelación y análisis de dinámica lagunar	Monitoreo, datos, planeación
Químico analista	Química o química ambiental	Análisis de contaminantes y calidad del agua	Laboratorios, control de calidad
Biólogo	Biología, ecología	Evaluación de biodiversidad y fauna	Vivero, rescate, monitoreo
Especialista SIG	Geomática, geografía	Análisis espacial y teledetección	Datos, modelación, planeación
Microbiólogo	Microbiología	Análisis sanitario y biológico	Laboratorios, calidad del agua

Fuente: Elaboración propia, RHG Ingeniería, 2026.

El número estimado de personal técnico y científico se sitúa entre 20 y 30 personas, considerando investigadores principales, técnicos especializados y personal en formación. Este grupo constituye el eje central del CIAP y determina en gran medida la capacidad analítica y científica del centro.

Desde una perspectiva normativa, este personal debe operar bajo esquemas de aseguramiento de calidad, trazabilidad de resultados y cumplimiento de normas oficiales mexicanas relacionadas con análisis ambiental, manejo de sustancias químicas y seguridad en el trabajo.

5.4.2 Personal operativo

El personal operativo es responsable de la ejecución de actividades de campo, mantenimiento de equipos, operación de sistemas de monitoreo y soporte directo a las actividades científicas. Su función es garantizar la continuidad de los procesos técnicos, la disponibilidad de equipos y la correcta implementación de campañas de muestreo, ver Tabla 5.7.

Tabla 5.7 Personal Operativo.

PERFIL	FORMACIÓN BASE	FUNCIÓN PRINCIPAL	ÁREA DE OPERACIÓN
Técnico de laboratorio	Técnico químico o afín	Preparación de muestras y apoyo analítico	Laboratorios
Operador de monitoreo	Técnico en sistemas o ambiental	Supervisión de datos en tiempo real	Centro de monitoreo
Técnico de campo	Técnico ambiental o similar	Muestreo y levantamiento de datos	Laguna y entorno
Operador de embarcaciones	Náutica o experiencia certificada	Maniobra y operación de lanchas	Embarcadero
Técnico de mantenimiento	Electromecánico	Mantenimiento de equipos e instalaciones	Talleres y servicios

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Este grupo incluye técnicos de laboratorio, operadores de monitoreo, personal de campo, operadores de embarcaciones y personal de mantenimiento especializado. Su perfil se caracteriza por formación técnica, experiencia práctica y conocimiento de protocolos de operación y seguridad.

La base de diseño de este grupo se sustenta en la necesidad de mantener operativos sistemas críticos, incluyendo sensores, estaciones de monitoreo, equipos analíticos y embarcaciones, así como en la capacidad de respuesta ante eventos o contingencias.

El personal operativo se estima entre 15 y 25 personas, dependiendo de la intensidad de las actividades de campo y del nivel de automatización de los sistemas. Este grupo es clave para garantizar la funcionalidad diaria del CIAP y su capacidad de respuesta.

5.4.3 Personal de soporte

El personal de soporte integra las funciones administrativas, logísticas, tecnológicas y de servicios generales necesarias para el funcionamiento integral del centro. Aunque no participa directamente en actividades científicas, su rol es esencial para asegurar la continuidad operativa, el cumplimiento normativo y la gestión eficiente de recursos.

Este grupo incluye personal administrativo, tecnologías de la información, seguridad, limpieza, servicios generales y apoyo institucional. Su diseño se basa en criterios de eficiencia organizacional, control de recursos y soporte a procesos críticos. En la tabla 5.8 se muestra una síntesis de los perfiles.

Tabla 5.8 Personal de Soporte o Administrativo.

PERFIL	FORMACIÓN BASE	FUNCIÓN PRINCIPAL	ÁREA DE SOPORTE
Administrativo	Administración	Gestión de recursos y control operativo	Dirección
TI / telecomunicaciones	Ingeniería en sistemas	Soporte a redes, datos y sistemas	Monitoreo, datos
Seguridad	Seguridad industrial	Control de accesos y protección	Accesos, instalaciones
Servicios generales	Operativo	Limpieza y apoyo logístico	Todo el centro
Jurídico / normativo	Derecho ambiental	Cumplimiento regulatorio	Dirección

Fuente: Elaboración propia, RHG Ingeniería, 2026.

El personal de soporte se estima entre 10 y 15 personas, dependiendo del nivel de externalización de servicios. Su función es garantizar que las actividades técnicas y operativas se desarrollen en un entorno controlado, seguro y conforme a la normatividad aplicable.

En conjunto, la estructura de personal del CIAP se organiza como un sistema integrado en el que cada grupo cumple funciones específicas pero interdependientes, permitiendo que el centro opere de manera continua, eficiente y alineada con los objetivos del proyecto portuario y ambiental.

5.5 Etapas de Desarrollo

La definición de las etapas de desarrollo del CIAP responde a una estrategia de implementación progresiva basada en criterios de ingeniería, gestión de inversión, maduración funcional y reducción de riesgos operativos. Este enfoque permite que el centro entre en operación de manera temprana con capacidades esenciales, mientras se consolidan y expanden sus funciones conforme evolucionan las necesidades del sistema portuario y ambiental.

La secuencia de etapas se sustenta en principios de planeación de infraestructura estratégica, en los cuales se prioriza la habilitación de capacidades críticas en fases iniciales, seguidas por la ampliación de capacidades analíticas y, finalmente, la consolidación de funciones de vinculación y soporte extendido. Este modelo es consistente con prácticas internacionales en desarrollo de centros de investigación y plataformas operativas asociadas a sistemas complejos.

a. Etapa 1: Núcleo Operativo.

La primera etapa constituye el núcleo funcional del CIAP y tiene como objetivo habilitar las capacidades mínimas indispensables para iniciar operaciones técnicas, científicas y de campo. Desde el punto de vista de ingeniería, esta fase se orienta a garantizar la operación básica del sistema mediante la implementación de infraestructura crítica y servicios primarios.

En esta etapa se integran los edificios y componentes que permiten la generación de información, su análisis inicial y la ejecución de actividades de monitoreo en campo, incluyendo el edificio administrativo, los laboratorios básicos, el centro de monitoreo ambiental, talleres y almacenes, el embarcadero y las obras de infraestructura primaria.

La base técnica de esta etapa se fundamenta en la necesidad de contar con sistemas operativos autónomos, lo que implica la instalación de redes eléctricas, hidráulicas y de telecomunicaciones con capacidad de expansión, así como la implementación de sistemas de respaldo que aseguren continuidad operativa en condiciones adversas. Asimismo, se deben considerar desde esta fase criterios de resiliencia, tales como elevación de plataformas, drenaje pluvial eficiente y protección de instalaciones críticas.

Desde una perspectiva normativa, esta etapa debe cumplir con los requisitos mínimos de habitabilidad, seguridad estructural, instalaciones y protección civil establecidos en reglamentos de construcción, así como con condicionantes ambientales que permitan el inicio de operaciones del centro.

b. Etapa 2: Consolidación.

La segunda etapa corresponde a la ampliación y especialización de las capacidades científicas y ambientales del CIAP. Su objetivo es consolidar el centro como una plataforma

integral de análisis, restauración y gestión ambiental, incrementando la precisión, cobertura y profundidad de los estudios realizados.

En esta fase se contempla la ampliación de los laboratorios, la implementación de la unidad de conservación ecológica y vivero, la puesta en operación de la unidad de rescate de fauna y el fortalecimiento de la plataforma de monitoreo y análisis de datos.

Desde el punto de vista técnico, esta etapa implica la incorporación de equipamiento especializado, la ampliación de sistemas de control ambiental en laboratorios, el desarrollo de infraestructura para manejo de especies y la integración de procesos de restauración ecológica. Asimismo, se deben reforzar las capacidades de almacenamiento, tratamiento de datos y modelación predictiva.

La base conceptual de esta etapa se vincula con la necesidad de cerrar el ciclo técnico del CIAP, integrando no sólo la generación de información, sino también la implementación de medidas de mitigación y restauración ambiental. Esto es consistente con lineamientos de evaluación de impacto ambiental, en los cuales se establece la obligación de no sólo monitorear, sino también compensar y restaurar los impactos generados.

Desde el punto de vista de diseño, esta etapa debe integrarse de manera armónica con la infraestructura existente, asegurando la compatibilidad de redes, la continuidad de operación y la posibilidad de futuras expansiones.

c. Etapa 3: Vinculación y Residencia

La tercera etapa tiene como objetivo consolidar la dimensión social, académica y de colaboración del CIAP, integrando funciones de educación ambiental, difusión científica y alojamiento para investigadores.

En esta fase se desarrollan el edificio de educación ambiental, el auditorio, el museo interactivo y las instalaciones de alojamiento, permitiendo ampliar el alcance del centro más allá de la operación técnica y científica.

Desde una perspectiva técnica, esta etapa implica el diseño de espacios de uso público con criterios de accesibilidad universal, seguridad, confort ambiental y flexibilidad de uso, así como la integración de servicios complementarios que permitan la estancia de investigadores y visitantes.

La base conceptual de esta etapa se alinea con tendencias internacionales en centros de investigación, donde la generación de conocimiento se complementa con su difusión y aplicación social. Asimismo, responde a la necesidad de cumplir con criterios de transparencia, participación social y educación ambiental establecidos en marcos regulatorios y políticas públicas.

En la Tabla 5.9, se muestra el resumen de las etapas de desarrollo para el CIAP.

Tabla 5.9 Personal de Soporte o Administrativo.

ETAPA	SUPERFICIE ESTIMADA	OBJETIVO PRINCIPAL	BASE TÉCNICA
Etapa 1	6.3 ha	Habilitación operativa inicial	Infraestructura crítica, continuidad operativa
Etapa 2	1.1 ha	Consolidación científica y ambiental	Especialización, restauración, ampliación analítica
Etapa 3	0.3 ha	Vinculación y expansión funcional	Difusión, colaboración, soporte residencial

Fuente: Elaboración propia, RHG Ingeniería, 2026.

En conjunto, la estrategia de desarrollo por etapas permite que el CIAP evolucione de un núcleo operativo básico a una plataforma integral de investigación, gestión ambiental y vinculación social, garantizando eficiencia en la inversión, reducción de riesgos y adaptación progresiva a las necesidades del proyecto portuario.

Sin embargo, es importante comentar, que, al ser un proyecto prioritario dentro de la ampliación del puerto de Manzanillo en la Laguna de Cuyutlán, el dividirlo en etapas no significa una diferencia entre ellos de años para su implementación, solo es una jerarquización de la importancia de cada estructura y equipamiento del CIAP.

5.6 Criterios Técnicos de Diseño

Los criterios técnicos de diseño del CIAP constituyen el marco rector que orienta la definición arquitectónica, estructural, electromecánica y operativa del conjunto. Estos criterios se fundamentan en la naturaleza del proyecto como infraestructura científica crítica, localizada en un entorno costero con alta exposición ambiental y vinculada a un sistema portuario de alta complejidad.

El enfoque de diseño integra principios de funcionalidad, eficiencia energética, resiliencia, durabilidad, seguridad y cumplimiento normativo, asegurando que el centro pueda operar de manera continua, segura y adaptable a lo largo de su vida útil.

5.6.1 Criterios funcionales

Los criterios funcionales del CIAP se basan en la organización eficiente de flujos de personas, materiales, información y energía, bajo un esquema de segregación operativa que evite interferencias entre actividades incompatibles. La base conceptual de este enfoque proviene de la ingeniería de procesos y del diseño de instalaciones científicas, en donde la zonificación es clave para garantizar seguridad, eficiencia y trazabilidad.

La distribución del conjunto debe establecer claramente tres dominios funcionales: áreas públicas, áreas técnicas y áreas de bioseguridad, cada uno con accesos, circulaciones y controles diferenciados. Esta segregación permite evitar cruces entre visitantes y procesos científicos, reducir riesgos de contaminación cruzada y mejorar la eficiencia operativa.

Asimismo, se deben definir jerarquías de acceso y rutas funcionales que permitan la circulación independiente de personal técnico, visitantes, materiales, residuos y fauna, en su caso. Esto es particularmente relevante en edificios como laboratorios, vivero, unidad de fauna y embarcadero. En la Tabla 5.10 se resumen los principios funcionales y su implicación en el diseño.

Tabla 5.10 Principios Funcionales del CIAP.

CRITERIO FUNCIONAL	BASE TÉCNICA	IMPLICACIÓN DE DISEÑO
Segregación de áreas	Bioseguridad y procesos	Separación física y control de accesos
Flujos diferenciados	Ingeniería de procesos	Circulaciones independientes
Jerarquía de accesos	Seguridad operativa	Control de entradas y salidas
Integración funcional	Eficiencia operativa	Conectividad entre unidades

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.6.2 Criterios climáticos

El diseño del CIAP debe responder a las condiciones climáticas propias de la zona costera de Manzanillo, caracterizadas por alta radiación solar, humedad elevada, presencia de niebla salina y vientos predominantes. La base técnica de estos criterios se encuentra en estrategias de diseño bioclimático y eficiencia energética, que buscan optimizar el comportamiento térmico del edificio y reducir la dependencia de sistemas mecánicos.

La orientación de los edificios debe minimizar la exposición al asoleamiento poniente, que genera mayores cargas térmicas, mientras que la disposición de aberturas y patios debe favorecer la ventilación cruzada. Las cubiertas deben diseñarse con pendientes adecuadas, ventilación y materiales resistentes a la corrosión, mientras que las fachadas deben incorporar elementos de sombreado que reduzcan la ganancia térmica.

En áreas críticas como laboratorios y centros de datos, se deben implementar sistemas de climatización controlada, mientras que en áreas administrativas y de vinculación se debe privilegiar el confort pasivo.

Tabla 5.11 Criterios de Diseño Climático.

VARIABLE CLIMÁTICA	BASE TÉCNICA	ESTRATEGIA DE DISEÑO
Radiación solar	Balance térmico	Orientación y sombreados
Humedad	Confort y durabilidad	Ventilación y materiales resistentes
Viento	Ventilación natural	Aperturas y patios
Salinidad	Corrosión	Selección de materiales

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.6.3 Criterios de resiliencia

La resiliencia del CIAP se define como la capacidad del conjunto para mantener su operación ante condiciones adversas, incluyendo eventos meteorológicos extremos, fallas de servicios y contingencias ambientales. Este criterio es fundamental en infraestructura crítica asociada a sistemas portuarios.

La base técnica de la resiliencia se sustenta en la gestión de riesgos y en el diseño de sistemas redundantes, robustos y adaptables. Esto implica considerar elevación de plataformas respecto a niveles de inundación, diseño de sistemas de drenaje pluvial eficientes, protección de instalaciones críticas y redundancia en sistemas eléctricos y de telecomunicaciones.

Asimismo, se deben incorporar estrategias de diseño que permitan la operación parcial del centro en caso de afectaciones, garantizando la continuidad de funciones críticas como monitoreo, análisis y respuesta a emergencias.

Tabla 5.12 Criterios de Resilencia.

RIESGO	BASE TÉCNICA	ESTRATEGIA DE DISEÑO
Inundación	Hidrología	Elevación de plataformas
Fallas eléctricas	Continuidad operativa	Sistemas de respaldo
Eventos extremos	Gestión de riesgos	Diseño robusto
Interrupción de datos	Infraestructura digital	Redundancia de telecomunicaciones

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.6.4 Criterios normativos

El diseño del CIAP debe cumplir con el marco normativo aplicable en materia de construcción, seguridad, medio ambiente y operación de instalaciones científicas. La base técnica de este cumplimiento se encuentra en la integración de normativas locales, nacionales e internacionales que regulan aspectos estructurales, sanitarios, ambientales y de seguridad.

Esto incluye reglamentos de construcción, normas oficiales mexicanas relacionadas con seguridad e higiene, manejo de sustancias químicas, calidad del agua, accesibilidad universal y protección civil. Asimismo, se deben considerar lineamientos específicos para laboratorios, centros de datos y manejo de residuos peligrosos.

El cumplimiento normativo no sólo garantiza la viabilidad legal del proyecto, sino que establece estándares de seguridad, calidad y operación que deben integrarse desde la etapa de anteproyecto.

Tabla 5.13 Criterios Normativos.

ÁMBITO NORMATIVO	REFERENCIA CONCEPTUAL	IMPLICACIÓN DE DISEÑO
Construcción	Reglamentos locales	Seguridad estructural
Ambiental	Evaluación de impacto	Monitoreo y mitigación
Seguridad	Protección civil	Evacuación y control
Accesibilidad	Diseño universal	Inclusión y uso público

Fuente: Elaboración propia, RHG Ingeniería, 2026.

En conjunto, estos criterios técnicos de diseño permiten establecer una base sólida para el desarrollo del CIAP, asegurando que el conjunto responda de manera integral a las condiciones del sitio, a las exigencias operativas del sistema portuario y a los requerimientos normativos aplicables.

5.7 Criterios de Ingeniería para Anteproyecto

El desarrollo del CIAP debe abordarse, a nivel de anteproyecto, bajo una lógica de infraestructura crítica de soporte científico, operativo y ambiental, emplazada en un entorno lagunar–costero con alta exposición a humedad, salinidad, viento, radiación solar, potencial de inundación y exigencias de continuidad operativa. En este sentido, los criterios de ingeniería no pueden limitarse a una definición arquitectónica de espacios, sino que deben establecer las bases de desempeño estructural, funcional, ambiental, electromecánico y logístico que permitan evolucionar con certeza hacia la ingeniería básica y el proyecto ejecutivo.

La base técnica del anteproyecto parte de cinco condicionantes principales:

1. La primera es la naturaleza del sitio, presumiblemente caracterizado por suelos blandos, estratos saturados, alta compresibilidad y posible presencia de depósitos finos lagunares, lo que obliga a considerar desde esta etapa campañas geotécnicas específicas, análisis de capacidad de carga, asentamientos totales y diferenciales, estabilidad global y evaluación del comportamiento del terreno ante cargas permanentes y variables.

2. La segunda condicionante es la exposición del conjunto a un ambiente marino agresivo, que incrementa los riesgos de corrosión en elementos estructurales, equipos, canalizaciones, fijaciones, envolventes y componentes electromecánicos.

3. La tercera corresponde a la necesidad de continuidad operativa en áreas sensibles, particularmente laboratorios, centro de monitoreo, telecomunicaciones, conservación de muestras y sistemas de control, las cuales no pueden depender de una sola fuente de energía o de una sola ruta de datos.

4. La cuarta deriva del carácter mixto del centro, que combina áreas públicas, técnicas, científicas, de bioseguridad, alojamiento y operación de campo, por lo que el diseño debe separar flujos, jerarquizar accesos y evitar interferencias entre visitantes, personal técnico, materiales, residuos y fauna.

5. La quinta condicionante es el horizonte de crecimiento de veinte años establecido en el programa preliminar, lo que obliga a plantear un esquema modular, ampliable y técnicamente escalable.

Desde el punto de vista estructural, el CIAP debe concebirse con criterios de durabilidad reforzada y confiabilidad funcional. La ingeniería estructural deberá sustentarse en el marco normativo mexicano aplicable en materia de acciones por cargas gravitacionales, viento y, en su caso, sismo, utilizando como referencia las Normas Técnicas Complementarias vigentes, manuales de diseño de la Comisión Federal de Electricidad para estructuras expuestas a viento y criterios de diseño por durabilidad en ambientes agresivos. Dado el contexto costero del Pacífico mexicano, las acciones de viento adquieren especial relevancia no sólo por la posible ocurrencia de ciclones tropicales, sino por los efectos de presión y succión sobre cubiertas ligeras, fachadas ventiladas, marquesinas, elementos exteriores y edificaciones de baja altura con grandes claros, como auditorios, áreas de vivero, cubiertas de maniobra y embarcadero. En esta etapa, el anteproyecto debe prever configuraciones estructurales regulares, con centros de masa y rigidez razonablemente balanceados, evitando voladizos innecesarios, cubiertas excesivamente livianas sin rigidización adecuada y cambios abruptos de rigidez entre módulos.

En función de la agresividad ambiental, la selección del sistema estructural deberá privilegiar soluciones robustas de concreto reforzado con especificaciones de durabilidad aumentada, incluyendo control de relación agua-cemento, recubrimientos mayores al mínimo normativo, empleo de aditivos o cementantes suplementarios cuando el estudio de durabilidad lo justifique y protección de juntas y anclajes expuestos. En elementos metálicos secundarios o de gran claro podrá considerarse acero estructural, siempre que incorpore galvanizado, sistemas multicapa de protección anticorrosiva y un programa de mantenimiento accesible. La decisión entre cimentaciones superficiales mejoradas, losas de cimentación, pilas o pilotes no debe cerrarse en esta fase, pero sí debe quedar condicionada a una investigación geotécnica que incluya sondeos, muestreo inalterado, pruebas de laboratorio y, preferentemente, evaluación del nivel freático, consolidación y agresividad química del suelo. En un conjunto de esta naturaleza, el criterio rector no será únicamente la seguridad última, sino el control de deformaciones y asentamientos diferenciales, especialmente en edificios con equipos de precisión, salas de servidores, laboratorios instrumentales y áreas con conexiones rígidas entre módulos.

La implantación general deberá partir de cotas de desplante seguras respecto a inundación pluvial, niveles extraordinarios de laguna, escurrimientos internos y eventos meteorológicos severos. La referencia técnica para ello deberá provenir del estudio topohidráulico del sitio, de los niveles de aguas máximas extraordinarias y del análisis combinado entre lluvia intensa, marea de tormenta y fallas temporales de drenaje. Por lo tanto, el anteproyecto debe incorporar plataformas elevadas, pendientes controladas, secciones de desalojo pluvial, bordos o taludes estabilizados cuando proceda, así como rutas de acceso que permanezcan operables durante eventos críticos. Este criterio es particularmente importante para el centro de monitoreo, laboratorios, cuarto eléctrico, cuarto de bombas, planta de tratamiento, almacenamiento de

reactivos y centro de datos, ya que una inundación en estas zonas comprometería simultáneamente la operación científica y la seguridad ambiental.

En materia de arquitectura técnica y envolvente, el conjunto debe responder a una estrategia bioclimática compatible con el entorno costero. La base técnica aquí es doble: por un lado, reducir demanda energética y mejorar confort mediante ventilación cruzada, control solar, orientación adecuada y aleros; por otro, garantizar que las áreas que sí requieren ambiente controlado, como laboratorios, cuartos fríos, servidores y salas instrumentales, cuenten con envolventes de mayor hermeticidad y sistemas HVAC específicos. El anteproyecto debe separar con claridad los edificios de funcionamiento predominantemente pasivo, como educación ambiental, oficinas abiertas y algunas áreas de alojamiento, de aquellos que requieren climatización de precisión o extracción especializada. Esta diferenciación evita sobredimensionamientos energéticos y permite una estrategia de operación más eficiente. En consecuencia, las cubiertas deberán diseñarse con pendientes adecuadas, materiales resistentes a atmósfera salina, sistemas de fijación de alta durabilidad y soluciones que reduzcan ganancias térmicas. Las fachadas poniente deberán protegerse con elementos de sombreado, y los acabados expuestos deberán seleccionarse con base en su resistencia a humedad, radiación UV, niebla salina y facilidad de mantenimiento.

El edificio de laboratorios e investigación constituye el núcleo técnico más exigente del CIAP y, por tanto, exige criterios particulares de ingeniería. La base de diseño de este edificio deriva de los requerimientos de seguridad química, trazabilidad analítica, segregación de procesos, bioseguridad operativa y estabilidad ambiental interna. La zonificación interior deberá separar de manera inequívoca la recepción de muestras, el pretratamiento, los laboratorios húmedos, las áreas de análisis instrumental, el almacenamiento de reactivos, el acopio temporal de residuos, la preparación de medios y las áreas de trabajo de investigadores. Esta separación no es sólo arquitectónica; responde a la necesidad de controlar contaminación cruzada, proteger personal y equipos, y sostener cadenas de custodia y calidad analítica. El diseño de instalaciones deberá prever presión diferencial donde proceda, extracción localizada en puntos de emisión, campanas o gabinetes según el tipo de proceso, rutas independientes para efluentes potencialmente contaminados y materiales interiores resistentes a agentes químicos y humedad. En particular, el laboratorio de contaminantes y química analítica, la microbiología y la conservación de muestras demandarán condiciones más estrictas que otras áreas de trabajo seco, por lo que desde el anteproyecto debe definirse una matriz de criticidad operativa que sirva como base para la ingeniería mecánica, eléctrica y sanitaria posterior.

El centro de monitoreo ambiental y datos debe ser tratado como un nodo de misión crítica. Su justificación técnica reside en concentrar datos de sensores remotos, estaciones ambientales, sistemas de telecomunicación, modelación predictiva y gestión de contingencias, por lo que su diseño debe basarse en principios de redundancia, disponibilidad, resiliencia y seguridad física. La sala de monitoreo, el cuarto de servidores, el centro de datos, la sala de crisis y el sistema de respaldo energético no deben entenderse como espacios aislados, sino como una cadena

continua de procesamiento y respuesta. Esto implica establecer desde el anteproyecto una arquitectura funcional con rutas segregadas de energía normal y de emergencia, canalizaciones dedicadas de voz y datos, control térmico estable, filtración de aire, detección y supresión de incendio compatibles con equipo electrónico, y restricción de acceso por niveles. En términos de ingeniería, la configuración recomendable es la de un sistema con respaldo de energía mediante UPS para transición inmediata y planta de emergencia para autonomía operativa, además de una topología de red con redundancia física que minimice la pérdida de servicio ante una falla puntual. El taller de calibración de sensores y el almacén de equipos de monitoreo deben ubicarse funcionalmente asociados a esta unidad para reducir tiempos de mantenimiento y reposición.

En el edificio administrativo y en el edificio de educación ambiental y vinculación, el criterio rector no es la criticidad analítica sino la eficiencia operativa, la claridad de flujos y la flexibilidad de uso. Sin embargo, ambos deben diseñarse con criterios de ingeniería compatibles con el resto del conjunto. El edificio administrativo requiere una infraestructura robusta de voz, datos, respaldo documental, control de accesos y condiciones adecuadas de habitabilidad para jornadas extendidas. La educación ambiental y vinculación, por su parte, integra espacios de concentración pública como vestíbulo, auditorio, museo, aulas y centro de documentación, por lo que debe diseñarse con especial atención a cargas de ocupación, rutas de evacuación, acústica, accesibilidad universal, control térmico y operación segura en eventos. La base técnica de esta unidad está asociada a su función como interfaz entre el centro, las comunidades, el sector educativo, las autoridades y los actores del sistema portuario, lo que la convierte en una pieza estratégica para divulgación, transparencia y socialización de resultados.

El alojamiento para investigadores y técnicos debe entenderse como infraestructura de soporte operativo y no únicamente como componente habitacional. Su función dentro del CIAP está vinculada a campañas intensivas, estancias cortas de especialistas externos, operación nocturna o extendida y atención de emergencias ambientales. Desde el anteproyecto, esto exige diseñar una unidad con estándares de habitabilidad adecuados, independencia razonable respecto de las áreas públicas, cercanía funcional con laboratorios y monitoreo, y servicios complementarios suficientes para asegurar autonomía temporal. La base técnica del alojamiento se relaciona con continuidad de operación, reducción de tiempos de respuesta y capacidad de atraer personal especializado en periodos críticos del proyecto o durante campañas de muestreo de alta intensidad.

La unidad de conservación ecológica y vivero, así como la unidad de rescate y manejo de fauna, deben proyectarse bajo criterios de bioseguridad, sanidad, manejo diferenciado y control ambiental básico. La primera debe sostener procesos de propagación, germinación, rustificación y apoyo botánico orientados a restauración ecológica y compensación ambiental, por lo que su ingeniería debe considerar demanda de agua, calidad de riego, drenajes, ventilación, control térmico parcial, sombreados y durabilidad de estructuras ligeras o semicubiertas. La segunda debe permitir recepción, valoración, cuarentena, recuperación y resguardo temporal de ejemplares, lo que demanda separación sanitaria, materiales lavables, control de olores, facilidad de limpieza,

disposición segura de residuos biológico-infecciosos cuando aplique y circuitos de operación que eviten contacto innecesario entre fauna en observación, personal técnico y visitantes. En ambos casos, el fundamento técnico está dado por la necesidad de cumplir medidas de mitigación, restauración y manejo ambiental derivadas de proyectos de infraestructura con incidencia sobre humedales, aves, reptiles, peces y otras especies asociadas al sistema lagunar.

El taller, almacenes y servicios técnicos, así como el embarcadero y apoyo operativo de campo, constituyen la base logística del centro. Su diseño debe responder a principios de operación segura, mantenimiento preventivo, control de inventarios, preparación de campañas y maniobra eficiente de equipos. El taller mecánico ligero, almacenes, área de carga y descarga y preparación de campañas deben resolver circulaciones de vehículos utilitarios, acceso de materiales, limpieza de equipos y segregación entre herramientas, refacciones, consumibles, combustibles y materiales sensibles. En el caso del embarcadero, la base técnica incluye la necesidad de compatibilizar el nivel de agua, las fluctuaciones locales, la maniobrabilidad de embarcaciones menores, la seguridad del personal, el almacenamiento de equipo náutico y la preparación de salidas de campo. A nivel de anteproyecto, es indispensable prever un muelle o plataforma de atraque con especificaciones congruentes con el calado y tipo de embarcaciones de trabajo, una rampa de botado menor y un patio de maniobras que permita operaciones sin interferir con áreas públicas.

En cuanto a instalaciones eléctricas, el CIAP debe diseñarse con una jerarquización clara de cargas normales, esenciales y críticas. La base técnica para ello es la continuidad diferenciada requerida por cada edificio. Mientras que oficinas, aulas o áreas museográficas pueden tolerar interrupciones breves, los laboratorios con equipos sensibles, los cuartos fríos, los servidores, la sala de monitoreo y algunos sistemas de seguridad requieren continuidad inmediata o restablecimiento prioritario. Por ello, el anteproyecto debe prever una subestación o acometida con capacidad de crecimiento, tableros seccionados, canalizaciones registrables, protecciones coordinadas y al menos dos niveles de respaldo: UPS para cargas que no admiten interrupción y planta de emergencia para autonomía operativa durante fallas prolongadas. El cuarto de baterías, la subestación, los tableros principales y las rutas de distribución deberán ubicarse fuera de zonas de riesgo de inundación, con ventilación, accesibilidad para mantenimiento y protección anticorrosiva. Adicionalmente, deben incorporarse desde esta etapa los criterios de sistema de puesta a tierra, protección contra descargas atmosféricas y supresión de sobretensiones, dada la sensibilidad del equipamiento electrónico y analítico.

Las instalaciones hidráulicas, sanitarias y de manejo de efluentes requieren un tratamiento particularmente cuidadoso por la coexistencia de usos domésticos, técnicos, de riego, limpieza, laboratorio y posible atención a fauna. La base técnica del diseño debe separar claramente la red de agua potable, la red de agua tratada o de reúso cuando sea viable, la red sanitaria, la red pluvial y las descargas especiales. La planta de tratamiento considerada dentro de las obras complementarias adquiere relevancia no sólo para cumplir criterios ambientales, sino para habilitar el reúso de agua en vivero, lavado de áreas exteriores y servicios auxiliares, reduciendo

presiones sobre el abastecimiento. En paralelo, los laboratorios no deben descargar de manera directa sin pretratamiento cuando manejen reactivos, medios o soluciones contaminantes; por tanto, el anteproyecto debe prever tanques de neutralización, segregación de corrientes o sistemas de manejo especial en función del catálogo analítico definitivo. El drenaje pluvial debe diseñarse con criterios de tormenta severa y rápida evacuación superficial, evitando anegamientos en patios técnicos, accesos, áreas de almacenamiento y cuartos de instalaciones.

Las telecomunicaciones y sistemas de datos deben proyectarse como infraestructura troncal del conjunto. La base técnica es que el CIAP no sólo produce análisis en laboratorio, sino que integra datos en tiempo real, imágenes, teledetección, modelación ambiental y coordinación operativa. En consecuencia, el anteproyecto debe incluir una red troncal preferentemente basada en fibra óptica, cuartos de telecomunicaciones por edificio, trayectorias protegidas, rutas redundantes entre edificios estratégicos y capacidad de crecimiento para sensores, estaciones remotas, videovigilancia, control de accesos, automatización y transmisión de grandes volúmenes de datos. El centro de monitoreo y el edificio de laboratorios deberán vincularse mediante una arquitectura digital robusta que permita interoperabilidad entre bases de datos, instrumentos, plataformas SIG y sistemas de visualización. A ello debe sumarse una política de seguridad física y lógica, con control por perfiles de acceso y resguardo redundante de información crítica.

En materia de seguridad, el anteproyecto debe desarrollar una estrategia integral que abarque seguridad humana, protección patrimonial, seguridad química, seguridad biológica y respuesta a emergencias. La base técnica para ello es la coexistencia de visitantes, personal administrativo, investigadores, técnicos, fauna en manejo, reactivos, equipos delicados y operación náutica. Las rutas de evacuación, salidas de emergencia, puntos de reunión, compartimentación, detección y supresión de incendio, control de accesos y manejo de residuos deben quedar definidos en el esquema funcional desde esta etapa, aunque su cálculo detallado se refine posteriormente. Es especialmente importante que el edificio de laboratorios, el almacén temporal de residuos, la unidad de fauna, el centro de datos y el embarcadero dispongan de protocolos espaciales diferenciados y barreras de seguridad acordes con sus riesgos específicos. En el mismo sentido, la accesibilidad universal no debe tratarse como una adición posterior, sino como un criterio rector de diseño para circulaciones, sanitarios, espacios de atención pública, aulas, auditorio, alojamiento y accesos principales.

La lógica de desarrollo por etapas constituye otro fundamento técnico central del anteproyecto. La etapa 1, integrada por el núcleo operativo inicial, debe asegurar autosuficiencia funcional mínima mediante la puesta en operación del edificio administrativo, laboratorios básicos, centro de monitoreo, taller, embarcadero e infraestructura primaria. La etapa 2 debe ampliar capacidad científica y ambiental con la consolidación de laboratorios, vivero, rescate de fauna y plataforma de datos avanzada. Finalmente, la etapa 3 debe fortalecer la dimensión pública e interinstitucional mediante educación ambiental, auditorio, museo interactivo y alojamiento. Esta secuencia no es solamente financiera o constructiva; responde a una estrategia de maduración funcional en la que primero se habilita la capacidad de medir, operar y responder,

después se amplía la capacidad de restaurar y especializar, y finalmente se consolida la capacidad de formar, comunicar y alojar colaboradores.

Para fines de control del anteproyecto, resulta útil sintetizar las bases de ingeniería por componente crítico en la Tabla 5.14.

Tabla 5.14 Criterios Normativos.

COMPONENTE	BASE TÉCNICA DOMINANTE	VARIABLE DE DISEÑO PRINCIPAL	IMPLICACIÓN DE ANTEPROYECTO
Cimentaciones y plataforma	Suelos blandos lagunares, nivel freático, riesgo de asentamientos	Capacidad de carga, consolidación, cota de desplante	Requiere campaña geotécnica y definición preliminar de sistema de cimentación
Estructura	Ambiente costero agresivo y acciones de viento	Durabilidad, rigidez, estabilidad global	Favorece concreto reforzado durable y acero protegido en elementos selectivos
Envolvente	Radiación, humedad, salinidad y ventilación	Ganancia térmica, corrosión, mantenimiento	Exige protecciones solares, materiales resistentes y diferenciación entre edificios pasivos y controlados
Laboratorios	Seguridad química, bioseguridad, trazabilidad	Segregación, presión, extracción, materiales	Obliga a zonificación estricta y definición de áreas críticas para HVAC y sanitarias
Monitoreo y datos	Continuidad operativa y misión crítica	Redundancia eléctrica y digital	Requiere UPS, planta, control ambiental y rutas redundantes de telecomunicaciones
Hidrosanitario	Convivencia de usos domésticos, técnicos y de riego	Separación de redes, tratamiento y reúso	Demanda planta de tratamiento, drenajes segregados y manejo especial de efluentes
Operación de campo	Acceso seguro a la laguna y logística de campañas	Maniobra, almacenamiento y seguridad náutica	Requiere muelle funcional, patio de maniobras y soporte técnico asociado
Conservación y fauna	Restauración y manejo ambiental	Sanidad, agua, ventilación y segregación	Exige bioseguridad, facilidad de limpieza y áreas exteriores especializadas
Desarrollo futuro	Crecimiento a 25 años	Modularidad y reserva de expansión	Condiciona redes maestras, vialidades y capacidad instalada inicial escalable

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Desde una perspectiva de factibilidad técnica, el escenario base de 6.3 ha construido resulta el punto de equilibrio más adecuado entre capacidad operativa, especialización funcional y posibilidad de crecimiento, ya que permite integrar laboratorios, monitoreo, conservación, logística, educación y alojamiento sin comprometer la separación de flujos ni la escalabilidad

futura. El escenario compacto tendería a tensionar la coexistencia de funciones críticas, mientras que el expandido exigiría una carga de inversión y operación superior desde etapas tempranas, sin que necesariamente se justifique antes de consolidar la demanda científica y operativa. Esta lectura coincide con la cifra de control sugerida en el programa preliminar.

En síntesis, el anteproyecto del CIAP debe entenderse como el paso en que se fijan las decisiones de ingeniería que determinarán la viabilidad del centro durante su vida útil. No se trata solamente de asignar superficies, sino de establecer las bases técnicas que hagan compatible un conjunto científico-portuario con un ambiente costero exigente, con requerimientos de continuidad operativa, con obligaciones de desempeño ambiental y con capacidad de crecimiento modular.

5.8 Matriz de Criticidad Operativa e Interdependencias

La transformación de la matriz área–función hacia una matriz de criticidad[2] operativa permite clasificar cada unidad del CIAP en función de su impacto sobre la continuidad del sistema, el riesgo asociado a su interrupción y los requerimientos técnicos necesarios para sostener su operación. Este enfoque se fundamenta en criterios de ingeniería de confiabilidad (reliability engineering), análisis de criticidad (RCA/FMEA)[3] y diseño de infraestructura crítica, donde se priorizan redundancias, niveles de servicio y estrategias de recuperación.

5.8.1 Matriz de criticidad operativa

La criticidad se clasifica en tres niveles: alta, media y baja. La clasificación considera la consecuencia de falla, el tiempo máximo de interrupción permisible (MTTR[4] objetivo), la necesidad de operación continua y la dependencia sistémica con otras áreas.

---

[2] La criticidad es el nivel de importancia, riesgo o impacto que tiene un componente, sistema o proceso dentro de un conjunto mayor. Se utiliza principalmente para priorizar recursos (como mantenimiento preventivo) basándose en las consecuencias de una falla en seguridad, producción o costos

[3] El análisis de criticidad (RCA/FMEA) combina herramientas de gestión de riesgos para optimizar la confiabilidad. FMEA (AMFE) es proactivo, identificando fallas potenciales antes de que ocurran. RCA (ACR) es reactivo, investigando las causas raíz de problemas tras su ocurrencia. Juntos mejoran la seguridad y reducen costos

a. FMEA/AMFE (Análisis de Modos y Efectos de Fallas): Es un enfoque estructurado y proactivo diseñado para identificar cómo un proceso o producto puede fallar.
b. RCA/ACR? (Análisis de Causa Raíz): Es un proceso reactivo utilizado para investigar las causas fundamentales de un problema, incidente o error después de que este ha ocurrido.
c. Enfoque: FMEA es proactivo (antes de), RCA es reactivo (después de).
d. Conexión: El FMEA ayuda a priorizar en qué sistemas enfocar el RCA.
e. Beneficios Comunes: Ambos son esenciales para una gestión de confiabilidad de alto desempeño, optimizando el mantenimiento y reduciendo el riesgo operacional.

[4] Mean Time To Repair (Tiempo Medio de Reparación o Tiempo Medio de Recuperación). Es un indicador clave de mantenimiento que mide el tiempo promedio necesario para diagnosticar, reparar y volver a poner en funcionamiento un equipo, sistema o componente tras un fallo inesperado

Tabla 5.15 Matriz de Criticidad Operativa.

ÁREA	NIVEL DE CRITICIDAD	CONSECUENCIA DE FALLA	REQUERIMIENTOS TÉCNICOS CLAVE	NIVEL DE SERVICIO ESPERADO
Laboratorios	Alta	Pérdida de datos, invalidación de muestras, incumplimiento normativo	HVAC controlado, energía ininterrumpida (UPS), manejo de residuos, control de accesos	Operación continua / tolerancia a falla mínima
Monitoreo y datos	Alta	Pérdida de visibilidad en tiempo real, retraso en decisiones, riesgo operativo	Redundancia eléctrica (UPS + planta), climatización de precisión, telecom redundante	24/7 con alta disponibilidad (>99.5%)
Embarcadero	Alta	Imposibilidad de monitoreo en campo, retraso en respuesta a eventos	Acceso seguro, operación náutica continua, soporte logístico	Disponibilidad operativa permanente
Obras complementarias (eléctrico/hidráulico)	Alta	Paro total o parcial del centro	Redundancia, mantenimiento preventivo, protección contra inundación	Continuidad con respaldo
Talleres y almacenes	Media	Retrasos en mantenimiento, degradación de equipos	Inventarios, herramientas, accesibilidad logística	Alta disponibilidad operativa
Vivero	Media	Afectación en programas de restauración	Sistemas de riego, control ambiental básico	Operación continua no crítica
Rescate de fauna	Media	Riesgo a fauna, incumplimiento ambiental	Bioseguridad, control sanitario	Operación continua condicionada
Administrativo	Media	Retrasos en gestión y toma de decisiones	Sistemas de información, conectividad	Operación en horario extendido
Educación ambiental	Baja	Impacto social y de vinculación	Seguridad, accesibilidad	Operación programada
Alojamiento	Baja	Afectación logística, no crítica	Servicios básicos, habitabilidad	Operación intermitente

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Desde el punto de vista técnico, las áreas clasificadas como críticas altas requieren diseño con redundancia (N+1), protección contra fallas, prioridad en restablecimiento y ubicación fuera de zonas de riesgo. Las áreas de criticidad media requieren confiabilidad operativa, mientras que las de baja criticidad pueden operar bajo esquemas convencionales.

Tabla 5.16 Implicaciones de Diseño Derivadas de la Criticidad.

NIVEL DE CRITICIDAD	ESTRATEGIA DE DISEÑO	EJEMPLO APLICADO EN CIAP
Alta	Redundancia, respaldo, aislamiento, monitoreo continuo	UPS en monitoreo, control ambiental en laboratorios
Media	Mantenimiento preventivo, accesibilidad, flexibilidad	Talleres, vivero
Baja	Diseño convencional con cumplimiento normativo	Educación, alojamiento

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.8.2 Matriz de interdependencias entre áreas.

La matriz de interdependencias permite identificar cómo fluye la información, los materiales y la operación dentro del CIAP, estableciendo relaciones de dependencia directa entre áreas. Este análisis se fundamenta en principios de ingeniería de sistemas y diseño de procesos, donde cada unidad se entiende como parte de una cadena funcional.

El análisis de interdependencias evidencia que el CIAP opera como un sistema cerrado de generación y uso de información. El flujo principal inicia en el embarcadero y el monitoreo de campo, se consolida en los laboratorios, se integra en el centro de datos y se transforma en decisiones a nivel administrativo. Posteriormente, esta información se traduce en acciones de restauración, operación portuaria o comunicación social.

Desde la perspectiva de diseño, esto implica que las áreas con mayor número de dependencias deben ubicarse estratégicamente, con conectividad directa y prioritaria, minimizando tiempos de traslado y pérdidas de información. Asimismo, las áreas de soporte (talleres y obras complementarias) deben tener acceso universal y capacidad de intervención rápida.

Este enfoque permite validar que el CIAP no es una suma de edificios, sino un sistema integrado en el que la eficiencia depende de la correcta articulación entre sus componentes.

Tabla 5.17 Matriz de Interdependencias entre Áreas.

ÁREA ORIGEN	ÁREA DEPENDIENTE	TIPO DE DEPENDENCIA	DESCRIPCIÓN TÉCNICA
Embarcadero	Laboratorios	Datos/muestras	Provee muestras físicas y datos de campo
Embarcadero	Monitoreo	Datos	Alimenta sensores y observaciones en tiempo real
Monitoreo	Dirección / Administrativo	Información	Proporciona información para toma de decisiones
Laboratorios	Monitoreo	Validación	Retroalimentación para calibración de modelos
Laboratorios	Dirección	Resultados	Soporte técnico para decisiones estratégicas
Vivero	Laboratorios	Información	Validación de condiciones ambientales
Rescate fauna	Laboratorios	Diagnóstico	Análisis sanitario y biológico
Talleres	Todas las áreas	Soporte	Mantenimiento y operación de equipos
Obras complementarias	Todas las áreas	Infraestructura	Suministro de energía, agua y servicios
Educación	Dirección	Comunicación	Difusión y retroalimentación social
Alojamiento	Todas (indirecto)	Soporte humano	Facilita operación continua

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.9 Diagrama de Flujo Operativo del CIAP

El diagrama de flujo operativo del CIAP permite representar, en términos funcionales, la secuencia principal de procesos mediante la cual el centro transforma observaciones de campo, muestras, datos instrumentales y requerimientos operativos en información técnica validada, decisiones de gestión y acciones de respuesta ambiental o portuaria. Aunque no se trata de un diagrama de proceso industrial en sentido estricto, su construcción sigue la lógica de un Process Flow Diagram (PFD)[5], en el que se identifican entradas, nodos de transformación, rutas de retroalimentación y salidas operativas.

[5] Un Diagrama de Flujo de Proceso (PFD, por sus siglas en inglés) es una representación gráfica simplificada que muestra el flujo de materiales, energía y los equipos principales. Se utiliza en ingeniería para visualizar la estructura general, las operaciones unitarias y las condiciones operativas clave de manera esquemática.

La base conceptual de este flujo reside en la integración de tres cadenas principales. La primera corresponde a la cadena de adquisición de información, que inicia en el sistema lagunar, el frente portuario y las estaciones de monitoreo. La segunda corresponde a la cadena de procesamiento y validación, donde intervienen laboratorios, análisis de datos, modelación e interpretación técnica. La tercera corresponde a la cadena de decisión y respuesta, en la que la información validada se traduce en acciones de operación portuaria, gestión ambiental, restauración, contingencia o comunicación institucional.

Desde el punto de vista de diseño, este diagrama permite identificar nodos críticos, puntos de transferencia, dependencias funcionales y necesidades de conectividad física y digital. También sirve como base para establecer relaciones espaciales entre edificios, tiempos máximos de transferencia, requerimientos de respaldo y prioridades de continuidad operativa.

En la Tabla 5.18 se presenta la representación funcional del flujo principal del CIAP. Este flujo principal incluye además rutas de retroalimentación que son esenciales para el funcionamiento del CIAP. Los resultados de laboratorio alimentan la calibración de modelos y la validación de sensores. La información derivada del monitoreo en tiempo real puede detonar campañas extraordinarias de muestreo o activar protocolos de contingencia. Las acciones de restauración o rescate de fauna generan a su vez nuevos datos que regresan al sistema analítico para evaluar efectividad.

Finalmente, la información difundida mediante vinculación y cumplimiento normativo produce requerimientos institucionales que retroalimentan prioridades de monitoreo y líneas de investigación.

Para fines de anteproyecto, resulta útil representar también el flujo por subsistemas operativos, ver Tabla 5.19. Bajo un enfoque de ingeniería de procesos, el flujo operativo del CIAP evidencia que los nodos de mayor criticidad funcional son el embarcadero y la adquisición de datos, los laboratorios, el centro de monitoreo y la dirección técnica, ya que en ellos se concentran las transiciones que convierten observaciones dispersas en decisiones ejecutables. Por ello, estos nodos deben contar con rutas cortas de comunicación, redundancia de servicios y protocolos normalizados de transferencia de información.

5.10 Análisis de Modos de Falla (FMEA) por Área Crítica

El análisis de modos y efectos de falla, o FMEA por sus siglas en inglés, constituye una herramienta sistemática para identificar fallas potenciales, evaluar sus efectos sobre el sistema y establecer controles o acciones de mitigación desde el diseño. En el caso del CIAP, esta metodología es especialmente útil porque el centro integra infraestructura crítica, procesos analíticos sensibles, operación de campo, sistemas de telecomunicación y componentes de restauración ambiental, todos ellos con distintos niveles de vulnerabilidad e impacto.

Tabla 5.18 Matriz de Interdependencias entre Áreas.

ETAPA DE PROCESO	ENTRADA PRINCIPAL	UNIDAD RESPONSABLE	TRANSFORMACIÓN / PROCESO	SALIDA PRINCIPAL
Captación en sitio	Variables lagunares, costeras y portuarias	Embarcadero y monitoreo de campo	Muestreo, observación, levantamiento y registro	Muestras, lecturas y datos primarios
Recepción técnica	Muestras y datos de campo	Laboratorios / centro de monitoreo	Clasificación, resguardo, validación inicial y trazabilidad	Muestras registradas y datos estructurados
Análisis especializado	Muestras físicas y digitales	Laboratorios e investigación	Ensayos fisicoquímicos, microbiológicos, biológicos, sedimentológicos y geoambientales	Resultados analíticos y parámetros validados
Integración de información	Resultados + telemetría + series históricas	Centro de monitoreo ambiental y datos	Correlación, depuración, análisis estadístico y modelación	Información técnica integrada
Evaluación y decisión	Información integrada	Dirección técnica / administración	Priorización, interpretación operativa y definición de acciones	Instrucciones operativas, reportes, alertas
Respuesta / intervención	Decisiones técnicas	Operación de campo, vivero, fauna, infraestructura	Atención a eventos, restauración, mantenimiento, mitigación	Acciones correctivas y preventivas
Comunicación y vinculación	Resultados y acciones ejecutadas	Educación ambiental y vinculación	Difusión, capacitación, reporte institucional	Retroalimentación social e institucional

Nota: La lectura secuencial del proceso puede resumirse como sigue: Sistema lagunar y portuario → monitoreo de campo / embarcadero → recepción y trazabilidad → laboratorios y análisis especializado → integración y modelación de datos → evaluación técnica y toma de decisiones → respuesta operativa / restauración / contingencia → comunicación y vinculación
Fuente: Elaboración propia, RHG Ingeniería, 2026.

Tabla 5.19 Matriz de Flujo Operativo.

SUBSISTEMA	NODO DE ENTRADA	NODO DE PROCESO	NODO DE SALIDA	INTERDEPENDENCIA PRINCIPAL
Monitoreo ambiental	Campo / sensores	Centro de monitoreo	Alertas, telemetría, series	Laboratorios y dirección
Analítica ambiental	Recepción de muestras	Laboratorios	Resultados validados	Monitoreo, fauna, vivero
Gestión operativa	Resultados técnicos	Dirección y administración	Decisiones y programación	Todas las áreas
Intervención ecológica	Diagnóstico técnico	Vivero / fauna / campo	Medidas de restauración	Laboratorios y monitoreo
Vinculación institucional	Información validada	Educación y difusión	Informes, capacitación, socialización	Dirección

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Para este anteproyecto, el FMEA se concentra en las áreas de mayor criticidad operativa: laboratorios e investigación, centro de monitoreo ambiental y datos, embarcadero y apoyo operativo, obras complementarias de infraestructura crítica y, de manera complementaria, talleres y almacenes. La evaluación se estructura a partir de cinco variables: el modo de falla, la causa probable, el efecto sobre la operación, los controles actuales o previstos y la acción de diseño recomendada. Cuando resulta pertinente, también se incorpora una apreciación cualitativa de severidad, ocurrencia y detectabilidad para orientar prioridades.

Tabla 5.20 Criterios de Evaluación del FMEA.

VARIABLE	DEFINICIÓN APLICADA AL CIAP
Modo de falla	Forma específica en que un sistema, equipo o proceso puede fallar.
Causa probable	Condición técnica, operativa o ambiental que origina la falla.
Efecto	Consecuencia directa sobre seguridad, continuidad, calidad o cumplimiento.
Severidad	Magnitud del impacto sobre la operación del centro.
Ocurrencia	Probabilidad relativa de que la falla suceda.
Detectabilidad	Facilidad para detectar la falla antes de que produzca efectos mayores.
Acción recomendada	Medida de diseño, operación o mantenimiento para reducir el riesgo.

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.10.1 FMEA de los Laboratorios

El edificio de laboratorios presenta alta criticidad debido a que concentra procesos analíticos cuya interrupción puede provocar pérdida de muestras, invalidación de resultados, incumplimiento normativo o afectación al personal. Los modos de falla más relevantes se presentan en la siguiente Tabla 5.21.

Desde el punto de vista técnico, este análisis confirma que el diseño del edificio debe priorizar continuidad eléctrica, control ambiental, trazabilidad de procesos, segregación de flujos y durabilidad de instalaciones frente al ambiente marino.

Tabla 5.21 Criterios de Evaluación del FMEA de los Laboratorios.

MODO DE FALLA	CAUSA PROBABLE	EFECTO PRINCIPAL	SEVERIDAD	OCURRENCIA	DETECTABILIDAD	ACCIÓN RECOMENDADA
Pérdida de energía en áreas analíticas	Falla de suministro o tableros	Interrupción de equipos, pérdida de conservación de muestras	Alta	Media	Alta	UPS en cargas críticas, planta de emergencia y seccionamiento eléctrico
Falla de HVAC o extracción localizada	Deficiencia mecánica, corrosión, mala operación	Riesgo al personal, contaminación cruzada, descontrol ambiental	Alta	Media	Media	Redundancia parcial, sensores, mantenimiento preventivo y materiales anticorrosivos
Contaminación cruzada de muestras	Deficiente segregación, flujo inadecuado	Invalidación analítica, pérdida de trazabilidad	Alta	Media	Media	Zonificación estricta, protocolos BPL, circulación separada y superficies adecuadas
Manejo inadecuado de residuos	Diseño insuficiente o error operativo	Riesgo sanitario, incumplimiento normativo	Alta	Baja	Media	Cuarto temporal especializado, rutas separadas y procedimiento de gestión integral
Falla en cuarto frío / conservación	Pérdida térmica, falla de equipo	Deterioro de muestras y repetición de campañas	Alta	Media	Alta	Monitoreo de temperatura, alarmas, respaldo energético y equipos redundan

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.10.2 FMEA del centro de monitoreo ambiental y datos

El centro de monitoreo y datos es un nodo de misión crítica cuya falla compromete la visibilidad operativa del sistema lagunar y la capacidad de respuesta ante eventos. Su FMEA se resume a continuación en la Tabla 5.22.

Tabla 5.22 Criterios de Evaluación del FMEA del Centro de Monitoreo Ambiental y Datos.

MODO DE FALLA	CAUSA PROBABLE	EFECTO PRINCIPAL	SEVERIDAD	OCURRENCIA	DETECTABILIDAD	ACCIÓN RECOMENDADA
Caída del sistema de telecomunicaciones	Falla de red, daño físico, humedad	Pérdida de telemetría y comunicación	Alta	Media	Alta	Redundancia de enlaces, rutas protegidas y monitoreo continuo
Falla del centro de datos / servidores	Sobrecalentamiento, energía inestable, hardware	Pérdida temporal de información o capacidad de análisis	Alta	Media	Alta	Climatización de precisión, respaldo, replicación y UPS
Falla de suministro eléctrico continuo	Corte de red o planta	Interrupción de monitoreo 24/7	Alta	Media	Alta	Esquema UPS + planta + transferencia automática
Acceso no autorizado o incidente cibernético	Seguridad insuficiente	Manipulación o pérdida de información	Alta	Baja	Media	Control de acceso físico, perfiles de usuario, segmentación y respaldo seguro
Saturación del sistema ante contingencia	Incremento súbito de datos o eventos	Retraso en análisis y respuesta	Media	Media	Media	

Fuente: Elaboración propia, RHG Ingeniería, 2026.

La interpretación del análisis muestra que la arquitectura de datos del CIAP debe tratarse con criterios equivalentes a los de una instalación crítica, donde redundancia, ciberseguridad, control térmico y respaldo de energía son elementos de diseño indispensables.

5.10.3 FMEA del embarcadero y apoyo operativo de campo

El embarcadero constituye la puerta de enlace entre el centro y el sistema lagunar. Cualquier falla en esta unidad limita de manera inmediata la capacidad de muestreo, verificación en sitio y respuesta a contingencias, ver Tabla 5.23.

5.10.4 FMEA de obras complementarias e infraestructura crítica

Las obras complementarias concentran sistemas eléctricos, hidráulicos, de tratamiento, bombeo y manejo de residuos, cuya falla puede provocar la detención parcial o total del centro, ver Tabla 5.24.

Tabla 5.23 Criterios de Evaluación del FMEA del Embarcadero y Apoyo Operativo de Campo.

MODO DE FALLA	CAUSA PROBABLE	EFECTO PRINCIPAL	SEVERIDAD	OCURRENCIA	DETECTABILIDAD	ACCIÓN RECOMENDADA
Inoperabilidad del muelle o rampa	Daño estructural, variación hidráulica, falta de mantenimiento	Suspensión de salidas de campo	Alta	Media	Alta	Diseño robusto, inspección periódica y ajuste a niveles operativos
Falla de embarcaciones o motores	Mantenimiento deficiente, corrosión	Retraso en campañas y contingencias	Alta	Media	Alta	Programa preventivo, resguardo adecuado y stock de refacciones críticas
Accidente en maniobra o embarque	Deficiente señalización o seguridad	Riesgo al personal y paro temporal	Alta	Baja	Alta	Protocolos náuticos, equipo de seguridad, control de accesos y capacitación
Pérdida o deterioro de equipo de campo	Almacenamiento deficiente, humedad salina	Disminución de calidad de muestreo	Media	Media	Alta	Bodega especializada, control de inventarios y resguardo anticorrosivo
Interrupción logística por clima extremo	Oleaje, viento, lluvia intensa	Imposibilidad de operación en campo	Media	Media	Alta	Procedimientos de cierre, ventanas operativas y capacidades alternas de monitoreo

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Tabla 5.24 Criterios de Evaluación del FMEA de Obras Complementarias e Infraestructura Crítica.

MODO DE FALLA	CAUSA PROBABLE	EFECTO PRINCIPAL	SEVERIDAD	OCURRENCIA	DETECTABILIDAD	ACCIÓN RECOMENDADA
Falla de subestación o tableros principales	Sobrecarga, humedad, corrosión	Paro general o parcial del centro	Alta	Media	Media	Diseño con reserva, compartimentación, protección anticorrosiva y mantenimiento
Falla en planta de tratamiento	Mal dimensionamiento o mantenimiento insuficiente	Incumplimiento ambiental y afectación operativa	Alta	Baja	Media	Redundancia operativa, monitoreo de parámetros y acceso para mantenimiento
Falla en sistema de bombeo / cisterna	Pérdida de presión, daño mecánico	Interrupción de servicios hidráulicos y contra incendio	Alta	Media	Alta	Equipos redundantes, sensores y pruebas periódicas
Inundación de cuartos técnicos	Drenaje insuficiente o cotas inadecuadas	Daño a infraestructura crítica	Alta	Baja	Alta	Sobreelevación, drenaje perimetral y barreras de protección
Manejo deficiente de residuos especiales	Diseño inadecuado o falta de control	Riesgo sanitario y regulatorio	Alta	Baja	Media	Cuartos especializados, segregación y protección

Fuente: Elaboración propia, RHG Ingeniería, 2026.

5.10.5 FMEA de talleres y almacenes

Aunque su criticidad es media, los talleres y almacenes son esenciales para sostener la confiabilidad general del CIAP. Una falla en esta unidad no siempre detiene de inmediato la operación, pero incrementa la probabilidad de fallas acumuladas en otras áreas, ver Tabla 5.25.

5.10.6 Síntesis de prioridades del FMEA

El FMEA realizado evidencia que las prioridades de diseño del CIAP deben centrarse en cinco líneas de acción. La primera es la continuidad eléctrica y digital para laboratorios y monitoreo. La segunda es la protección ambiental y sanitaria en procesos analíticos y de manejo de residuos. La tercera es la confiabilidad logística y náutica del embarcadero. La cuarta es la protección física de cuartos técnicos y sistemas de soporte frente a inundación, corrosión y fallas mecánicas. La quinta es la implantación de una estrategia de mantenimiento preventivo basada en criticidad.

Tabla 5.25 Criterios de Evaluación del FMEA de Talleres y Almacenes.

MODO DE FALLA	CAUSA PROBABLE	EFECTO PRINCIPAL	SEVERIDAD	OCURRENCIA	DETECTABILIDAD	ACCIÓN RECOMENDADA
Desabasto de refacciones o consumibles	Inventario deficiente	Paros prolongados en mantenimiento	Media	Media	Alta	Sistema de inventario mínimo y clasificación ABC de refacciones
Organización inadecuada del almacén	Falta de control logístico	Pérdida de tiempo y errores operativos	Media	Media	Alta	Layout de almacén, trazabilidad y codificación
Falla de equipo de mantenimiento	Uso intensivo o mala conservación	Retraso en reparación de activos críticos	Media	Media	Alta	Mantenimiento preventivo y reposición programada

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Para sintetizar estas prioridades se presenta la Tabla 5.26.

Tabla 5.26 Síntesis de Prioridades del FMEA.

ÁREA CRÍTICA	RIESGO DOMINANTE	ESTRATEGIA DE MITIGACIÓN DE DISEÑO
Laboratorios	Pérdida de control analítico y ambiental	Redundancia eléctrica, HVAC especializado, segregación de procesos
Monitoreo y datos	Interrupción de información en tiempo real	UPS, planta, telecom redundante, ciberseguridad
Embarcadero	Pérdida de capacidad de campo	Diseño náutico robusto, mantenimiento y logística de respaldo
Obras complementarias	Paro sistémico del centro	Protección de infraestructura crítica, equipos redundantes
Talleres y almacenes	Incremento de fallas secundarias	Gestión de activos, inventarios y mantenimiento preventivo

Fuente: Elaboración propia, RHG Ingeniería, 2026.

En términos de anteproyecto, este FMEA no sustituye un análisis detallado por sistemas, pero sí establece con claridad las decisiones de diseño que deben quedar fijadas desde etapas tempranas para garantizar seguridad, continuidad operativa y cumplimiento ambiental.

5.11 Matriz de Requerimientos de Diseño por Edificio

La matriz de requerimientos de diseño por edificio, ver Tabla 5.27, tiene como finalidad traducir el programa arquitectónico y funcional del CIAP en parámetros técnicos verificables para el desarrollo de la ingeniería básica. A diferencia de una relación meramente programática de espacios, esta matriz vincula cada unidad edilicia con sus necesidades específicas de energía, agua, climatización, telecomunicaciones, seguridad, operación y mantenimiento, permitiendo establecer criterios de dimensionamiento preliminar y prioridades de diseño.

Desde el punto de vista metodológico, esta matriz se fundamenta en principios de programación técnica de instalaciones, diseño basado en desempeño, ingeniería de confiabilidad y coordinación interdisciplinaria. Su utilidad radica en que permite identificar qué edificios requieren continuidad operativa reforzada, qué áreas demandan control ambiental especializado, cuáles necesitan redes hidráulicas diferenciadas y cuáles pueden resolverse con esquemas más convencionales. Asimismo, facilita la definición de jerarquías para infraestructura crítica, reserva de capacidad, rutas de servicio y compatibilidad entre sistemas.

En el caso del CIAP, la matriz se vuelve especialmente relevante porque el conjunto combina edificios de naturaleza muy distinta. Algunos, como laboratorios y monitoreo, operan con criterios de alta criticidad y requieren instalaciones complejas; otros, como educación ambiental y alojamiento, responden a lógicas de confort, ocupación pública y habitabilidad; mientras que unidades como el embarcadero, vivero y talleres presentan requerimientos predominantemente logísticos, operativos y de robustez frente al ambiente costero. Por ello, la matriz no debe leerse sólo como una lista de necesidades, sino como una herramienta de integración entre arquitectura, estructura, ingeniería electromecánica, telecomunicaciones y operación.

La estructura de requerimientos se organiza en ocho categorías técnicas: criticidad operativa, requerimientos eléctricos, requerimientos hidráulicos y sanitarios, climatización y ventilación, telecomunicaciones y datos, seguridad y control, condicionantes constructivas, y observaciones de operación y mantenimiento. Estas categorías permiten resumir de manera clara la lógica de diseño de cada edificio.

La matriz anterior confirma que el diseño del CIAP debe apoyarse en una jerarquización clara de edificios según criticidad y tipo de requerimiento. Los edificios de laboratorios, monitoreo, embarcadero y obras complementarias conforman el núcleo de infraestructura crítica del conjunto. En ellos, los sistemas eléctricos, de datos y de soporte técnico deben diseñarse con criterios de continuidad, redundancia y tolerancia reducida a fallas. En contraste, el edificio administrativo, los talleres, el vivero y la unidad de fauna requieren soluciones robustas, pero con un enfoque centrado en confiabilidad funcional y mantenimiento más que en continuidad absoluta. Por su parte, educación ambiental y alojamiento responden principalmente a lógicas de confort, seguridad de ocupantes y facilidad de operación.

Tabla 5.27 Matriz de Requerimientos de Diseño por Edificio.

EDIFICIO / UNIDAD	CRITICIDAD OPERATIVA	REQUERIMIENTOS ELÉCTRICOS	REQUERIMIENTOS HIDRÁULICOS Y SANITARIOS	HVAC / VENTILACIÓN	TELECOM Y DATOS	SEGURIDAD Y CONTROL	CONDICIONANTES CONSTRUCTIVAS	OPERACIÓN Y MANTENIMIENTO
Administrativo y dirección	Media	Alimentación normal regulada, respaldo parcial para TI y control de accesos	Agua potable, sanitarios, cocineta y drenaje convencional	Confort térmico mixto; ventilación natural asistida y climatización puntual	Red de voz y datos, videoconferencia, control documental	Control de accesos, detección de incendio, CCTV	Protección solar, materiales durables y buena conectividad interna	Operación en horario extendido, mantenimiento convencional
Laboratorios e investigación	Alta	Alimentación estabilizada, UPS para equipos críticos, respaldo por planta, circuitos separados	Agua potable, agua de proceso, drenajes segregados, pretratamiento de efluentes y manejo de residuos	HVAC especializado, extracción localizada, control de humedad y presión diferencial según zonas	Red robusta de datos, conexión a instrumentos, almacenamiento y trazabilidad digital	Acceso restringido, detección y supresión de incendio compatible, gestión de sustancias y bioseguridad	Acabados químicos resistentes, control de corrosión, pisos y superficies lavables	Mantenimiento especializado, calibración, validación y operación continua
Centro de monitoreo ambiental y datos	Alta	UPS, planta de emergencia, transferencia automática, calidad de energía reforzada	Agua y drenaje limitados a servicios; protección contra fugas en áreas sensibles	Climatización de precisión para servidores y centro de monitoreo	Red troncal redundante, fibra óptica, servidores, respaldo y ciberseguridad	Acceso por niveles, CCTV, detección temprana y supresión para equipo electrónico	Alta protección frente a humedad, temperatura e ingreso de agua	Operación 24/7, mantenimiento preventivo de TI y energía
Educación ambiental y vinculación	Baja	Alimentación convencional, respaldo parcial para equipos audiovisuales	Agua potable, sanitarios públicos, cafetería ligera y drenaje convencional	Confort térmico para ocupación pública, ventilación natural y climatización puntual	Red para aulas, auditorio, museo y servicios a visitantes	Rutas de evacuación, control de aforo, accesibilidad universal, detección de incendio	Espacios flexibles, protección solar, resistencia a uso intensivo	Operación programada, limpieza y mantenimiento frecuentes
Alojamiento para investigadores	Baja	Alimentación convencional, respaldo parcial para servicios esenciales	Agua potable, sanitarios, regaderas, lavandería y cocina común	Confort térmico habitacional, ventilación natural asistida y equipos de climatización local	Red básica de datos y comunicación	Control de acceso, detección de incendio y seguridad de ocupantes	Materiales resistentes a humedad, fácil mantenimiento y confort acústico	Operación intermitente, mantenimiento habitacional
Talleres, almacenes y servicios técnicos	Media	Alimentación para herramientas, mantenimiento y carga de equipos, reserva para expansión	Agua para limpieza, servicios y apoyo técnico; drenaje de piso donde aplique	Ventilación natural reforzada y extracción puntual en áreas específicas	Datos para gestión de activos e inventarios	Control de accesos, seguridad industrial, señalización y detección básica	Alta resistencia mecánica, pisos de uso rudo, protección anticorrosiva	Mantenimiento continuo y logística de inventarios
Conservación ecológica y vivero	Media	Alimentación para bombeo, riego, invernadero y equipos ligeros	Alta demanda de agua, riego, drenajes de operación y posibilidad de reúso	Ventilación natural, control microclimático parcial en invernadero y propagación	Datos básicos para monitoreo ambiental y control operativo	Seguridad sanitaria, control de accesos y resguardo de insumos	Estructuras ligeras resistentes al ambiente, superficies drenantes y cubiertas apropiadas	Operación diaria, mantenimiento de riego y estructuras ligeras
Rescate y manejo de fauna	Media	Alimentación para equipos clínicos básicos, refrigeración y soporte sanitario	Agua potable, drenajes controlados, limpieza intensiva y manejo sanitario de efluentes	Ventilación controlada, extracción y confort adecuado para especies y personal	Datos para registro de ejemplares y seguimiento clínico	Bioseguridad, control sanitario, acceso restringido y protocolos de manejo	Materiales lavables, resistentes y de fácil desinfección	Operación continua condicionada, limpieza y control sanitario intensivos
Embarcadero y apoyo operativo	Alta	Alimentación para taller ligero, iluminación, seguridad y equipos de campo	Agua para limpieza, regaderas, sanitarios y apoyo a operación náutica	Ventilación natural predominante y extracción puntual en resguardo de motores	Datos y radio/comunicación para coordinación de campo	Control de accesos, seguridad náutica, iluminación y CCTV	Diseño robusto contra salinidad, humedad, maniobra y variación hidráulica	Mantenimiento frecuente, inspección náutica y resguardo anticorrosivo
Obras complementarias	Alta	Subestación, tableros, planta de emergencia, bombeo, respaldo y distribución troncal	Planta de tratamiento, cisternas, bombeo, redes maestras y manejo especial de residuos	Ventilación técnica en cuartos de instalaciones	Automatización básica, monitoreo de sistemas y enlace al centro de datos			

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Desde la perspectiva eléctrica, la matriz evidencia tres niveles de exigencia. El primero corresponde a los edificios de alta criticidad que requieren alimentación respaldada, segregación de cargas y calidad de energía controlada. El segundo corresponde a edificios operativos de criticidad media que necesitan confiabilidad, capacidad de expansión y seguridad industrial. El tercero corresponde a edificios de uso público o habitacional, donde la prioridad es la seguridad del usuario y el confort. Este escalonamiento permite definir una estrategia general de distribución en la que las redes maestras partan desde obras complementarias con reserva suficiente para crecimiento, y se ramifiquen según niveles de prioridad. En términos conceptuales, esto es consistente con el diseño por jerarquía de cargas y con criterios de continuidad operativa aplicables a infraestructura crítica.

En materia hidráulica y sanitaria, la principal conclusión es que el conjunto no puede resolverse con una sola lógica de red. Los laboratorios y la unidad de fauna requieren corrientes controladas y manejo diferenciado de efluentes; el vivero demanda altos volúmenes para riego y posibilidad de reúso; el embarcadero necesita servicios de apoyo y limpieza; y los edificios administrativos, educativos y de alojamiento responden a esquemas convencionales de ocupación humana. Por tanto, el diseño deberá separar, desde la ingeniería básica, las redes de agua potable, agua de proceso o tratada, drenaje sanitario, drenaje pluvial y corrientes especiales. Este criterio se alinea con buenas prácticas de diseño sanitario y con requerimientos regulatorios asociados a manejo de residuos líquidos y protección ambiental.

En cuanto a climatización y ventilación, la matriz distingue tres familias de edificios. La primera incluye laboratorios y centro de monitoreo, donde se requieren ambientes controlados, extracción localizada, control de humedad y, en algunos casos, precisión térmica. La segunda familia comprende talleres, unidad de fauna y algunas áreas de apoyo, donde la ventilación natural reforzada o la extracción puntual pueden ser suficientes si se combinan con un adecuado diseño pasivo y materiales apropiados. La tercera familia incluye administrativo, educación ambiental y alojamiento, donde la estrategia más eficiente consiste en combinar ventilación natural, protección solar y climatización puntual en áreas de permanencia prolongada. Esta diferenciación permite evitar sobredimensionamientos, optimizar consumos y ajustar el diseño climático a la verdadera exigencia operativa de cada edificio.

Respecto de telecomunicaciones y datos, la matriz muestra que el CIAP debe estructurarse sobre una red digital jerarquizada. El centro de monitoreo y laboratorios requieren el mayor nivel de robustez, capacidad y seguridad, seguidos por administrativo y edificios de apoyo técnico, mientras que los edificios de vinculación, alojamiento y vivero necesitan conectividad funcional pero no crítica. La consecuencia de diseño es que el proyecto debe prever una troncal preferentemente en fibra óptica con redundancia entre nodos críticos, cuartos de telecomunicaciones por edificio y capacidad suficiente para integrar sensores, plataformas analíticas, videovigilancia, control de accesos y automatización técnica.

En seguridad y control, las diferencias entre edificios son igualmente significativas. Laboratorios, monitoreo, fauna, embarcadero y cuartos técnicos exigen accesos restringidos, protocolos específicos y sistemas de control reforzado. En cambio, educación ambiental y alojamiento requieren estrategias de seguridad centradas en aforo, evacuación, accesibilidad y protección del usuario. Esto demuestra que el sistema de seguridad del CIAP no debe resolverse de forma homogénea, sino mediante capas diferenciadas de control físico, operativo y tecnológico.

Las condicionantes constructivas, por su parte, evidencian la necesidad de una estrategia transversal de durabilidad en ambiente costero. Todos los edificios deberán responder a salinidad, humedad, radiación y exposición a eventos de lluvia intensa, pero esta exigencia se vuelve más estricta en embarcadero, talleres, vivero, laboratorios y obras complementarias. En consecuencia, la selección de materiales, recubrimientos, sistemas de fijación, pendientes, sellos y detalles de encuentro debe orientarse desde el anteproyecto a minimizar corrosión, filtraciones, degradación prematura y dificultades de mantenimiento.

Para facilitar la lectura de la información anterior, en la Tabla 5.28, se presenta una síntesis en la que se identifica el nivel relativo de exigencia de cada edificio por sistema técnico principal.

Esta matriz resumida permite establecer con claridad que la ingeniería básica del CIAP debe concentrar sus mayores esfuerzos de definición y coordinación en cuatro frentes: laboratorios, monitoreo, embarcadero y obras complementarias. Estos edificios o unidades condicionan la confiabilidad del sistema completo y deben considerarse prioritarios en estudios especializados, criterios de redundancia, selección de equipos y estrategias de mantenimiento. En segundo término, se ubican la unidad de fauna, el vivero y los talleres, cuya correcta resolución es esencial para el cierre del ciclo ambiental y logístico del centro. Finalmente, los edificios administrativos, de educación ambiental y alojamiento deben diseñarse con criterios robustos, pero más convencionales, cuidando siempre su integración con el resto del campus.

En conjunto, la matriz de requerimientos de diseño por edificio permite consolidar una base técnica verificable para las siguientes etapas del proyecto. Su principal aportación consiste en convertir la lógica funcional del CIAP en criterios concretos de diseño que facilitan la coordinación entre disciplinas, la priorización de inversiones y la transición ordenada hacia la ingeniería básica y el proyecto ejecutivo.

5.12 Matriz de Pre-dimensionamiento de Instalaciones por Edificio

La matriz de pre-dimensionamiento de instalaciones por edificio, ver Tabla 5.29, tiene como objetivo establecer parámetros preliminares de demanda y capacidad para los principales sistemas del Centro de Investigación Ambiental Portuario (CIAP), de modo que el anteproyecto disponga de una base cuantitativa inicial para la transición hacia la ingeniería básica. Estos valores

no deben interpretarse como dimensiones definitivas de proyecto ejecutivo, sino como referencias de diseño que permiten estimar órdenes de magnitud, reservas de capacidad, prioridades de infraestructura y compatibilidad entre disciplinas.

Tabla 5.28 Matriz Resumida de Prioridad de Ingeniería por Edificio.

EDIFICIO / UNIDAD	ELÉCTRICO	HIDROSANITARIO	HVAC	DATOS / TELECOM	SEGURIDAD	DURABILIDAD COSTERA	PRIORIDAD GLOBAL DE INGENIERÍA
Administrativo y dirección	Media	Media	Media	Media	Media	Media	Media
Laboratorios e investigación	Alta	Alta	Alta	Alta	Alta	Alta	Muy alta
Monitoreo ambiental y datos	Alta	Baja	Alta	Alta	Alta	Alta	Muy alta
Educación ambiental y vinculación	Media	Media	Media	Media	Media	Media	Media
Alojamiento para investigadores	Baja	Media	Media	Baja	Media	Media	Baja-media
Talleres, almacenes y servicios técnicos	Media	Media	Baja	Baja-media	Media	Alta	Media
Conservación ecológica y vivero	Media	Alta	Media	Baja	Media	Alta	Media
Rescate y manejo de fauna	Media	Alta	Media	Baja-media	Alta	Alta	Media-alta
Embarcadero y apoyo operativo	Alta	Media	Baja	Media	Alta	Alta	Alta
Obras complementarias	Alta	Alta	Baja	Media	Alta	Alta	Muy alta

Fuente: Elaboración propia, RHG Ingeniería, 2026.

Desde el punto de vista metodológico, el pre-dimensionamiento se apoya en criterios de densidad de ocupación, intensidad de uso, criticidad operativa, tipología de espacios, requerimientos de equipos y experiencia comparada en edificios administrativos, laboratorios, centros de datos, instalaciones de apoyo técnico y espacios de conservación ambiental. Asimismo, se considera el entorno costero del sitio, el esquema de operación por etapas y la necesidad de prever márgenes razonables de crecimiento para una vida útil funcional del conjunto de al menos veinte años.

Tabla 5.29 Matriz de Pre-dimensionamiento Preliminar por Edificio

EDIFICIO / UNIDAD	SUPERFICIE ESTIMADA [m²]	OCUPACIÓN SIMULTÁNEA DE DISEÑO [personas]	CARGA ELÉCTRICA INSTALADA PRELIMINAR [kW]	DEMANDA MÁXIMA PROBABLE [kW]	CONSUMO DIARIO DE AGUA [m³/día]	DESCARGA SANITARIA / ESPECIAL ESTIMADA [m³/día]	REQUERIMIENTO HVAC	TELECOM Y DATOS	NIVEL DE RESPALDO
Administrativo y dirección	1,377.50	12–15	45–65	30–40	1.5–2.5	1.2–2.0	Confort mixto en oficinas y sala de juntas	Red media de voz/datos y gestión documental	Parcial
Laboratorios e investigación	2,976.94	25–30	220–320	150–220	8–15	5–10[5]	Especializado, con extracción, control de humedad y zonas diferenciadas	Red alta para instrumentación, trazabilidad y análisis	Crítico
Monitoreo ambiental y datos	1,435.28	8–12	90–140	70–110	0.8–1.5	0.6–1.0	Precisión para servidores y sala operativa	Red crítica redundante y almacenamiento	Crítico
Educación ambiental y vinculación	813.97	40–80[1]	70–110	45–75	3.0–5.0	2.4–4.0	Confort para auditorio, aulas y museo	Red media para audiovisual, público y operación	Parcial
Alojamiento para investigadores	1,041.91	18–24	35–60	25–40	4.0–6.5	3.2–5.2	Confort habitacional	Red básica-media para usuarios y gestión	Parcial
Talleres, almacenes y servicios técnicos	352.16	6–10	50–90	35–60	1.0–2.0	0.8–1.5[6]	Ventilación natural reforzada y extracción puntual	Red baja-media para inventario y operación	Prioritario
Conservación ecológica y vivero	315.85	6–10	40–80	25–50	10–20[3]	1.0–2.0[7]	Microclimático parcial en invernadero y propagación	Red baja para control operativo	Prioritario
Rescate y manejo de fauna	431.67	4–6	30–55	20–35	2.5–5.0	1.5–3.0[8]	Controlado, con ventilación y extracción sanitaria	Red baja-media para registro y seguimiento	Prioritario
Embarcadero y apoyo operativo	300	4–8	25–50	18–35	1.5–3.0	1.0–2.0	Predominio natural con extracción puntual en áreas técnicas	Comunicaciones de campo, radio y red media	Prioritario
Obras complementarias	650	3–6	180–300[2]	120–220	2.0–4.0[4]	Variable según subsistemas	Ventilación técnica en cuartos de instalaciones	Monitoreo técnico e integración con centro de datos	Crítico

Nota: (1) Según evento
(2) Asociados a infraestructura troncal y respaldo
(3) Más riego intensivo
(4) Operativos, sin incluir caudal total tratado
(5) Sanitarios más corrientes especiales por proceso
(6) Más posibles drenajes de limpieza
(7) Sanitarios más escurrimientos de operación
(8) Más corrientes sanitarias de limpieza controlada

Fuente: Elaboración propia, RHG Ingeniería, 2026

Para fines de esta matriz, los parámetros se expresan en términos preliminares de carga eléctrica instalada, demanda máxima probable, consumo diario de agua, descarga sanitaria estimada, necesidades relativas de climatización, requerimientos de telecomunicaciones y nivel de respaldo recomendado. Cuando la naturaleza del edificio lo exige, se distinguen además requerimientos especiales asociados a agua de proceso, extracción localizada, continuidad operativa o redes segregadas. Los valores deberán verificarse y refinarse en la siguiente fase mediante memorias de cálculo, catálogos de equipo, definición de ocupación real y estrategia operativa por turnos.

5.12.1 Criterios base de estimación

La estimación preliminar de energía se basa en la combinación de carga por superficie, carga por ocupación y carga por equipos específicos. En edificios de uso convencional, como administración, educación ambiental y alojamiento, el criterio dominante es la ocupación y el acondicionamiento de confort. En laboratorios, monitoreo, talleres y embarcadero, la variable dominante es la presencia de equipos especializados, extracción, bombas, comunicaciones y continuidad operativa. En vivero y fauna, la demanda depende adicionalmente de sistemas de riego, refrigeración, ventilación y soporte clínico o biológico.

En materia hidráulica, la demanda de agua se estima combinando consumo humano, servicios sanitarios, limpieza, procesos especiales y, en su caso, riego o atención clínica. La descarga sanitaria se considera como proporción del consumo total, con correcciones cualitativas para edificios donde parte del agua se destina a riego, lavado técnico o procesos que exigen manejo diferenciado. En edificios críticos, como laboratorios y unidad de fauna, no toda descarga puede considerarse sanitaria convencional, por lo que será necesario confirmar en ingeniería básica qué fracciones requieren tratamiento previo o conducción separada.

Respecto de climatización, el pre-dimensionamiento se plantea en categorías relativas que reflejan la intensidad de control ambiental requerida. Se distinguen edificios con climatización de confort, edificios con climatización especializada y extracción localizada, y edificios con control ambiental de precisión. De forma complementaria, la infraestructura digital se clasifica por nivel de exigencia entre conectividad básica, conectividad reforzada y red crítica redundante. Finalmente, el respaldo se estructura en cuatro niveles: sin respaldo especial, respaldo parcial, respaldo prioritario y continuidad crítica con UPS y planta.

5.12.2 Interpretación técnica de los parámetros preliminares

La matriz precedente permite identificar que el conjunto del CIAP puede agruparse en tres categorías de exigencia electromecánica. La primera corresponde a los edificios de alta intensidad técnica, integrados por laboratorios, monitoreo y obras complementarias, donde las cargas instaladas son significativamente mayores y la continuidad operativa se vuelve un criterio

dominante. La segunda agrupa edificios de soporte técnico y ambiental, como talleres, vivero, fauna y embarcadero, que presentan demandas moderadas, pero con requerimientos específicos de robustez, extracción, bombeo o apoyo logístico. La tercera reúne edificios de ocupación convencional, como administración, alojamiento y educación ambiental, en los que la demanda depende principalmente de confort, servicios y equipamiento general.

En términos eléctricos, el mayor peso del conjunto recae en laboratorios, centro de monitoreo y obras complementarias. Esto sugiere que el dimensionamiento preliminar de la infraestructura troncal deberá considerar una capacidad global instalada del orden de 785 a 1,270 kW, con una demanda máxima probable agregada del orden de 538 a 885 kW, antes de aplicar factores definitivos de simultaneidad, crecimiento y contingencia. A nivel de anteproyecto, esta lectura indica que el CIAP requerirá una acometida o subestación propia, una arquitectura de distribución seccionada por criticidad y al menos una estrategia de respaldo que combine UPS y planta de emergencia para cargas seleccionadas. La cifra exacta deberá ajustarse en la siguiente etapa, pero la escala de demanda ya confirma que no se trata de un equipamiento menor, sino de una instalación científico-portuaria con requerimientos eléctricos de campus técnico.

En materia hidráulica, la lectura preliminar indica una demanda base diaria sin riego intensivo del orden de 34.3 a 64.5 m^3/día, a la que debe añadirse el consumo específico del vivero y de eventuales procesos de laboratorio. En consecuencia, la infraestructura hidráulica del centro deberá contemplar cisternas de regulación, sistemas de bombeo, sectorización por usos y, de manera muy importante, diferenciación entre agua potable, agua de servicio y agua tratada para reúso. El vivero, por su intensidad de riego, y laboratorios, por sus requerimientos de proceso, condicionan de manera importante el diseño general. La presencia de una planta de tratamiento en las obras complementarias, ya prevista en el programa preliminar, se vuelve por tanto un elemento central no sólo para cumplimiento ambiental, sino también para eficiencia operativa y reutilización de agua.

Desde el punto de vista de drenaje y descargas, la matriz confirma que la ingeniería básica deberá separar con claridad tres familias de corrientes: las sanitarias convencionales, las asociadas a limpieza o lavado técnico, y las corrientes especiales sujetas a control o pretratamiento. Esta conclusión es particularmente relevante para laboratorios y unidad de fauna, donde no puede asumirse que toda descarga sea compatible con un sistema convencional sin tratamiento intermedio. De igual modo, los escurrimientos y retornos del vivero deben integrarse a una estrategia hidráulica que minimice pérdidas, erosión o descargas no controladas.

En climatización, el pre-dimensionamiento refleja una gradiente de complejidad que debe respetarse en el diseño. Laboratorios requieren sistemas especializados con extracción localizada y control diferenciado por zonas. El centro de monitoreo exige climatización de precisión para servidores y estabilidad para áreas de operación continua. Fauna demanda ventilación y extracción con criterios sanitarios. En el resto del conjunto, la estrategia más eficiente consiste en maximizar el desempeño pasivo del edificio y reservar la climatización mecánica para espacios de

permanencia prolongada o alta densidad de ocupación. Este enfoque es consistente con criterios de diseño bioclimático, eficiencia energética y diseño basado en desempeño.

En telecomunicaciones y datos, la matriz confirma que el núcleo digital del CIAP deberá articularse a partir del centro de monitoreo, con una red crítica redundante hacia laboratorios y enlaces funcionales al resto de edificios. La consecuencia directa es que el proyecto debe prever ducterías, cuartos de telecomunicaciones, nodos intermedios, protección física de rutas y escalabilidad suficiente para integrar analítica, monitoreo remoto, control de accesos, videovigilancia y plataformas de divulgación.

Tabla 5.30 Síntesis de prioridad de Pre-dimensionamiento por Sistema.

SISTEMA	EDIFICIOS CONDICIONANTES	IMPLICACIÓN PRINCIPAL PARA INGENIERÍA BÁSICA
Eléctrico	Laboratorios, monitoreo, obras complementarias	Definir subestación, jerarquía de cargas, respaldo y crecimiento
Hidráulico	Vivero, laboratorios, fauna, alojamiento	Definir cisternas, sectorización, reúso y redes diferenciadas
Sanitario / especial	Laboratorios, fauna, talleres	Definir pretratamiento, segregación de corrientes y manejo especial
HVAC	Laboratorios, monitoreo, fauna, educación ambiental	Definir tipologías de climatización y ventilación por criticidad
Telecom y datos	Monitoreo, laboratorios, administrativo	Definir troncal redundante, nodos y reserva tecnológica
Respaldo	Monitoreo, laboratorios, obras complementarias, embarcadero	Definir cargas esenciales, UPS, planta y transferencia

1.0 INTRODUCCIÓN

El presente informe parcial desarrolla los criterios técnicos y constructivos asociados al proyecto de dragado requerido para la habilitación de las áreas de navegación del Puerto Nuevo Manzanillo–Cuyutlán, considerando las condiciones físicas, geotécnicas y operativas propias de la Laguna de Cuyutlán.

El dragado constituye una actividad fundamental para garantizar la operatividad portuaria, permitiendo definir las profundidades, geometrías y condiciones de seguridad necesarias para la navegación, maniobra y permanencia de embarcaciones de gran calado. En este sentido, el proyecto contempla el análisis integral de factores relacionados con el buque de diseño, las condiciones hidrodinámicas (oleaje, corrientes y mareas), así como las características del fondo marino y las tolerancias constructivas.

Adicionalmente, se consideran los condicionantes asociados a la naturaleza de los suelos presentes en la zona, los cuales incluyen estratos arcillosos de baja resistencia, arenas de compacidad media y materiales altamente densos o geomateriales, lo que influye directamente en la selección de equipos, procedimientos constructivos y estrategias de aprovechamiento del material dragado.

El informe también integra la definición de las áreas de navegación —canales de acceso, dársenas de maniobra y canales interiores—, así como la estimación de volúmenes de dragado y relleno, con el objetivo de garantizar condiciones seguras de operación y optimizar el uso de los materiales generados durante la ejecución de las obras.

2.0 OBJETIVOS.

2.1 Objetivo Principal.

El objetivo principal de los servicios descritos en el presente documento es:

- Definir los criterios técnicos para el diseño y ejecución de los trabajos de dragado en la Laguna de Cuyutlán, incluyendo la determinación de profundidades, geometrías de las áreas de navegación, caracterización de materiales y estimación de volúmenes, con el fin de garantizar condiciones seguras y eficientes para la operación portuaria.

2.2 Objetivos Particulares.

Los objetivos particulares de los servicios descritos en el presente documento son:

- Analizar los factores condicionantes del dragado, incluyendo aspectos geotécnicos, ambientales, operativos y relacionados con el tráfico marítimo.
- Caracterizar los materiales presentes en el subsuelo, clasificándolos con fines de dragado y definiendo su potencial aprovechamiento.
- Establecer criterios para la determinación de taludes de excavación en función de la resistencia de los materiales.
- Definir la configuración geométrica y dimensiones de las áreas de navegación, considerando el buque de diseño y las condiciones de operación.
- Determinar las profundidades requeridas para garantizar la seguridad de la navegación, incluyendo márgenes de resguardo bajo quilla.
- Estimar los volúmenes de dragado y relleno, así como identificar el balance de materiales y su posible reutilización.
- Proponer criterios de diseño que permitan optimizar la operación portuaria y reducir costos de mantenimiento asociados al dragado.

3.0 PROYECTO DE DRAGADO Y RELLENOS.

El dragado es una actividad básica e imprescindible para la operatividad portuaria y costera, tanto desde el punto de vista de la construcción de obras y creación de nuevas infraestructuras, como desde el de la explotación y operación de las ya existentes.

El proyecto de dragado contempla los criterios para la determinación de las profundidades de agua en las diferentes áreas de navegación en la Laguna de Cuyutlán, considerando tanto los factores relacionados con el buque (trimados, resguardos para movimientos del buque por vientos, oleajes, corrientes y cambios de rumbo, resguardos para seguridad y control de la navegación, etc.) como los relacionados con el nivel de las aguas (mareas astronómicas y meteorológicas, regímenes fluviales, etc.), y los que dependen del fondo (imprecisiones de la batimetría, depósitos de sedimentos y tolerancia de ejecución del dragado).

3.1 Generalidades.

La profundidad de agua necesaria en las diferentes áreas de navegación y flotación son variables, teniendo en cuenta la vida útil de la ampliación hacia el interior de la Laguna de Cuyutlán, las condiciones de operatividad admitidas para la misma, las características y distribución del tráfico de buques, los costos de construcción y mantenimiento.

Las profundidades del agua que se han sido adoptados en el proyecto permiten que, durante todo el tiempo, condiciones de operatividad seguras, la navegación, maniobras, permanencia y carga o descarga de los buques, en condiciones de seguridad, para todos los barcos que utilicen dichas áreas de navegación y flotación.

3.2 Factores Condicionantes.

Los principales factores condicionantes de la forma en que se ejecutarán las obras de dragado son, por una parte, la calidad del terreno y las características técnicas de los equipos de dragado y, por otra, el tipo de obra a realizar y el medio físico donde se llevaran a cabo. A ello se le añaden otros factores que en un momento dado pueden resultar claves como, la proximidad de zonas urbanas, las regulaciones ambientales, determinadas circunstancias asociadas al tráfico marítimo, etc. Analizando estos factores, tenemos lo siguiente:

3.2.1 Características del desarrollo portuario.

Los condicionantes impuestos por el desarrollo portuario son de gran importancia y conviene dedicarles un estudio preliminar. Dentro de estas características, hay que tener en cuenta, al menos, las siguientes:

- Las condiciones físicas de la zona de dragado: Entre las condicionantes físicos está, en primer lugar, el clima marítimo del emplazamiento del dragado (el oleaje y las corrientes que influyen en la capacidad de movimiento, potencia instalada y en la fijación y el movimiento de los equipos de dragado y mareas que pueden dificultar las tareas de excavación del suelos) y, en segundo lugar, los factores meteorológicos (los vientos reinantes, la posibilidad de precipitaciones torrenciales que provoquen avenidas o desbordamientos, las nieblas) y por último las condiciones físicas del terreno (dimensiones, profundidad, rellenos, etc.).

- La naturaleza de los terrenos: Los tipos de suelo a los que se puede enfrentar una obra de dragado comprenden prácticamente todos los que nos podemos encontrar en la naturaleza. Por lo tanto, nos encontramos con una amplia variedad de suelos en cuanto a composición, estructura, dureza, densidad, granulometría, etc. Es fundamental un conocimiento perfecto de los suelos a dragar ya que esto repercutirá sobre el tipo de equipos a utilizar en la excavación, el transporte de productos y en los medios y elección de lugares para su vertido.

- La proximidad a zonas habitadas: La proximidad a zonas habitadas suele influir negativamente en el desarrollo de la obra. De hecho, puede ser un impedimento para la realización de este tipo de obras por los inconvenientes que suponen para la población (malos olores, ruidos, etc.) y la dificultad para encontrar zona para verter el material. Este último problema puede llevar a que la obra se encarezca de manera importante por la necesidad de buscar zonas para verter el material lejano a la obra de dragado, con el consiguiente incremento del costo de transporte que ello conlleva. Otro impedimento que se puede encontrar la obra de dragado por la proximidad a zonas terrestres son los permisos correspondientes.

- El tráfico marítimo que soporta la zona afectada: El último condicionante mencionado se refiere a la densidad del tráfico marítimo existente en la zona. Este condicionante tendrá más peso en el dragado de canales estrechos y en canales de acceso con gran frecuencia de tráfico. Cuando más tráfico marítimo nos encontremos, más dificultosa será la organización y el control de las obras de dragado, para minimizar los contratiempos en el devenir normal de la actividad marítimo-portuaria.

3.2.2 Condicionantes ambientales.

Un análisis medioambiental de la zona de dragado y el impacto que este tipo de obras tendrá en los ecosistemas de la zona, será una condición sin la cual, en la mayoría de los casos, no se podrá ejecutar este tipo de obra. Cada vez es un condicionante de mayor peso por la exigencia de la sociedad en su conjunto de respeto al medio natural. Bien es verdad que, en otras ocasiones,

como por ejemplo en la limpieza de fondos contaminados o limpieza de humedales, las obras de dragado pueden ser una herramienta de protección del medio ambiente.

Por otra parte, hay que tener en cuenta que estas obras no solo afectan a la zona de dragado, sino que hay que evaluar el impacto del transporte y el vertido de los productos, bien en vertidos en el mar abierto o en cauces de ríos.

3.2.3 Características y limitaciones técnicas de los equipos de dragado.

El tipo de obra y la zona de proyecto de esta y las características de los equipos de dragado, la manera de organización del trabajo interactúa de manera reciproca. Por lo tanto, los equipos de dragado deben estar plenamente adaptados al tipo de obra y a la zona de proyecto, pudiendo un equipo particular resultar ideal para un tipo de obra y, sin embargo, no ser apto para la realización de otro

Por último, es importante comentar, que, en las obras de dragado, el condicionante más decisivo es el tipo de barco que utilizará las instalaciones portuarias de la ampliación en la Laguna de Cuyutlán y las características de este: dimensiones (eslora, manga y calado), condiciones de maniobrabilidad y necesidades de superficie de fondeo. En la planificación de la ampliación se deberá tener en cuenta, como base de los cálculos, el barco máximo que deba entrar a puerto junto con las características que se fijen para la navegación. Asimismo, la profundidad a que debe dragarse las áreas de navegación se estimará teniendo en cuenta que se deberá disponer en todo momento y circunstancia la profundidad para que la navegación del buque en la zona portuaria sea segura siempre deberá existir una profundidad de agua adecuada por debajo del buque denominada zona de resguardo. De todas maneras, al ser muy costoso el aumento de profundidades, se suele restringir al mínimo compatible con la seguridad de navegación, teniendo en cuenta las mareas de la zona de proyecto o la ausencia de grandes oleajes durante la mayor parte del año. Además, hay que tener en cuenta que los cálculos se realizan para el mayor buque posible, mientras que la mayoría de los puertos proporcionan servicio para buques de menor envergadura.

De acuerdo con las características del buque máximo se tendrán que proyectar las secciones y plantas de las distintas vías de acceso interiores y superficies de maniobra, mientras que las dársenas y zonas de fondeo se planifican según el tráfico y las características de los buques que la utilizan.

3.3 Características de los Suelos por Dragar.

Las obras de dragado son normalmente complejas y caras. Muchas veces constituyen el componente económico principal de las obras marítimas. Para poder proyectar de forma

adecuada las obras de dragado se requiere un buen conocimiento del material a dragar y de los condicionantes ambientales.

De acuerdo con el estudio de mecánica de suelos desarrollado, la estratigrafía encontrada en la zona de proyecto permite reconocer tres formaciones principales, la más superficial está conformada generalmente por depósitos arcillosos de consistencia errática, muy blanda a muy firme, que se prolonga a una profundidad que oscila entre -3.5 y -5.5 m.

Le siguen suelos arenosos mayormente medianamente compactos que se extienden a una profundidad que varía entre -5.5 y -8.8 m. Finalmente aparece el Estrato Resistente constituido por arenas muy compactas, dando lugar incluso a reconocerlos como geomateriales[1], con algunos estratos compactos no continuos, que se prolonga hasta el final de los sondeos, o sea más allá de -31 m.

Las características de las tres formaciones principales encontradas se describen a continuación.

Formación 1: Suelos arcillosos de resistencia errática: muy blanda a muy firme
- horizonte superior: nivel del fondo actual, entre -0.3 y -2.8 m
- horizonte inferior: entre -3.5 y -5.8 m
- espesor: entre 3.2 y 5.30 m
- material: Arcilla o arcilla muy poco arenosa (CH) color café gris, gris o gris oscuro, con vestigios de concha. Su consistencia es errática ya que va de muy blanda a muy firme.

Formación 2: Suelos arenosos medianamente compactos
- horizonte superior: entre -3.5 y -5.8 m
- horizonte inferior: entre -5.5 y -8.8 m
- espesor: entre 1.2 a 5.0 m
- material: Arena mal graduada (SP, SP-SM), mayormente en estado medianamente compacto con estratos sueltos a compactos no continuos, color café gris, gris o gris oscuro, con poca pedacería de concha.

Formación 3: Arena muy compacta (geomaterial)
- horizonte superior: entre -5.5 y -8.8 m

[1] El término de geomaterial se aplicó por primera vez por O'Neill et al. (1996) con el fin de distinguir los materiales con propiedades de resistencia que son intermedias entre el suelo de alta resistencia y una roca suave.

horizonte inferior:	más allá de -30.9 m
espesor:	mayor de 23 m
material:	Asociado al Estrato Resistente[2] se encuentran arenas mal graduadas (SP, SP-SM) color café gris, gris claro o gris oscuro, en estado muy compacto (geomaterial), con algunos estratos compactos no continuos en los sondeos S-04 y S-06, con poca pedacería de concha.

3.3.1 Clasificación con Fines de Dragado.

De acuerdo con la descripción estratigráfica expuesta anteriormente, en la Tabla 3.1 se expone la clasificación del material sujeto a dragado acorde a los dos criterios de clasificación elegidos, teniendo como punto de partida la clasificación SUCS.

Tabla 3.1 Clasificación del Material con Fines de Dragado.

Profundidad (m)	Clasificación		
	SUCS	USACE	SCT
Inicia desde la superficie y se extiende hasta una profundidad variable entre -3.5 y -5.8 m, con un espesor de 1.2 y 3.0 m	Arcilla o arcilla muy poco arenosa (CH) color café gris, gris o gris oscuro, con vestigios de concha. Su consistencia es errática ya que va de muy blanda a muy firme.	Grupo C Cohesive Soils (Suelos Cohesivos)	Material A a C
Entre -3.5 y -5.8 m y se prolongan entre -5.5 y -8.8 m, con un espesor de 1.2 a 4.0 m.	Arena mal graduada (SP, SP-SM), mayormente en estado medianamente compacto con estratos sueltos a compactos no continuos, color café gris, gris o gris oscuro, con poca pedacería de concha.	Grupo G Clean Granular Soils (Suelos Granulares Limpios)	Material A a C
Desde las cotas -5.5 y -8.8 m, continúa hasta la profundidad de dragado de -16.5 m.	Asociado al Estrato Resistente se encuentran arenas mal graduadas (SP, SP-SM) color café gris, gris claro o gris oscuro, en estado muy compacto (geomaterial).	Grupo G Clean Granular Soils (Suelos Granulares Limpios)	Material A a C

Fuente: Elaboración propia, 2026.

[2] Se define como Estrato Resistente (ER) aquel donde de manera predominante se tiene un número de golpes en la prueba de penetración estándar N>50, y que se mantienen de manera sostenida en un espesor de al menos 10 m.

Se recurre a dos criterios para clasificar el material por dragar que se mencionan a continuación:

- Según USACE

  En base al Sistema para la Clasificación de Sedimentos por Dragar elaborado por el Cuerpo de Ingenieros del Ejército de los Estados Unidos[3] (US Army Corps of Engineers, USACE).

  También se tomó en cuenta lo expresado en el Manual de Ingeniería: Dragado y Gestión de Materiales de Dragado[4]. Vale la pena destacar que el USACE promueve la clasificación del suelo en base al SUCS.

- Según antiguo criterio de la SCT.

  La Secretaría de Comunicaciones y Transportes (SCT) estipula hoy en día en su norma N-CTR-PUE-1-03-001/06, de noviembre de 2006, relativa al dragado con equipo marino, que cuando la obra se contrate a precios unitarios por unidad de obra terminada, no se clasificará el material por excavar, siendo esto responsabilidad exclusiva del Contratista de Obra. Por esta razón, lo que aquí se expone tiene un carácter meramente de referencia y aprovecha lo asentado antes por la propia SCT[5] con fines de dragado, en que los materiales por dragar se clasificaban como tipos A, B, C y D.

El significado de la clasificación otorgada con letras por la USACE y por la antigua clasificación de la SCT se explica a continuación.

- Criterio USACE:

  a. Grupo C: Cohesive Soils (Suelos Cohesivos):

     – Propiedades geotécnicas: Éstos son suelos masivos de grano fino, por lo general arcillas firmes a duras y arcillas limosas de media a alta plasticidad. No son frágiles. Tienen suficiente densidad y contenido de arcilla para reportar

[3] Department of the Army, Waterways Experiment Station, Corps of Engineers, Material Properties Related to Navigation and Dredging: Summary Report for Technical Area 2, Dredging Research Program, Technical Report DRP-95-7, September 1995, Washington, DC.

[5] Secretaría de Comunicaciones y Transporte, Normas para Construcción e Instalaciones, Costas y Puertos, Obras Marinas, Obras Portuarias e Instalaciones, Libro 3, Parte 3.03, Título 3.03.02, México 1984.

resistencia a la compresión no confinada. Exhiben plasticidad, cohesión y resistencia en seco. Poco o ningún contacto entre granos; la resistencia al esfuerzo cortante se deriva de la densidad, historia de esfuerzos, y la cantidad y tipo de arcilla.

- Propiedades de excavación: No es frágil (no se desmorona fácilmente); no se succiona o erosiona; puede ser excavado mediante el corte o paleo. Los taludes submarinos son generalmente muy estables, excepto en las arcillas blandas.

- Propiedades para la extracción y transporte: Probablemente se formen terrones durante el transporte mecánico o bolas de arcilla en las tuberías hidráulicas. Baja abrasión en la tubería. No se asienta con rapidez en la tolva, por lo general se desborda.

- Propiedades del depósito: A menudo pegajoso cuando el contenido de agua es alto, Toma bastante tiempo para asentarse en la zona de depósito. La cohesión de la arcilla impide la densificación del suelo con vibraciones. El abundamiento es bastante alto.

b. Grupo G: Clean Granular Soils (Suelos Granulares Limpios)

- Propiedades geotécnicas: El material es grava, arena o limo con poca o ninguna plasticidad; no conservará su estructura si se seca. La fuerza cortante se deriva de su densidad relativa, de la angularidad del grano, y la falta de finos.

- Propiedades de excavación: Se excava fácilmente bajo la erosión hidráulica (socavación). Tiene alta fragilidad. Fácil de cortar o socavar. Los taludes no son estables; tienden a fluir fácilmente bajo agua hasta su ángulo de reposo.

- Propiedades para la extracción y transporte: Fácilmente removible y transportable hidráulicamente. Las partículas se asientan muy rápidamente en una tolva. Fácilmente transportables en forma de lodo o mezcla acuosa en tuberías, la energía requerida es función del tamaño del grano medio. Las partículas grandes contribuyen al desgaste de la tubería. Los factores de abundamiento son bajos.

- Propiedades del depósito: Se descarga con facilidad. Se asienta rápidamente en el área de depósito. Los suelos granulares limpios (con pocos o nada de finos plásticos) se densificarán con vibraciones. Normalmente no responden bien a la compactación mecánica.

- Criterio SCT:

  a. Material A: Se clasifican así los limos y fangos (arcillas blandas con materia orgánica).

  b. Material C: Se clasifican así las arenas, gravas, conchuelas y arcillas medianamente compactas.

  c. Material D: Se clasifican así las arenas, gravas, conchuelas y arcillas cementadas.

3.3.2 Empleo del Material de Dragado

Se distinguen dos tipos de material por remover, a saber:

a. El material por extraer hasta las cotas -4 y -6 m, aproximadamente, es arcilla o arcilla muy poco arenosa (CH) color café gris, gris o gris oscuro, con vestigios de concha. Su consistencia es errática ya que va de muy blanda a muy firme. Por lo tanto, no se recomienda que este material removido NO SEA empleado en la conformación de ningún tipo de relleno estructural, por lo que deben retirarse del lugar y depositarse en el sitio adecuado para este fin.

b. Después, hasta la cota de dragado de -16.5 m., aparecen Arena mal graduada (SP, SP-SM), mayormente en estado medianamente compacto con estratos sueltos a compactos no continuos, color café gris, gris o gris oscuro, con poca pedacería de concha, que se extiende entre las cotas -6 y -9 m, aproximadamente. Después, y asociado al Estrato Resistente, arenas mal graduadas (SP, SP-SM) color café gris, gris claro o gris oscuro, en estado muy compacto (geomaterial). Por lo que el uso de este material puede ser el siguiente:

   - Conformación de rellenos estructurales.
   - Construcción de terracerías y capa subrasante dentro de la estructura de pavimentos.
   - Rellenos de zanjas para instalaciones y de cimentaciones superficiales.

Respecto al abundamiento del material, se debe tomar en cuenta que al estimar el volumen para el diseño de terrenos ganados al mar, por ejemplo, se deben prever correcciones por el efecto de abundamiento del material.

En nuestro caso y cuando se usa draga mecánica es de esperarse el siguiente abundamiento:

a. Factor de abundamiento de 1.0 a 1.1, para el material por extraer aproximadamente hasta las cotas -4 y -6 m, formado por arcilla o arcilla muy poco arenosa muy blanda a muy firme.

b. Factor de abundamiento de 1.15 para la arena generalmente en estado medianamente compacto que se extiende hasta las cotas -6 y -9 m, aproximadamente.

c. Factor de abundamiento de 1.25 a 1.35, para el Estrato Resistente constituido por arenas mal graduadas en estado muy compacto (geomaterial), que se prolonga hasta la cota de dragado de -16.5 m.

3.3.3 Talud Recomendado para el Dragado.

Como referencia, en la Tabla 3.2 se muestran los taludes submarinos recomendados en la literatura técnica.

Tabla 3.2 Talud Submarino Recomendado.

Tipo de suelo	Canadian Coast Guard(*)	Department of the Navy(**)	Institution of Civil Engineers(***)
Roca firme	1:1	–	Casi vertical
Roca fisurada	1:1	–	–
Grava cementada o arcilla dura	1:1	–	1.2:1
Arcilla con gravas, firme	1:1	–	–
Arcilla firme	1.5:1	1:1	1.2:1
Arcilla arenosa	–	–	3.7:1
Grava arcillosa	1.5:1	1:1 y 2:1	–
Arena arcillosa, suelta	2:1	–	2.1:1
Arena y gravas sin o con pocos finos	3:1 y 4:1	2:1 y 5:1	–

En base a los análisis antes expuestos, para efectuar el dragado a las cotas de proyecto de las áreas de navegación en la Laguna de Cuyutlán se recomienda lo siguiente:

a. Adoptar en el dragado un talud compuesto por dos pendientes:

    1. Talud en los suelos de resistencia baja a moderada que sobreyacen el estrato resistente, y

    2. El talud mismo del estrato resistente compuesto por arena muy compacta (geomaterial).

b. Para el del suelo sobreyacente el talud no debe ser menor de 4:1 (H:V), por lo tanto, considerando los taludes naturales en la zona que actualmente se encuentra dragada en el interior de la laguna, se propone un talud de 6:1 (H:V). De acuerdo con la estratigrafía encontrada en el frente de atraque estos suelos se prolongan desde el fondo lagunar hasta una profundidad que oscila entre -2.00 y -10.60 m.

c. En el estrato resistente se propone que el talud sea de 3:1 (H:V). Dada la alta resistencia de este material se considera que el equipo de dragado debe ser capaz de identificar el contacto con este material y entonces modificar la inclinación del talud.

d. Para el caso donde se encuentra roca, se recomienda adoptar un talud de 1.5 :1 (H:V).

3.4 Áreas por Dragar.

El desarrollo portuario en la Laguna de Cuyutlán con su disposición en planta y de los canales de acceso, áreas de maniobra y dársenas, deben garantizar unas condiciones de operatividad y seguridad mínimas.

La definición correcta de un área de navegación o fondeo precisa la determinación de los elementos siguientes:

- La configuración geométrica de los espacios de agua y terrestres utilizados, mediante las definiciones precisas en planta y alzado de ejes, alineaciones, curvas, cotas, niveles y cuantos elementos sean necesarios para una determinación inequívoca de tales espacios.

- El balizamiento de señalización marítima que se prevea instalar para la identificación «in situ» de tales espacios, cuya definición deberá ser especialmente concreta en el caso de que se haya afinado el dimensionamiento basándose en la precisión de determinadas ayudas a la navegación.

- Las condiciones climáticas marítimas y atmosféricas límites que permitan la utilización de las áreas de navegación o fondeo en condiciones normales de operación. Estas condiciones podrán ser diferentes según e tipo y dimensiones de los buques, los remolcadores disponibles, o en función de cualquier otra condición particular que se haya definido en cada caso.

- Los requerimientos básicos de remolque que se precise disponer para la utilización de las áreas de navegación o fondeo por determinados tipos de buque, asociados a las condiciones climáticas en que puedan desarrollarse estas maniobras en condiciones normales de operación.

Un área de navegación o fondeo no queda definida, por tanto, solamente por sus características geométricas y su balizamiento, sino también por sus condiciones operativas y por la necesidad o no de utilización de remolcadores u otras ayudas a la navegación, circunstancias que determinan, no sólo el que pueda disponerse de mayores o menores porcentajes de tiempo aptos para la operación de los buques, sino también las propias dimensiones de los espacios de agua requeridos.

Por tal motivo, el procedimiento recomendado para la definición de las áreas de navegación en el interior de la Laguna de Cuyutlán es el siguiente:

- Establecer las características de la flota de buques que operará en la zona en los diferentes años a futuro que vayan a considerarse dentro de la vida útil; en general se dispondrá de la siguiente flota atendiendo a las previsiones de tráfico.

  En este caso en particular, la flota de buques portacontenedores de diseño, se compone de 3 buques:

  – Maxi Neo-Panamax [Eslora = 369 m, Manga = 51.2 m y Calado = 15 m], buque de mayores dimensiones que ha pasado por las nuevas esclusas de Panamá, cargando hasta 14.500 TEU’s.

  – Nuevos Clase E [Eslora = 398 m, Manga = 56 m y Calado = 15.5 m], buques con hasta 21.000 TEU’s de capacidad.

  – Megamax 24 (MGX24), [Eslora = 400 m, Manga = 61.5 y Calado = 16.5 m (max = 17.7 m)], buques con hasta 24.000 TEU’s de capacidad.

  Siendo el buque MGX24, por sus dimensiones, el más relevante para el diseño de las áreas de navegación.

- Prefijar las condiciones climáticas marítimas y atmosféricas límites para las distintas maniobras de buques que puedan desarrollarse en la zona que se considere. Estas condiciones se muestran en la tabla 3.3.

  Considerando el clima local es posible establecer las condiciones climáticas para el dimensionamiento de las áreas de navegación.

Tabla 3.3 Condiciones Físicas.

Oleaje (Dirección / Hs)	**Viento** Dirección / Velocidad)	**Corriente Superficial**	
		Exterior Dirección / Velocidad)	**Interior** (Velocidad)
SSW / 2.0 m	NNE – SE – SSW – WNW / 20 nudos	ESE – WNW / 2.0 nudos	0.50 nudos

Fuente: Elaboración propia, 2026.

De acuerdo con la información del viento y a las características del área de proyecto se consideran las siguientes direcciones de análisis:

– Por su alta frecuencia de presentación se consideran las direcciones NNE y WNW, donde la primera no tiene gran influencia en el acceso al puerto, debido a su alineamiento con el canal Tepalcates y su baja intensidad. La segunda complica la maniobra debido a su transversalidad al canal de acceso.

– Por su elevada intensidad se consideran las condiciones SE y SSW, donde la primera complica la maniobra debido a su dirección transversal y la segunda perjudica la parada del buque en la dársena de ciaboga, al incidir por popa en el canal de acceso.

Con base a la información del oleaje disponible, se considera un único escenario de referencia por su alta frecuencia de presentación, con oleaje SSW de 14 segundos de periodo (periodo de pico promedio), considerando una altura de ola significante de referencia de 2.0 m, debido a la complejidad que supone tanto para la conexión como para la operación de los remolcadores.

El nivel de agua no se considera un factor relevante para el estudio, por lo que, de forma genérica, se considera el valor del nivel de bajamar medio inferior (0.0 m), que, además, reduce el resguardo bajo quilla, siendo por lo tanto una situación desfavorable para la navegación.

Según la conversación mantenida con los Prácticos locales se ha confirmado la siguiente información relativa a la corriente:

- Las corrientes son paralelas a la costa, en los dos sentidos, y completamente transversales al canal de acceso. No se ha podido determinar estacionalidad o dependencia en la dirección del oleaje con otros factores.

- La intensidad máxima de la corriente observada es de unos 2.5 nudos, y esta ocurre tras un fuerte temporal, y la mínima de unos 0.2 nudos. La velocidad de la corriente, de forma general, suele encontrarse en valores entre 0.5 nudos y 1.5 nudos.

- Una vez el buque ha superado los espigones no se aprecia corriente.

- En ocasiones, la dirección de la corriente varía significativamente entre la recalada y el canal de acceso. Para conocer la corriente cerca del canal de acceso emplean una embarcación menor, dejándola derivar para determinar la corriente, ya que no se dispone de más información ni elementos de medida de la corriente, que se han solicitado en numerosas ocasiones.

En nuestro caso, la corriente de referencia en mar abierto (zona de morros en las escolleras del canal de acceso) es paralela a la costa, de componentes ESE y WNW que no penetra en el canal de acceso. Como velocidad de corriente superficial de referencia se considera 2 nudos en ambos casos.

En el interior de la laguna puede verse afectado por corrientes locales, debidas principalmente al flujo y reflujo de la marea entre los distintos vasos. En concreto, en la zona de estudio, y en épocas de lluvias, se produce una importante corriente de desagüe del Vaso III al Vaso II que se presenta en la zona de maniobra de la dársena de ciaboga No. I. Para la corriente en el interior de la Laguna de Cuyutlán se considera una corriente de 0.50 nudos, asociada al flujo y reflujo de la marea.

La definición geométrica de las Áreas de Navegación y Flotación está basada en el conocimiento de los espacios ocupados por los buques, que dependen de:

- El propio buque y los factores que afectan a sus movimientos.
- El nivel de las aguas y los factores que afectan a su variabilidad.

Para que la navegación se efectúe en condiciones de seguridad, estos espacios ocupados por el buque deberán tener cabida suficiente dentro de los espacios físicos disponibles en el

emplazamiento, para lo cual será necesario tomar en consideración los factores de incertidumbre relacionados con el contorno (suelo, paramentos, otros buques navegando o en flotación, elementos que afecten a los gálibos aéreos, etc.). Con objeto de mantener un adecuado margen de seguridad, se precisa disponer de unos espacios adicionales entre los requeridos por los buques y los disponibles según las condiciones de contorno del emplazamiento.

Para la valoración de los resguardos de seguridad se toma en consideración los diferentes supuestos de riesgo que pueden presentarse atendiendo a la siguiente tipología de modos de fallo o estados límite últimos:

- Colisión entre embarcaciones en navegación.
- Colisión de una embarcación en navegación con un objeto flotante (embarcación fondeada o amarrada, boya, etc.).
- Impacto de un buque con un objeto fijo rígido (muelle, pila o tablero de un puente, etc.).
- Contacto de un buque con el fondo o taludes del suelo, tomando en cuenta la naturaleza de éste, así como la posibilidad de que se produzca una varada.

3.4.1 Determinación de Profundidades de Agua de Las Áreas de Navegación

Para la determinación de la profundidad de agua necesaria en las diferentes áreas de navegación (canal de acceso, dársenas de ciaboga, dársena de muelle y canales interiores), se realizó en cada caso tomando en consideración los factores siguientes:

- El calado de los buques y los factores relacionados con los barcos que puedan ocasionar que algún punto de su casco alcance una cota más baja que la correspondiente a quilla plana en condiciones estáticas en agua de mar.

- El nivel del agua que se considere y los factores que afectan a su variabilidad, que determinarán el plano de referencia para emplazar el buque.

- Los márgenes de seguridad que se establezcan para prevenir un contacto del buque con el fondo.

En general el análisis se efectuó suponiendo que los buques de diseño operarán a plena carga. Asimismo, se fijaron las condiciones climatológicas (mareas, vientos, oleajes, etc.) y de seguridad y ayudas a la navegación (resguardos, remolcadores, etc.), que permitiesen efectuar las operaciones requeridas en la ampliación del puerto en el interior de la Laguna de Cuyutlán.

3.4.2 Determinación de la Configuración y Dimensiones de las Áreas de Navegación.

La determinación de la configuración y dimensiones en planta necesarias en las diferentes áreas de navegación en el interior de la Laguna de Cuyutlán se tomó en cuenta las áreas planteadas en la planeación de la ampliación del puerto de Manzanillo en dicha laguna, para lo cual se realizó una revisión en cada caso tomando en consideración los factores siguientes:

- El tamaño, dimensiones y características de maniobrabilidad de los buques de diseño y los factores relacionados con los barcos, incluida la disponibilidad de remolcadores, de los que depende la superficie necesaria para la realización de la navegación, maniobras o permanencia de los buques en el área que se considere (canal de acceso, dársenas de ciaboga, dársena de muelle y canales interiores).

- Las ayudas a la navegación disponibles y los factores que afectan a su exactitud y fiabilidad, que determinarán las líneas o puntos de referencia para emplazar el buque.

- Los márgenes de seguridad que se establezcan para prevenir un contacto del buque con los contornos de las áreas de navegación o flotación (a pie de muelle), o con otras embarcaciones u objetos fijos o flotantes que puedan existir en el entorno.

La consideración de los factores anteriores permite determinar la superficie y dimensiones mínimas requeridas en planta, o dimensiones nominales, que deberán ser exigidas a las profundidades nominales de agua en función de los buques de diseño.

3.4.3 Bocana del Canal de Acceso

La boca de entrada y salida de la Laguna de Cuyutlán se proyectó tomando en consideración los siguientes condicionantes principales:

- La configuración general de la ampliación del puerto y su integración con la infraestructura futura (muelles, dragados, etc.) y en sus áreas de flotación (canales de navegación, áreas de maniobras de buques, dársenas, etc.), así como la morfología y tipología estructural de los elementos que configuran la bocana.

- La navegación de entrada y salida de los buques a la ampliación del puerto, contemplando tanto las intensidades de tráfico previsibles, como los mayores buques de diseño que se prevea operen en el puerto, en las condiciones límites de operación que se establezcan.

- La limitación a la entrada de energía del oleaje en el interior de la ampliación del puerto, atendiendo al clima marítimo existente en el emplazamiento, de manera que la agitación que se produzca en las áreas de flotación utilizadas por el puerto sea la menor posible, en función de los usos que se prevea desarrollar en cada una de ellas.

- La conveniencia de limitar los períodos de cierre del puerto que se generen en la propia bocana, ocasionados por el clima marítimo existente en la zona y la configuración que se adopte para la bocana (rotura del oleaje en la boca del puerto, generación de fuertes corrientes transversales, etc.).

- La dinámica litoral existente en la zona y las modificaciones que se puedan producir en ella a consecuencia de las propias infraestructuras portuarias, tomando en consideración no sólo las afecciones que puedan producirse en el propio puerto (aterramientos de la bocana y de otras áreas de navegación), sino también los que se pudieran ocasionar en otras zonas próximas o remotas afectadas por la misma dinámica litoral.

- Las características geológicas y geotécnicas en la zona de desarrollo y la idoneidad consecuente de los terrenos para recibir obras de infraestructuras o desarrollar sobre ellos áreas de flotación.

- Las previsibles ampliaciones del puerto y las limitaciones que a este respecto pudiera representar la configuración que se adopte para la bocana.

- Los impactos medioambientales que puedan producirse tanto en fase de construcción como en fase de servicio, etc.

- La incidencia de otros condicionantes de planificación diferentes estrictamente portuario, que pudieran afectar al desarrollo portuario en concreto que se analice, y en particular los que se deriven del planeamiento urbano y costero.

En la práctica, la consideración de todos estos condicionantes conducirá a soluciones en las que se consiga un equilibrio entre condicionantes que a veces resultarán contrapuestos (por ejemplo, la obtención de la mejor accesibilidad podría conllevar unos índices de agitación en el interior del puerto poco adecuados para el futuro desarrollo portuario en la Laguna de Cuyutlán).

3.4.4 Áreas de Maniobra

Cuando un barco se aproxima a un puerto o a una terminal, ya sea navegando desde el mar abierto o por una vía de navegación, debe hacerlo a una velocidad mínima suficiente para mantener la navegación controlada en función de las características del emplazamiento y de las condiciones climáticas existentes. Antes de que el buque efectúe las maniobras de atraque debe poder reducir su velocidad prácticamente a cero, necesitando un espacio suficiente para que esta parada del buque pueda desarrollarse en condiciones de seguridad. Por otra parte, y simultánea o posteriormente a la operación anterior, es necesario en un gran número de casos que el buque

cambie su orientación, girando en espacios reducidos para adecuarse a la alineación requerida por el muelle o atraque que vaya a ocupar.

El proceso es similar en las maniobras de salida, pudiendo requerirse reviro de buques y aceleración de su movimiento para alcanzar las condiciones necesarias de navegación para abandonar el puerto en condiciones de seguridad. Los espacios necesarios para esta doble función de parada (o aceleración) y reviro del buque se engloban dentro del concepto de áreas de maniobra, ya que frecuentemente son operaciones interconectadas y que en ocasiones pueden desarrollarse en un mismo espacio

El dimensionamiento de las áreas de maniobra depende fundamentalmente de los aspectos siguientes:

- El tamaño, dimensiones y características de los buques más desfavorables que se prevé recibir (que pudieran no ser los mayores, por lo que habitualmente se precisará analizar diversos tipos de buques).

- El volumen y naturaleza del tráfico, así como las velocidades admisibles de navegación con que los buques acceden a estas áreas.

- Las características geométricas de los espacios en los que deben desarrollarse estas maniobras.

- El clima marítimo existente en la zona y en particular las condiciones límites de operación que se establezcan para la realización de las maniobras.

- Los efectos de caída lateral de la popa que se producen en las fases finales de la maniobra y que son más acusados en los buques de formas llenas, a bajas velocidades, y más acentuados cuanto más elevada es la profundidad de agua y cuanto mayor es el régimen de máquina atrás utilizado en la maniobra.

- La disponibilidad de remolcadores y las características de estos para la realización de las diferentes operaciones asociadas a la maniobra.

En el análisis realizado, se parte del hecho que no se efectúan maniobras de dos o más buques simultáneamente, por lo que las dimensiones que se establecen están basadas en los espacios requeridos para un solo buque.

3.4.5 Canales de Navegación.

El proyecto de un canal de navegación depende principalmente de los siguientes factores:

- El tamaño, dimensiones y características de maniobrabilidad de los buques más desfavorables que se prevé recibir (que pudieran no ser los mayores, por lo que habitualmente se precisará analizar diversos tipos de buques); en el supuesto de que el estudio se realice considerando la flota subdividida en tramos se considerará el más desfavorable de cada tramo.

- El volumen y naturaleza del tráfico, así como las velocidades admisibles de navegación.

- El tipo de navegación que se prevea realizar, en función del número de vías de circulación disponibles.

- Las características geométricas de la alineación de la vía navegable y las condiciones del entorno en que se encuentre situada.

- El tipo de las ayudas a la navegación, así como sus características de exactitud y disponibilidad.

- La profundidad y características geométricas transversales de la vía navegable.

- La estabilidad de los taludes de la vía navegable.

- Las condiciones climáticas marítimas y meteorológicas existentes en la zona, especialmente la naturaleza e intensidad de las corrientes transversales y muy destacadamente la variación de estas corrientes a lo largo del eje de la vía navegable.

- La experiencia de los pilotos de puerto.

Para la revisión de las áreas de navegación se partirá de la traza definida de las áreas de navegación, determinándose a continuación la anchura requerida en todas sus secciones críticas, para establecer posteriormente las transiciones de anchura entre los diferentes tramos. El procedimiento será iterativo en la medida en que la consideración de los diferentes factores obligue a reconsiderar alguno de los parámetros iniciales de diseño.

Aunque la revisión del trazado en planta de las áreas de navegación depende en gran medida de la definición de las condiciones locales, se han seguido las siguientes recomendaciones generales para la dicha revisión del diseño:

- El canal de navegación debe ser lo más recto posible, evitando trazados en S (curva seguida de contracurva).

- El canal de navegación deberá seguir, si es factible, la dirección de las corrientes principales, de manera que se minimice el efecto de las corrientes transversales. Este criterio también deberá seguirse con vientos y oleajes, si bien será más difícil de conseguir dado que normalmente provendrán de diversas direcciones. Asimismo, se debe evitar las áreas de depósito de sedimentos, para minimizar los costos de mantenimiento.

- El canal de navegación de aproximación se orientará si es factible, de manera que se eviten los temporales de través, es decir, orientándolas preferentemente en la dirección del oleaje reinante o cuanto más formando ángulo de hasta 15/20° entre eje de la vía de navegación y la dirección de estos oleajes reinantes.

- El canal de navegación de aproximación a la bocana de la laguna debe ser preferentemente recto evitando curvas en o próximas a la entrada, de manera que se evite la necesidad de que los buques tengan que efectuar correcciones de rumbo en una zona difícil y crítica para la navegación.

- El trazado de los canales de navegación tratará de evitar que los barcos tengan que efectuar la aproximación a muelles y atraques transversalmente a ellos, lo que podría producir un accidente en caso de pérdida de control del buque. De ser posible el canal de navegación deberá quedar situado paralelo a muelles y atraques para que esta maniobra se efectúe con mínimo riesgo. Esta precaución se extremará en caso de tratarse de tráfico de mercancías peligrosas.

- El paso de secciones estrechas (puentes, bocanas, etc.) se efectuará en tramos rectos bien balizados de la vía navegable, manteniendo la alineación recta en una distancia mínima de 5 esloras del buque máximo, a uno y otro lado de la sección estrecha.

- En caso de precisarse curvas es mejor una sola curva que una secuencia de pequeñas curvas a cortos intervalos, siempre y cuando la vía navegable esté correctamente balizada.

- El radio de las curvas será como mínimo de 5 esloras del buque de mayores dimensiones que se prevé utilizará la vía navegable, utilizándose preferiblemente radios de 10 esloras o más si es factible; los valores mayores se utilizarán cuanto más grande sea el ángulo entre las alineaciones rectas que definen la curva.

- La longitud de los tramos curvos no debe ser mayor que la mitad del radio de la curva, lo que significa que el ángulo entre alineaciones rectas no debe ser superior a 30°, si es factible.

- La distancia de visibilidad medida en el eje de la vía de navegación debe ser superior a la distancia de parada del buque de diseño suponiendo que navega a la velocidad máxima de navegación admisible en la vía.

- Las transiciones entre tramos de diferente anchura se efectuarán ajustando las líneas límites o de limitación mediante alineaciones rectas con variaciones en planta no mayores de 1:10 (preferentemente 1:20) en cada una de ellas.

3.4.6 Dimensionamiento de las Áreas de Navegación

De acuerdo con el análisis desarrollado para el dimensionamiento de las áreas de navegación se obtuvieron los resultados mostrados en la Tabla 3.4.

Tabla 3.4 Resumen de Resultados de Dimensiones de Áreas de Navegación.

Buque de Diseño				Ancho de Plantilla de Canal			Dársenas			
Tipo	Eslora (m)	Manga (m)	Calado (m)	Bocana (m)	Acceso (m)	Interno (m)	Ciaboga			Operativa en Muelles (m)

Fuente: Elaboración propia, 2026.

La propuesta original planteada para el desarrollo portuario considera la ampliación de la plantilla del canal de acceso de 250 a 300 m de ancho y en el interior los canales de navegación. Considerando el análisis realizado, se tiene que para una embarcación de 400 m de eslora y una manga de 62 m y bajo las condiciones físicas existentes en la zona de proyecto, el ancho de la plantilla en la bocana del canal de acceso se requiere sea de 316 m, que resulta mayor de los 250 m que actualmente tiene, asimismo, el ancho de plantilla requerido en el resto del canal de acceso es de 224 m que resulta ser menor al existente. Por otra parte, para el caso de los canales interiores, el ancho de la plantilla de acceso se ha definido de 200 m siendo similar a lo planteado en el anteproyecto original.

Considerando lo anterior, se recomienda que el ancho de la plantilla del canal de acceso en la zona entre morros de la escollera se amplie a 316 m en una longitud de 270 m, posteriormente se tendría una transición para pasar de 316 m de ancho a 250 m, esta transición

tendría una longitud de 450 m. El resto de la plantilla del canal de acceso sería de 250 m y con una longitud de 917.82 m, con lo cual, el canal de acceso tendría una longitud total de 1,637.82 m.

Por lo que respecta a las dársenas de ciaboga, el anteproyecto original contempla tres dársenas de ciaboga con diámetros de 600 m y 800 m. Considerando el análisis realizado y como se ha comentado anteriormente, la dársena existente o la dársena de ciaboga No. 1, mantiene su diámetro de 600 m de eslora para una primera etapa, ya que esta solo será utilizada por los buques gaseros de la empresa KMS y por los buquetanques de la empresa LFG. La dársena de ciaboga No. 2, que se localiza hacia el norte del canal de acceso, tendrá un diámetro de 800 m, la cual estará conectada con el canal de acceso por un canal de navegación de 250 m de ancho y con el canal interior de navegación Norte, el cual tendrá un ancho de 200 m.

La dársena de ciaboga No. 3, que se localiza en la zona noroeste del Vaso II de la laguna de Cuyutlán, el anteproyecto de planeación original contempla una dársena de ciaboga de 600 m de diámetro, sin embargo, considerando el análisis desarrollado esta dársena se propone con un diámetro de 800 m, similar a la dársena No. 2, lo anterior se fundamenta que esta zona en particular de la laguna, durante marea baja queda expuesto el fondo marino, lo anterior implica que la única zona profundizada sería la dársena de ciaboga y con las paredes a una distancia corta de la embarcación (100 m aproximadamente) podrían presentarse problemas de succión de la embarcación hacia las paredes de la dársena, asimismo, la visión que se tendría desde el puente de mando del buque sería deficiente por la altura del puente de mando con respecto a las orillas de la dársena.

Por último, los canales de navegación interna, se tendrá un canal localizado hacia el norte de la Laguna (canal de navegación norte), paralelo a los muelles de las terminales especializadas de contenedores, con un ancho de plantilla de 200 m, el cual conectará la dársena de ciaboga No 2 con la dársena de ciaboga No. 3. El segundo canal se localizará al sur de las islas cocodrilo (canal de navegación su), contará con un ancho de 200 m y conectará la dársena de ciaboga No. 3 con la dársena de ciaboga No. 2. En una primera etapa, el canal principal de navegación interna será el canal norte, esto es, que será este canal el que se use para entrar y salir del puerto, quedando el canal sur como un canal reservado para las embarcaciones de la Secretaría de Marina. Para una segunda etapa, el canal norte será utilizado solo de entrada, desde la bocana hasta la dársena de ciaboga No. 3 y el canal sur exclusivamente de salida, esto es, desde la dársena de ciaboga No. 3, hasta la bocana, lo anterior busca reducir los tiempos de maniobra de entradas y salidas del futuro puerto.

Las profundidades de dragado de las áreas de navegación definidas anteriormente se realizó el análisis correspondiente cuyos resultados se muestran en la Tabla 3.5. En la primera etapa de desarrollo, la profundidad de la bocana en el canal de acceso se tendrá una profundidad de -19.00 m y en el resto de las áreas de navegación interna se tendrá una profundidad de -18.00 m, solo en el canal de navegación sur la profundidad será de -10.00 m. Para la segunda etapa, la

bocana tendrá una profundidad de -22.50 m y el resto de las áreas de navegación se profundizará a -21.00 m, incluyendo el canal de navegación sur.

Tabla 3.5 Resumen de Resultados de Análisis de Profundidad de Áreas de Navegación.

Buque de Diseño				Profundidad en Plantilla de Canales			Dársenas

Fuente: Elaboración propia, 2026.

Todas las profundidades están referidas al Nivel de Bajamar Media Inferior (NBMI).

En resumen, las áreas de navegación quedan definidas de la siguiente forma:

I. Primera Etapa.

a. Canal de Acceso:

1. Bocana:

- Ancho: 316 m
- Largo: 270 m
- Profundidad de dragado: -19.00 m
- Talud de dragado: 4:1 (H:V)

2. Canal de Acceso Transición:

- Ancho: 316 m a 250 m
- Largo: 450 m
- Profundidad de dragado: de -19.00 m a -18.00 m
- Talud de dragado: 4:1 (H:V)

3. Canal de Acceso:

- Ancho: 250 m
- Largo: 917.82 m
- Profundidad de dragado: -18.00 m

- Talud de dragado: 4:1 (H:V)

La longitud total del canal de acceso es 1,637.82 m

b. Canal Interior:

1. Zona entre Dársenas 1 y 2:

- Ancho: 250 m
- Largo: 1,932.95 m
  - Curva No. 1:
    - Ancho: 250 m
    - Largo: 519.58 m
    - Radio: 800 m
  - Tramo Recto:
    - Ancho: 250 m
    - Largo: 1,153.10 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 260.27 m
    - Radio: 1,200 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

2. Zona entre Dársenas 2 y 3 (Canal Norte):

- Ancho: 200 m
- Largo: 4,178.58 m
  - Curva No. 1:
    - Ancho: 200 m
    - Largo: 652.00 m
    - Radio: 1,200 m
  - Curva No. 2:
    - Ancho: 200 m
    - Largo: 1,134.68 m
    - Radio: 1,200 m
  - Tramo Recto No. 1:
    - Ancho: 200 m
    - Largo: 1,561.96 m
  - Tramo Recto No. 2:
    - Ancho: 200 m
    - Largo: 829.94 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) arenas y 6:1 (H:V) arcillas

c. Canal Sur:

1. Zona entre Dársenas 3 y 2:

- Ancho: 200 m
- Largo: 3,983.25 m
  - Tramo Recto No. 1:
    - Ancho: 200 m
    - Largo: 1,032.77 m
  - Curva No. 1:
    - Ancho: 200 m
    - Largo: 399.14 m
    - Radio: 1,100 m
  - Tramo Recto No. 2:
    - Ancho: 200 m
    - Largo: 1,355.24 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 210.63 m
    - Radio: 1,100 m
  - Tramo Recto No. 3:
    - Ancho: 200 m
    - Largo: 985.47 m
- Profundidad de dragado: -10.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

Las tres dársenas de ciaboga presentan las siguientes características:

d. Dársena de Ciaboga No. 1:

- Diámetro: 600 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

e. Dársena de Ciaboga No. 2:

- Diámetro: 800 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

f. Dársena de Ciaboga No. 3:

- Diámetro: 800 m
- Profundidad de dragado: -18.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

II. Segunda Etapa.

a. Canal de Acceso:

1. Bocana:

- Ancho: 316 m
- Largo: 270 m
- Profundidad de dragado: -22.50 m
- Talud de dragado: 4:1 (H:V)

2. Canal de Acceso Transición:

- Ancho: 316 m a 250 m
- Largo: 450 m
- Profundidad de dragado: de -22.50 m a -21.00 m
- Talud de dragado: 4:1 (H:V)

3. Canal de Acceso:

- Ancho: 250 m
- Largo: 917.82 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 4:1 (H:V)

La longitud total del canal de acceso es 1,637.82 m

b. Canal Interior:

1. Zona entre Dársenas 1 y 2:

- Ancho: 250 m
- Largo: 1,932.95 m
  - Curva No. 1:
    - Ancho: 250 m
    - Largo: 519.58 m
    - Radio: 800 m
  - Tramo Recto:
    - Ancho: 250 m
    - Largo: 1,153.10 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 260.27 m
    - Radio: 1,200 m
- Profundidad de dragado: -21.00 m

- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

2. Zona entre Dársenas 2 y 3 (Canal Norte):

- Ancho: 200 m
- Largo: 4,178.58 m
  - Curva No. 1:
    - Ancho: 200 m
    - Largo: 652.00 m
    - Radio: 1,200 m
  - Curva No. 2:
    - Ancho: 200 m
    - Largo: 1,134.68 m
    - Radio: 1,200 m
  - Tramo Recto No. 1:
    - Ancho: 200 m
    - Largo: 1,561.96 m
  - Tramo Recto No. 2:
    - Ancho: 200 m
    - Largo: 829.94 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) arenas y 6:1 (H:V) arcillas

c. Canal Sur:

1. Zona entre Dársenas 3 y 2:

- Ancho: 200 m
- Largo: 3,983.25 m
  - Tramo Recto No. 1:
    - Ancho: 200 m
    - Largo: 1,032.77 m
  - Curva No. 1:
    - Ancho: 200 m
    - Largo: 399.14 m
    - Radio: 1,100 m
  - Tramo Recto No. 2:
    - Ancho: 200 m
    - Largo: 1,355.24 m
  - Curva No. 2:
    - Ancho: 250 m
    - Largo: 210.63 m
    - Radio: 1,100 m
  - Tramo Recto No. 3:

  - Ancho: 200 m
  - Largo: 985.47 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

Las tres dársenas de ciaboga presentan las siguientes características:

d. Dársena de Ciaboga No. 1:

- Diámetro: 600 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

e. Dársena de Ciaboga No. 2:

- Diámetro: 800 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

f. Dársena de Ciaboga No. 3:

- Diámetro: 800 m
- Profundidad de dragado: -21.00 m
- Talud de dragado: 3:1 (H:V) y 6:1 (H:V) arcillas

La superficie total navegable o de las zonas de navegación interior de la Laguna de Cuyutlán es de 372.35 ha[6].

3.5 Volúmenes de Dragado y Relleno.

3.5.1 Volumen de Dragado.

Considerando las áreas de navegación definidas anteriormente y el buque de diseño, se definieron las profundidades para que los buques puedan realizar las operaciones de entrada, atraque y salida de la Laguna de Cuyutlán.

El volumen de dragado para la primera etapa se divide de acuerdo con el material a extraer (arcillas, arenas y roca). En el caso de las arcillas el volumen a extraer es de 38.30 millones de metros cúbicos, es importante recordar que de acuerdo con mecánica de suelos este tipo de material no es apto para rellenos, por lo que este deberá ser retirado de la zona de proyecto.

[6] La supercie no incluye la zona dragada de localización de las plataformas.

Las arenas por dragar representan un volumen de 45.25 millones de metros cúbicos en la primera etapa, este material será el que se use para los rellenos en la zona destinada para las terminales especializadas de contenedores I y II, así como la zona destinada a la terminal de PEMEX.

El volumen total por dragar en la primera etapa entre arcillas y arenas en la zona de proyecto es de 83.55 millones de metros cúbicos.

Con respecto a la extracción de roca, esta se localiza principalmente en la zona del canal de acceso contiguo a la escollera este, cuyo volumen es de 18.21 mil metros cúbicos.

3.5.2 Volumen de Relleno.

El volumen de arena que se requiere para alcanzar la cota de +4.50 m en la zona de plataformas de las TEC I y II, así como en la terminal de PEMEX, es de 18.28 millones de metros cúbicos, de los cuales el 97% del total corresponde a la zona de plataformas para las terminales de contenedores (17.73 millones de metros cúbicos) el restante 3% corresponde a la zona destinada a las instalaciones de PEMEX (0.55 millones de metros cúbicos).

La diferencia entre el volumen de material de dragado y el material para relleno es de 26.97 millones de metros cúbicos.

Por otra parte, y de acuerdo con el análisis desarrollado, el volumen de dragado considerando únicamente el dragado las áreas de agua necesarias para la operación de la TEC I (del cadenamiento 0+000 al 5+100), así como los rellenos correspondientes a esa terminal y a la de PEMEX, es de 19.74 millones de metros cúbicos y el relleno es de 11.05 millones de metros cúbicos, teniendo una diferencia de 8.69 millones de metros cúbicos de material sobrante.

Si se busca una compensación entre el volumen de dragado y el de relleno, se tendría que dragar a una profundidad de -16 m, con lo cual se tiene un volumen de dragado de 14.68 millones de metros cúbicos teniendo una diferencia de 3.63 millones de metros cúbicos de material de dragado. Sin embargo, se debe revisar la respuesta de maniobra de las embarcaciones con esta condición de profundidad en las áreas de navegación.

Es recomendable que este volumen remanente sea almacenado para su posterior utilización en la construcción de la TEC II y en la segunda etapa de desarrollo de la ampliación del puerto de Manzanillo en el interior de la Laguna de Cuyutlán.

4.0 CONCLUSIONES Y RECOMENDACIONES.

4.1 Conclusiones.

- El análisis técnico desarrollado permite establecer que el diseño de las áreas de navegación en la Laguna de Cuyutlán responde de manera adecuada a los requerimientos operativos del puerto, considerando las dimensiones y características del buque de diseño, así como las condiciones hidrodinámicas predominantes en la zona.

- Las condiciones geotécnicas del sitio, caracterizadas por la presencia de materiales arcillosos superficiales, arenas medianamente compactas y estratos altamente densos, influyen de manera significativa en la definición de los métodos de dragado, los taludes de excavación y el aprovechamiento de los materiales. En este contexto, se identifica que los materiales arcillosos no son aptos para relleno, mientras que los materiales arenosos representan una fuente viable para la conformación de plataformas portuarias.

- El dimensionamiento de canales, dársenas y áreas de maniobra garantiza condiciones seguras de navegación, incorporando márgenes adecuados para maniobras, efectos ambientales y posibles incertidumbres operativas.

- En términos volumétricos, el proyecto presenta un volumen significativo de material dragado, con un excedente respecto a las necesidades de relleno, lo que implica la necesidad de una adecuada estrategia de disposición o aprovechamiento en etapas futuras del desarrollo portuario.

- En conjunto, el proyecto de dragado establece bases técnicas sólidas para la habilitación de la infraestructura marítima requerida, asegurando la funcionalidad operativa y la seguridad de las maniobras portuarias.

4.2 Recomendaciones.

- Implementar un programa de monitoreo batimétrico continuo durante la ejecución del dragado para verificar el cumplimiento de profundidades y geometrías de diseño.

- Evaluar el uso del material excedente en futuras etapas del desarrollo portuario, con el fin de mejorar la eficiencia económica del proyecto.

- Revisar periódicamente las condiciones de sedimentación en las áreas dragadas, a fin de establecer estrategias de mantenimiento preventivo.

- Validar mediante simulaciones de maniobra o análisis operativos el desempeño de las áreas de navegación diseñadas, especialmente para buques de gran escala.

1.0 INTRODUCCIÓN

El desarrollo y ampliación de infraestructura portuaria constituye un elemento estratégico para fortalecer la competitividad logística y comercial del país. En este contexto, el Proyecto Arquitectónico de Redimensionamiento, Actualización, Adecuación y Optimización Conceptual de la Infraestructura y Equipamiento del Puerto Nuevo Manzanillo–Cuyutlán tiene como propósito atender el crecimiento sostenido del comercio marítimo internacional y consolidar al puerto de Manzanillo como el principal nodo portuario del sistema marítimo nacional.

La expansión hacia la Laguna de Cuyutlán implica la ejecución de obras de infraestructura marítima de gran escala, entre las que destacan los trabajos de dragado, conformación de rellenos hidráulicos y la construcción de estructuras de contención mediante muros de tablestacado metálico. Estas obras requieren una planificación técnica detallada debido a las condiciones particulares del sitio, caracterizadas por la presencia de sedimentos arcillosos, arenas compactas y posibles afloramientos de roca, así como por la interacción de procesos hidrodinámicos, mareales y sedimentológicos propios de un sistema lagunar.

El presente informe parcial tiene como finalidad describir el procedimiento constructivo propuesto para las principales actividades asociadas a la ampliación del puerto, incluyendo los trabajos de dragado, conformación de rellenos, mejoramiento del terreno y la construcción de estructuras de contención mediante tablestacas metálicas tipo HZ y AZ. Asimismo, se detallan los criterios técnicos para la selección de equipos, la organización de los trabajos y las medidas constructivas necesarias para garantizar la estabilidad estructural, la eficiencia operativa y la seguridad durante la ejecución de las obras.

La correcta integración de estas actividades resulta fundamental para asegurar la viabilidad técnica del proyecto, optimizar el aprovechamiento de los materiales producto del dragado y garantizar el adecuado comportamiento geotécnico y estructural de las futuras explanadas y terminales portuarias que formarán parte del desarrollo del Puerto Nuevo Manzanillo–Cuyutlán..

2.0 OBJETIVOS.

2.1 Objetivo Principal.

El objetivo principal de los servicios descritos en el presente documento es:

- Definir, estructurar y justificar integralmente el procedimiento constructivo para la ejecución de las obras asociadas a la ampliación del Puerto Nuevo Manzanillo–Cuyutlán en la Laguna de Cuyutlán, considerando la interacción entre dragado, conformación de rellenos, mejoramiento del terreno y construcción de estructuras de contención, con el propósito de garantizar la viabilidad técnica, la estabilidad geotécnica, la eficiencia operativa y la correcta integración funcional de la infraestructura portuaria dentro de un sistema constructivo coordinado y ejecutable en condiciones lagunares complejas.

2.2 Objetivos Particulares.

Los objetivos particulares de los servicios descritos en el presente documento son:

- Establecer criterios técnicos integrales para la selección, dimensionamiento y operación del equipo de dragado, en función de las características geotécnicas de los materiales, las condiciones hidráulicas y los requerimientos de producción del proyecto.

- Definir la secuencia constructiva del dragado, asegurando la correcta remoción de materiales no aptos y la recuperación eficiente de materiales aprovechables para relleno, optimizando tiempos y recursos dentro del programa de obra.

- Desarrollar el procedimiento constructivo de los rellenos hidráulicos, incorporando criterios de control sedimentológico, estabilidad, control de asentamientos y comportamiento a largo plazo de los materiales.

- Establecer estrategias de mejoramiento del terreno que permitan incrementar la capacidad portante y reducir deformaciones diferenciales, integrando técnicas como vibroflotación y control geotécnico continuo.

- Definir el procedimiento constructivo de las estructuras de contención mediante tablestacado metálico, incluyendo su integración con sistemas de anclaje, garantizando su estabilidad frente a empujes hidráulicos y de suelo.

- Establecer la lógica de integración entre los distintos sistemas constructivos (dragado, rellenos, contención, urbanización e infraestructura), asegurando su ejecución coordinada mediante frentes simultáneos de trabajo.

- Incorporar lineamientos para la planeación logística, organización de obra y operación de equipos en ambiente marino, considerando restricciones operativas, seguridad y eficiencia.

3.0 PROCESO CONSTRUCTIVO.

En el proceso constructivo para la ampliación del puerto de Manzanillo, no es posible hablar del dragado de profundización sin contemplar la construcción de las obras de contención de rellenos.

Es de suma importancia el considerar las condiciones físicas de la zona, principalmente lo relacionado con el tipo de suelo y las profundidades con las que cuenta actualmente la Laguna de Cuyutlán, ya que estos factores condicionan los equipos y el proceso de construcción. Como se ha comentado anteriormente, el suelo se constituye principalmente de dos capas, la primera de ellas se constituye de arcillas, el cual no es adecuado para ser utilizado como material en los rellenos de las explanadas que se requieren para el desarrollo de las terminales especializadas de contenedores y el área destinada a PEMEX. La segunda capa se constituye de arenas compactas.

Por tal motivo, las obras que se requieren ejecutar para la ampliación del puerto en la laguna se deben considerar de manera integral y que se complementan entre ellos.

3.1 Dragado y Conformación de Rellenos.

3.1.1 Selección del Equipo.

La elección del equipo de dragado y el método a utilizar no es una tarea sencilla, en gran medida el éxito de un proyecto de dragado depende de una buena elección. La selección de un equipo está en función de diferentes factores entre los más comunes tenemos; tenemos; el tipo de trabajo a realizar, la disponibilidad y ubicación del equipo, las dimensiones de la obra, la cantidad y naturaleza del material, la profundidad del dragado, los aspectos ambientales, y logística; estos y otros factores influyen en el costo del proyecto.

Actualmente, se cuenta con diversos tipos de dragas, cada uno tiene su particular forma de trabajar, cabe destacar que no existe ninguna draga estructurada que pueda realizar todos los rangos de dragado, por lo cual la elección dependerá de los factores antes mencionados.

Utilizar una técnica apropiada de dragado ayuda a optimizar los beneficios del proyecto, así como minimizar los impactos ambientales.

Para definir una técnica de dragado se debe conocer el tipo de sedimento, lo cual hace probable que éste sea en sedimentos cohesivos y no cohesivos, los sedimentos cohesivos se transportan a través de la tubería como grumos y nódulos, mientras que los sedimentos no cohesivos se dispersan en forma de suspensión, haciendo más fácil bombearlos a través de la tubería.

La variedad de equipos y métodos de dragado es muy extensa, dentro de la gran variedad de equipos de dragado, algunos se especializan en una de las tres fases de operación (excavación, transporte o vertido), pero otros son capaces de realizar todo el conjunto de la operación sin necesitar equipos o instalaciones auxiliares.

En la Tabla 3.1 se resumen las posibilidades de uso de los diferentes tipos de dragas, hidráulicas y mecánicas, tomado de lo expresado por el Prof. Wim Vlasblom[1].

Tabla 3.1 Uso de Diferentes Tipos de Draga.

Concepto	Draga de cangilones (bucketladder)	Draga de grúa (grab dreger)	Draga de cucharón (backhoe)	Draga de succión	Draga de succión con cortador	Draga autopropulsada de tolva (hooper)
Dragado material arenoso	SI	SI	SI	SI	SI	SI
Dragado material arcilloso	SI	SI	SI	NO	SI	NO
Dragado material rocoso	SI	NO	SI	NO	SI	NO
Cables para anclaje	SI	SI	NO	SI	SI	SI
Máxima profundidad de dragado	30 m	>100 m	20 m	70 m	35 m	50 m
Posible precisión en dragado	SI	NO	SI	NO	SI	NO
Posible trabajar en mar abierto	NO	SI	NO	SI	NO	SI
Transporte vía tubería	NO	NO	NO	SI	SI	NO

Fuente: www.dredging.org., 2026

En base a las condiciones del material por remover y a las cualidades de trabajo de las dragas antes comentadas, se considera que la remoción de cada tipo de material identificado puede efectuarse como se señala en la Tabla 3.1.

Pensando en el material más resistente por remover, se puede finalmente recomendar el siguiente equipo:

- Draga hidráulica: se puede pensar en un equipo de succión provisto con cortador (DSC).

La draga de succión con cortador o draga de cortador es una draga que combina las ventajas de las dragas mecánicas y de las dragas hidráulicas, la disgregación del material se efectúa mediante el giro de un cabezal mecánico denominado cortador, esta gira y disgrega el material que es aspirado por succión a través de tuberías; la elevación y transporte se realiza por la succión generada en las bombas.

[1] Vlasblom, Wim, Lecture Notes on Dredging Equipment and Technology, April 2003 to May 2007, Central Dredging Association, www.dredging.org.

Las DSC pueden cortar prácticamente todo tipo de suelo, aunque esto depende de la potencia de corte instalada. Las DSC se presentan en una amplia variedad de tipos y tamaños; la potencia del cabezal de corte oscila entre 20 kW (la más pequeña) y 7,000 kW (la más grande). La profundidad de dragado suele ser limitada: la draga de succión más grande puede alcanzar profundidades de entre 25 y 35 metros. La profundidad mínima de dragado viene determinada por el calado de la pontona. La draga de succión con cortador es muy recomendable cuando ha de dragarse un perfil preciso.

Las DSC se presentan en diversos tamaños y tipos, desde una potencia del cortador de 20 kW (las dragas más pequeñas) hasta 30,000 kW (las más grandes). La profundidad de dragado depende del tamaño de la draga. Las más pequeñas pueden dragar a menos de 2 metros de profundidad, mientras que algunas de las dragas de succión con cortador más grandes pueden alcanzar profundidades de más de 35 metros. La profundidad mínima de dragado viene determinada por el calado de la pontona.

Tanto las DSC grandes como las pequeñas forman parte importante de las flotas de dragado de las principales empresas de dragado. Por ejemplo, las dragas medianas suelen tener una potencia en entre 10,000 y 15,000 kW, pero generalmente no están autopropulsadas. Recientemente, se han construido mega DSC, algunas de hasta 130 metros de eslora, y cuentan con una potencia total instalada de entre 24,000 y 28,200 kW. Algunas de estas DSC de vanguardia están accionadas por sistemas diésel - eléctricos. Éstas incorporan sistemas de alimentación ininterrumpida (SAI) para alimentar las computadoras y los equipos de navegación esenciales de la embarcación.

Con base en lo anterior, para los trabajos de dragado se ha seleccionado el equipo con las siguientes características:

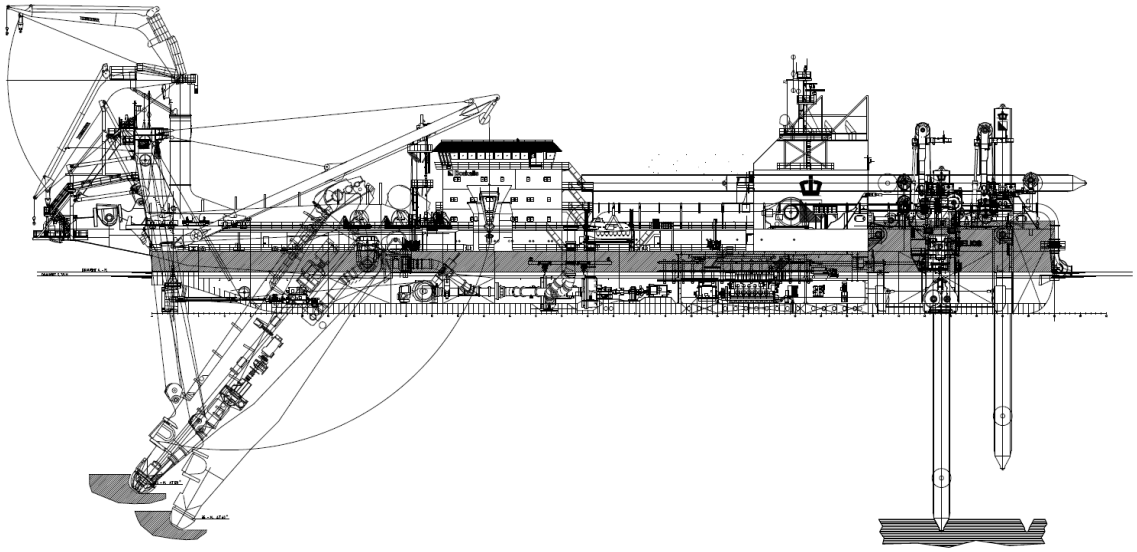
- Draga de succión con cortador: Draga autopropulsada de corte de alta resistencia para dragado a menos de 15 millas de la costa o a menos de 20 millas del puerto.
- Diámetro de la boca de succión: 1.00 m
- Máxima profundidad de dragado: -35.00 m
- Mínima profundidad de dragado: -6.35 m
- Potencia total instalada: 23,000 kW
- Máxima potencia de corte: 7,000 kW
- Potencia de bombeo total de 15,600 kW

Se considera que para la realización de los trabajos se utilicen por lo menos dos dragas con estas características, ver Figura 3.1.

De acuerdo con las características del fondo marino de la Laguna de Cuyutlán, el dragado deberá realizarse en dos etapas, la primera de ellas es el retiro de todo el material que no es

adecuado para su utilización como material de relleno en las plataformas que serán conformadas para las futuras terminales especializadas de contenedores y del área asignada a PEMEX.

Figura 3.1 Draga de Succión con Cortador de 23,000 kW.



Fuente: Base de datos de RHG Ingeniería.

Esta capa de arcilla presenta diferentes espesores, por lo que el dragado para llegar a las arenas tiene diferentes profundidades, siendo la mayor a -10.80 m y la menor queda ajusta a la profundidad operativa del equipo, siendo está a -6.35 m, ambas profundidades referidas al N.B.M.I.

Asimismo, la distancia de tiro se localiza fuera de la zona de la Laguna de Cuyutlán a una distancia aproximada de 2.00 MN (3.70 km) mar adentro, ver Figura 3.2, por lo que utilizar tuberías para el retiro de este material resulta una tarea complicada por los riesgos asociados con el bombeo a través de una tubería de aproximadamente 10 km de longitud pueden variar en función de diversos factores, incluidos el tipo de material transportado, el diseño y la integridad de la tubería, las condiciones del entorno circundante y las prácticas operativas empleadas, siendo los principales riesgos los siguientes:

a. Presión: El manejo inadecuado de la presión dentro del sistema de tuberías puede dar lugar a una sobrepresurización, lo que incrementa significativamente el riesgo de falla estructural, grietas o incluso rupturas de la tubería, sea esta flotante, terrestre o

sumergible. La sobrepresurización puede deberse a variaciones en el caudal de bombeo, golpes de ariete o bloqueos parciales dentro de la tubería.

Figura 3.2 Zona de Tiro.

Fuente: Elaboración propia, 2026

b. Fugas y Derrames: La integridad de la tubería puede verse comprometida por factores como corrosión, defectos en las juntas de empaque, daño mecánico o fallos en los materiales de construcción, lo que puede derivar en fugas y derrames de material transportado. Las fugas pueden representar un riesgo significativo para el medio ambiente, especialmente si la tubería atraviesa cuerpos de agua, áreas de conservación o zonas urbanas.

c. Bloqueos y Obstrucciones: La acumulación de sedimentos, residuos, basura, raíces u otros objetos dentro de la tubería puede generar obstrucciones parciales o totales, afectando el flujo y provocando aumentos de presión. En sistemas de bombeo de materiales abrasivos, como lodos o suspensiones con alto contenido de sólidos, la deposición de partículas puede acelerar la formación de bloqueos.

d. Corrosión y Erosión: Las tuberías pueden estar expuestas a procesos de degradación a lo largo del tiempo debido a la corrosión química (causada por la interacción con fluidos corrosivos) y la erosión mecánica (por la acción de partículas sólidas en movimiento). Estos efectos pueden debilitar las paredes del ducto y generar fallas estructurales progresivas.

e. Daño Mecánico Externo: Las tuberías que atraviesan zonas urbanas o áreas con actividad industrial están expuestas a posibles daños mecánicos causados por excavaciones, impactos accidentales de vehículos y/o maquinaria pesada o eventos naturales, como deslizamientos de tierra o actividad sísmica.

f. Variaciones de Temperatura y Efectos Termomecánicos: Las tuberías expuestas a condiciones climáticas extremas pueden sufrir dilatación o contracción térmica, lo que genera esfuerzos mecánicos adicionales que pueden comprometer la integridad estructural del sistema.

g. Riesgo por Errores Operacionales: Las fallas en la operación del proceso de dragado, como en el sistema de control de densidad durante el proceso de corte, el proceso de bombeo y la falta de control y monitoreo del transporte de la mezcla de material dragado desde la draga y durante el transporte durante toda la longitud de la tubería, así como, la manipulación inadecuada de válvulas, la falta de sincronización en el arranque y paro del bombeo mantenimiento deficiente, pueden comprometer la seguridad del sistema y aumentar la probabilidad de incidentes.

h. Impacto Ambiental y Regulaciones: El transporte de materiales a través de ductos en áreas ecológicamente sensibles requiere una gestión cuidadosa para evitar efectos adversos en el medio ambiente. Los derrames, fugas o filtraciones pueden contaminar suelos y cuerpos de agua, afectando la biodiversidad local y generando sanciones regulatorias.

Cualquiera de los riesgos previamente mencionados constituye un factor crítico que compromete la continuidad operativa del dragado y puede derivar en interrupciones prolongadas con consecuencias severas para el proyecto. La detección y localización de fallas en una tubería de 10 km (flotante, terrestre y/o sumergible) no solo requiere la suspensión inmediata de las actividades, sino que implica un proceso altamente complejo y tardado, ya que identificar el punto exacto de la avería en una infraestructura de esta magnitud es un desafío técnico significativo.

Además, la ejecución de reparaciones en estas condiciones, especialmente en entornos marinos adversos, no solo incrementa los riesgos operacionales para la tripulación y las embarcaciones de apoyo, sino que también añade incertidumbre en los tiempos de resolución. Estas interrupciones pueden desencadenar retrasos acumulativos que afectan la cadena completa de actividades, generando sobrecostos sustanciales debido a tiempos de inactividad, ajustes logísticos imprevistos y reprogramaciones forzadas que impactan directamente el cumplimiento del calendario global del proyecto.

Considerando lo anterior, para el dragado de la capa de arcilla se utilizará como equipo auxiliar a la draga de corte dos barcazas por draga (4 en total) con una capacidad mínima de 10,000 m^3 cada una (dimensiones aproximadas eslora: 134 m, manga: 26 m y calado: 7.8 m), ver Figura 3.3.

Figura 3.3 Barcaza de 10,000 m^3 de capacidad.

Fuente: Base de datos de RHG Ingeniería.

3.1.2 Organización de los Trabajos.

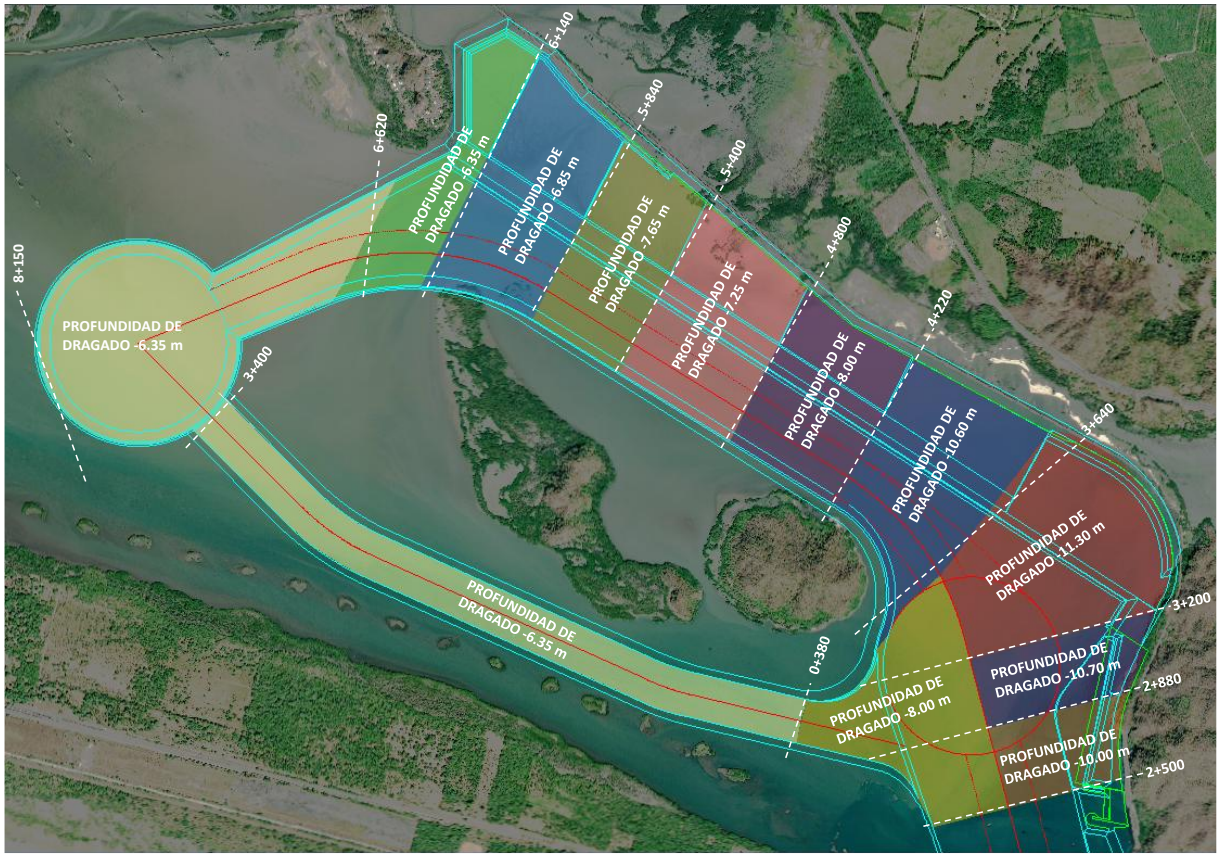
Los trabajos de dragado iniciaran aproximadamente en el cadenamiento 2+580, ver Figura 3.4, en dicho punto las dragas y las barcazas trabajaran en conjunto y coordinadamente para retirar la capa de arcilla de la siguiente manera:

- Cadenamiento 2+500 al 2+880 se dragará a una profundidad de -8.00 a -10.00 m.
- Cadenamiento 2+880 al 3+200 se dragará a una profundidad de -8.00 a -10.70 m.
- Cadenamiento 3+200 al 3+640 se dragará a una profundidad de -8.00 a -11.30 m.
- Cadenamiento 3+640 al 4+220 se dragará a una profundidad de -10.60 m.
- Cadenamiento 4+220 al 4+800 se dragará a una profundidad de -8.00 m.
- Cadenamiento 4+800 al 5+400 se dragará a una profundidad de -7.25 m.
- Cadenamiento 5+400 al 5+840 se dragará a una profundidad de -7.65 m.
- Cadenamiento 5+840 al 6+140 se dragará a una profundidad de -6.85 m.
- Cadenamiento 6+140 al 8+150 se dragará a una profundidad de -6.35 m.
- Canal sur, cadenamiento 0+380 al 3+400 se dragará a una profundidad de -6.35 m.

Es importante comentar que la profundidad mínima de -6.35 m corresponde al nivel de dragado mínimo que puede realizar la draga propuesta, por tal motivo, dependiendo del equipo

propuesto por la empresa responsable de ejecutar los dragados deberá verificar dicha profundidad, la cual puede ser menor o mayor dependiendo del calado de la draga y de la profundidad mínima a la que puede realizar el dragado.

Figura 3.4 Delimitación de Zonas y Profundidades a Dragar las Arcillas Primera Etapa.



Fuente: Elaboración propia, 2026

Una vez que se alcanzado el cadenamiento 4+740 (volumen de dragado aproximado de arcilla 10,156,200.35 m^3), una de las dragas tomará los trabajos de dragado y recuperación de las arenas para efectuar los rellenos y depositarlos entre los cadenamientos 3+660 al 4+740. Mientras que la segunda draga continuará con los trabajos de retiro de las arcillas con el apoyo de las cuatro barcazas.

Cabe resaltar dos aspectos importantes, el primero de ellos es que una vez que se inicien los trabajos de dragado de arenas se deberá inicial con la instalación del tablestacado, y el

segundo punto, es que probablemente se tenga que realizar trabajos de corte de roca en la margen Este del canal de acceso (estos puntos serán tratados en apartados independientes).

En el momento que la segunda draga haya terminado los trabajos de retiro de la arcilla, continuará los trabajos de dragado de la arena en apoyo a la primera draga. Dado que estos trabajos de dragado es recuperar el material extraído, este se realizará mediante tubería, por tal motivo, la utilización de las barcazas no será necesario para esta actividad por lo que se procederá a su retiro o reubicación en otras actividades.

3.1.3 Relleno.

Para los rellenos en las explanadas a través de tubería se observarán los aspectos detallados a continuación:

Cuando el relleno hidráulico llega al recinto a través de tubería se produce una disgregación del material, ya que los tamaños más gruesos se decantan en las proximidades de la boca de salida de la tubería y los más finos en las zonas con menor velocidad de la corriente. Por tanto, se asegurará que los materiales finos se depositan donde se haya previsto, pero nunca en el trasdós de las estructuras, como es el caso de la tablestaca, ni en aquellas zonas donde se comprometa la estabilidad estructural.

Cuando el caudal que aporta la draga es importante, no se sedimenta la totalidad de los sólidos. Para evitar que invadan zonas ya dragadas, se procederá de las siguientes formas:

- Instalando barreras de geotextil que retengan los sólidos en la zona de vertido.
- Cambiando el emplazamiento del aliviadero y/o modificando el recorrido de las aguas con movimientos del material de relleno.
- Recreciendo la altura de los cierres de los recintos después de asegurar la estabilidad de las motas de contención de los rellenos.
- Para rellenos de gran volumen en recintos de gran superficie puede ser conveniente construir éstos sectorizados (ver Figura 3.5), esto posibilita:
    - Utilizar algunos de los sectores como balsa para la decantación de los finos. La concentración en una zona de los finos facilita su posterior tratamiento.
    - Permite realizar la precarga por sectores.
    - Posibilita la puesta en servicio progresiva de los distintos sectores.

Teniendo en cuenta estas consideraciones se elaborará un Plan de Vertido que formará parte del Plan de Ejecución que incluirá:

- Estudio de sedimentaciones.

- Cálculo de estabilidad de las motas de cierre. En lugares con riesgo sísmico se debe prestar especial atención a la posibilidad de licuefacción del relleno y su consecuencia sobre la estabilidad de las motas.
- Barreras anticontaminantes.
- Estudio del abundamiento del material y de los asientos previstos, determinando las cotas en fase constructiva.

Figura 3.5 Recinto de Almacenamiento Sectorizado.

Fuente: Base de datos de RHG Ingeniería.

Como parte de los trabajos, se realizará el control geométrico del relleno mediante control topobatimétrico, dicha actividad tiene los siguientes objetivos:

- Controlar la situación de los rellenos en planta y en alzado.
- Conocer la evolución de los asientos a lo largo del tiempo.
- Realizar un seguimiento de la ubicación de los rellenos, tanto emergidos como sumergidos, y de sus posibles desplazamientos.

Para ello se procederá de la siguiente forma:

- Establecimiento de las bases de replanteo.
- Comprobación de la batimetría y la topografía iniciales.
- Controles batimétricos y topográficos periódicos.

- Implantación de testigos o instrumentación que permitan controlar los asientos en las distintas fases constructivas y una vez que los rellenos están terminados.
- Reconocimiento batimétrico de la zona de los yacimientos de los materiales.
- Proceso y archivo de los datos.

3.1.3.1 Mejoramiento del Terreno.

Los rellenos portuarios son altamente deformables y/o no tienen la capacidad de carga necesaria debido a la naturaleza de los materiales que conforman los fondos marinos y/o de los que sobre ellos se colocan.

Para limitar los asientos futuros y/o aumentar la capacidad portante del terreno existen diversos procedimientos de mejora:

- Sustitución del terreno.
- Precarga.
- Vibración profunda y columnas de grava.
- Compactación dinámica.
- Instalación de drenes.
- Inclusiones rígidas.
- Inyecciones y otros tipos de mejora.

La elección del procedimiento de mejora se debe realizar en función de los siguientes parámetros:

- La naturaleza del terreno que se pretende mejorar.
- La mejora que se pretende conseguir.
- El plazo temporal para la obtención de resultados.
- El costo de las distintas opciones.

Dado que en el proyecto del tablestacado se indica que se debe realizar un mejoramiento del terreno, en el trasdós de la pantalla principal y hasta cinco metros posteriores al eje de la tablestaca secundaria, se propone que el mejoramiento se realice mediante el método de vibroflotación, con el objetivo de no trasmitir al tablestacado esfuerzos adicionales a su diseño o que esta resulte dañada en el proceso constructivo de mejoramiento.

La vibración profunda es una técnica que mejora los terrenos por la acción de una vibración enérgica; esta técnica se aplica con éxito en terrenos granulares flojos. La vibración transmitida al terreno provoca la inestabilidad de su estructura, induciendo una licuefacción parcial y provocando asientos en superficie.

Se realiza con vibradores de gran tamaño -con peso entre 20 y 40 kN y con diámetros entre 20 y 50 cm- y se pueden tratar terrenos arenosos hasta profundidades de 15 m.

El radio de acción de la vibración depende de la potencia del equipo y del tipo de terreno. En la práctica usual, se suele hacer el tratamiento con una columna de vibrado por cada 3 m^2 a 5 m^2, con lo que se obtiene un aumento de la densidad media del terreno muy apreciable.

Para que el terreno se licue con la vibración es preciso que su contenido en finos (limos más arcillas) sea prácticamente nulo. Con contenidos de finos casi nulos (inferiores al 5%) se consiguen densificaciones por la vibración de los equipos que se introducen en el terreno. Este tratamiento se denomina vibroflotación, ver Figura 3.6.

Figura 3.6 Proceso de Vibroflotación.

Fuente: Base de datos de RHG Ingeniería.

Para terrenos con un contenido en finos (entre el 5% y el 20%), la acción del vibrador produce una densificación en la proximidad del punto de actuación. La retirada del vibrador deja un hueco que se rellena con un material granular de aportación. Este procedimiento mixto de vibración con la inclusión de un material granular se denomina vibrosustitución.

Dado que en el proceso de dragado se retirarán las arcillas, podemos considerar que las arenas utilizadas para el relleno están limpias, esto es, que tienen menos del 5% de finos.

El proceso de ejecución de una vibroflotación en la zona de rellenos es el siguiente:

a. Preparación del terreno, de forma que se facilite la evacuación de las aguas y los movimientos de la maquinaria.

b. Replanteo. Se instalarán bases de replanteo que permitan restituir los puntos en caso necesario.

c. Acopio, cuando esté prevista la aportación de material granular.

d. Realización de la vibroflotación con la siguiente secuencia:

1. Introducir el vibrador por acción de su propio peso, de vibración y de la inyección de aire o agua a presión por su extremo inferior.

2. Cuando se alcanza la profundidad requerida, se suspende la inyección de agua o aire y se continúa la vibración provocando una consolidación del terreno próximo. En terrenos con contenidos de finos superiores al 5% se producen unas oquedades que se rellenan con la aportación de material granular.

3. Cuando vibrando en un punto se consigue la consolidación deseada se eleva el vibrador en torno a 50 cm y se repite la operación de vibrado.

Es importante comentar que en obras marítimas es adecuada la vibroflotación por vía húmeda por tres razones:

- Se dispone de agua sin costo.
- El nivel freático suele estar alto.
- La evacuación de las aguas no presenta problemas.

3.1.4 Cortes en Roca Submarina (en su caso).

Dadas las condiciones de la Laguna de Cuyutlán y con base en los estudios básicos realizados existe la posibilidad que existan zonas de afloramientos de roca, la cual ha sido clasificada como granito intemperizado, por tal motivo, en caso de que se llegará a presentar esta situación, se ha planteado el siguiente procedimiento a seguir.

La ejecución de trabajos de dragado en materiales rocosos representa uno de los escenarios más exigentes dentro de la ingeniería portuaria y marítima. Cuando el material a remover corresponde a roca clasificada como granito, el grado de complejidad aumenta significativamente debido a su elevada resistencia mecánica, baja deformabilidad y, en muchos casos, limitada presencia de discontinuidades que faciliten su fragmentación natural.

Es posible extraer roca sin explosivos, pero la viabilidad real depende de que la roca esté meteorizada, fracturada o de resistencia media; pero normalmente baja mucho el rendimiento y sube mucho el costo frente a otras opciones. PIANC[2] subraya que la selección del método de dragado en roca depende de una buena investigación geotécnica y de cómo interactúan las propiedades de la roca con el proceso de excavación.

En el presente apartado se desarrolla, desde un enfoque técnico y constructivo, la metodología más adecuada para la extracción de roca en ambiente marino sin el uso de explosivos. Este tipo de restricción es cada vez más común en proyectos ubicados en zonas ambientalmente sensibles, en proximidad a infraestructura existente o en áreas donde las vibraciones y ondas de choque no son aceptables.

3.1.4.1 Consideraciones geotécnicas.

La selección del método de dragado en roca depende de manera directa de las características del macizo rocoso. En este sentido, la clasificación del material debe ser interpretado con cautela, ya que el comportamiento real puede variar significativamente dependiendo de factores como el grado de meteorización, la presencia de discontinuidades, la orientación de diaclasas y la resistencia a compresión simple.

En formaciones altamente fracturadas o parcialmente alteradas, la roca puede presentar un comportamiento favorable a la excavación mecánica, permitiendo su fragmentación mediante herramientas de corte o desgarre. Por el contrario, en condiciones de roca sana, masiva y con bajo grado de fracturamiento, la resistencia del material puede dificultar considerablemente su remoción, reduciendo los rendimientos y aumentando el desgaste de los equipos.

En términos operativos, la excavabilidad del material está controlada por parámetros como la resistencia a compresión simple, el grado de fracturamiento, la orientación de discontinuidades y la abrasividad. Estos factores condicionan directamente la selección del equipo, el tipo de herramientas de corte y los rendimientos esperados. En roca altamente fracturada, es posible que la excavación mecánica se realice con relativa eficiencia, mientras que en roca masiva será necesario incorporar etapas previas de aflojamiento o corte.

Por lo anterior, resulta indispensable contar con una campaña geotécnica específica para dragado, que incluya ensayes de resistencia, evaluación del RQD, caracterización de discontinuidades y análisis de abrasividad, con el fin de ajustar la selección del equipo y estimar con mayor precisión los rendimientos esperados.

[2] PIANC (Asociación Mundial de Infraestructuras de Transporte Acuático) es una organización internacional técnica y sin fines de lucro, fundada en 1885. Proporciona asesoramiento experto y guías técnicas para el diseño, construcción, mantenimiento y operación sostenible de puertos, marinas y vías navegables (interiores y marítimas)

3.1.4.2 Equipos principales y su funcionamiento

La extracción de roca sin el uso de explosivos se basa en la aplicación de esfuerzos mecánicos concentrados capaces de superar la resistencia del material. Estos esfuerzos pueden manifestarse como corte, trituración, impacto o desgarre, dependiendo del equipo utilizado.

En ambiente marino, estos procesos deben ejecutarse mediante equipos montados sobre pontonas o embarcaciones especializadas, lo que introduce condicionantes adicionales relacionadas con estabilidad, precisión de posicionamiento y control del proceso bajo el agua.

La estrategia general consiste en transformar el macizo rocoso en fragmentos manejables mediante un proceso de aflojamiento o fragmentación inicial, seguido de su excavación, carga y transporte.

Uno de los equipos más utilizados para este tipo de trabajos es la retroexcavadora montada sobre pontona, conocida como backhoe dredger, ver Figura 3.7. Este sistema consiste en una excavadora hidráulica de gran capacidad instalada sobre una estructura flotante estabilizada mediante pilotes o spuds. La máquina opera mediante el uso de una pluma, brazo y cuchara especialmente reforzada para trabajar en roca.

Figura 3.7 Backhoe Dredger.

Fuente: https://www.iadc-dredging.com, 2026

El proceso de excavación con este equipo implica la penetración de la cuchara en el material mediante la aplicación de fuerza hidráulica, seguida del desprendimiento del material y

su elevación hacia la superficie. Posteriormente, la roca es descargada en embarcaciones auxiliares denominadas chalanes, que se encargan de su transporte hacia el sitio de disposición final.

La principal ventaja de este sistema radica en su precisión, ya que permite trabajar con alto control sobre la geometría del fondo y los taludes. Sin embargo, cuando la roca es demasiado resistente, la cuchara por sí sola no es suficiente para lograr una excavación eficiente, lo que hace necesario el uso de equipos complementarios.

En este contexto, los cortadores de tambor, o drum cutters, representan una solución eficaz para el aflojamiento de roca, ver Figura 3.8. Estos dispositivos consisten en cilindros rotatorios equipados con picos de corte que giran a alta velocidad, triturando la roca mediante un proceso continuo de desgaste. El drum cutter puede instalarse en el brazo de una excavadora, permitiendo trabajar de manera localizada y controlada.

Figura 3.8 Cortador de Tambor (Drum Cutters).

Fuente: https://www.epiroc.com, 2026

El uso de este equipo es particularmente ventajoso en entornos donde no se permiten vibraciones, ya que el proceso de corte es progresivo y no genera impactos bruscos. Además, permite perfilar superficies con gran precisión, lo que resulta útil en etapas finales del dragado.

Otra alternativa relevante es la draga de cortador-succión, que combina la fragmentación del material con su transporte hidráulico. Este equipo cuenta con una cabeza de corte rotatoria ubicada en el extremo de un brazo, la cual desintegra la roca mientras una bomba succiona la mezcla de agua y material fragmentado, enviándola a través de tuberías hacia el sitio de descarga.

La eficiencia de este sistema depende de la capacidad de la cabeza de corte para fragmentar el material en tamaños lo suficientemente pequeños para ser transportados hidráulicamente. En roca muy dura, este proceso puede volverse limitado, requiriendo cabezas de corte especializadas y altos niveles de potencia.

En condiciones donde la roca presenta un grado significativo de fracturamiento, puede emplearse un ripper mecánico, que es un implemento diseñado para desgarrar el material aprovechando sus discontinuidades naturales. Este equipo funciona mediante la aplicación de fuerzas de tracción concentradas, separando bloques de roca a lo largo de planos de debilidad.

Figura 3.9 Cortador de Draga.

Fuente: Base de datos de RHG Ingeniería.

Finalmente, para trabajos de precisión o en zonas críticas, pueden utilizarse sistemas de corte especializados como el hilo diamantado o los splitters hidráulicos. El hilo diamantado consiste en un cable recubierto con segmentos abrasivos que corta la roca mediante un movimiento continuo, mientras que los splitters hidráulicos generan presión interna en perforaciones previamente realizadas, provocando la fractura controlada del material. Estos métodos son altamente precisos y no generan vibraciones, aunque su baja productividad los limita a aplicaciones específicas.

3.1.4.3 Procedimiento constructivo.

El proceso de extracción de roca sin explosivos debe iniciar con una etapa de caracterización geotécnica detallada, que permita definir las propiedades del material y

seleccionar el equipo adecuado. Esta etapa incluye la realización de sondeos, ensayes de laboratorio y análisis estructural del macizo rocoso.

Posteriormente, se recomienda ejecutar un tramo de prueba en campo, con el objetivo de validar los rendimientos de los equipos y ajustar la estrategia constructiva. Esta fase es fundamental para reducir incertidumbre y optimizar la planificación del proyecto.

Una vez definida la metodología, se procede al aflojamiento de la roca mediante el uso de drum cutter, ripper u otro equipo de corte, dependiendo de las condiciones del material. Este proceso tiene como objetivo reducir la resistencia del macizo y generar fragmentos manejables.

A continuación, la roca aflojada es excavada mediante la retroexcavadora, cargada en chalanes y transportada fuera del área de dragado. Durante esta etapa, es fundamental mantener un control preciso de las cotas de excavación, utilizando sistemas de posicionamiento y monitoreo en tiempo real.

Finalmente, se realiza el perfilado del fondo, eliminando irregularidades y asegurando el cumplimiento de las especificaciones de diseño. En esta fase pueden utilizarse equipos de corte de alta precisión para ajustar detalles y remover puntos duros residuales.

3.1.4.4 Consideraciones operativas y ambientales

La adopción de metodologías mecánicas sin uso de explosivos presenta ventajas significativas desde el punto de vista ambiental, particularmente en entornos marinos sensibles como la Laguna de Cuyutlán.

La operación de equipos de dragado en roca requiere una planificación cuidadosa, considerando factores como la estabilidad de la pontona, las condiciones de oleaje, la logística de transporte y la disponibilidad de mantenimiento.

Desde el punto de vista ambiental, la eliminación del uso de explosivos representa una ventaja significativa, ya que evita la generación de ondas de choque que pueden afectar a la fauna marina. Asimismo, permite un mayor control sobre la dispersión de sedimentos y reduce la turbidez del agua.

3.1.4.1 Comentarios finales.

La extracción de roca tipo granito en ambiente marino sin el uso de explosivos es técnicamente viable mediante la aplicación de métodos mecánicos basados en corte, trituración y excavación controlada. La combinación de equipos como retroexcavadoras sobre pontona, cortadores de tambor y dragas de cortador-succión permite adaptar la metodología a las condiciones específicas del material y del sitio.

El éxito del proceso depende en gran medida de una adecuada caracterización geotécnica, de la selección correcta del equipo y de la ejecución de pruebas piloto que permitan validar los rendimientos. Bajo estas condiciones, es posible llevar a cabo el dragado de manera eficiente, segura y compatible con las restricciones ambientales del proyecto.

A pesar de su viabilidad, los métodos mecánicos presentan ciertas limitaciones, especialmente en presencia de roca masiva de alta resistencia. En estos casos, los rendimientos pueden disminuir considerablemente, incrementando los tiempos de ejecución y los costos operativos. Adicionalmente, el desgaste de herramientas y la necesidad de mantenimiento continuo deben ser considerados en la planeación del proyecto.

Por lo tanto, la selección definitiva del método deberá sustentarse en la caracterización geotécnica del material y en la validación de rendimientos mediante pruebas de campo, garantizando así la eficiencia y viabilidad del proyecto en el contexto específico de la Laguna de Cuyutlán.

3.2 Procedimiento Constructivo de la Estructura de Contención de Rellenos (Tablestaca).

Con base a la información generada por los documentos que conforman el proyecto ejecutivo para la construcción del muro de tablestacado se conforman las plantillas técnicas que serán responsables de llevar a cabo los trabajos de construcción y controles, así como seleccionar la maquinaria adecuada y con capacidad suficiente para la construcción de los muros de tablestacado metálico.

Es importante considerar que el proyecto contempla procesos y etapas independientes en su ejecución pero que tienen una continuidad al termino de cada proceso. De aquí surge la importancia de contar con una plantilla técnica con experiencia y conocimiento en la construcción de este tipo de proyectos.

3.2.1 Instalaciones Provisionales de Obra

Parte del procedimiento constructivo es la planeación y programación de los trabajos, así como la cuantificación de los volúmenes de obra, y para poder realizar todas estas actividades, es necesario contar con instalaciones provisionales de campo donde se realicen los trabajos de gabinete.

Las Instalaciones provisionales de campo, como oficinas, almacenes, talleres de mantenimiento, talleres de construcción, caminos de acceso, oficinas en los frentes de trabajo, se realiza un planteamiento para su mejor ubicación y funcionalidad, disponiendo terreno que previamente fue autorizado por la Residencia de ASIPONA Manzanillo y la Supervisión de la Obra.

Formando parte de las Instalaciones Provisionales de Obra, la construcción de plataformas para almacenamiento y estiba de los perfiles de acero (viguetas), tablestacas y tensores de acero, así como los talleres para limpieza mecánica (sand blasteo), y talleres para la aplicación de las protecciones mecánicas (protección anticorrosiva) y al sistema de tensores, con caminos y plataformas adecuados para las grúas y plataformas de transportación.

Estará incluido dentro de las instalaciones provisionales de obra la construcción de un muelle en un sitio autorizado por la ASIPONA Manzanillo para operar durante el proceso de la obra, como punto de atraque, carga y embarque de materiales (perfiles de acero y tablestaca) que forman parte del muro combinado de tablestaca.

Todas estas instalaciones quedarán registradas previamente antes del inicio de la obra, en un plano y estarán sujetas a la autorización de la residencia de ASIPONA Manzanillo y de la supervisión de la obra.

3.2.2 Levantamiento Topográfico y Batimétrico

Durante el periodo que se llevan a cabo la construcción de las instalaciones provisionales de la obra y construcción de los caminos de acceso, se realizan los levantamientos topográficos y batimétricos de las áreas que corresponden al proyecto y se colocan las referencias necesarias que serán ocupadas durante el proceso de construcción. Se cuantifican los volúmenes de obra, y se concilian con la supervisión de la obra y se informa a la residencia de ASIPONA Manzanillo, sobre la existencia de diferencias de volúmenes con respecto a los volúmenes de presupuesto contractual en caso de que existan en mayor o menor diferencia.

3.2.3 Planeación y Programación de Obra.

Forma parte de una de las responsabilidades del representante técnico de la empresa contratista, revisar el programa de obra contractual y con la cuantificación en obra de los volúmenes apoyado por los levantamientos topográficos y batimétricos y los planos del proyecto ejecutivo recibidos para construcción realizar los ajustes de cantidades que correspondan, conciliarlos con la supervisión de la obra e informar a la residencia de ASIPONA Manzanillo si existen diferencias.

La cuantificación de los volúmenes de obra que se realiza durante el proceso de construcción de las instalaciones provisionales en obra servirá para revisar los volúmenes de materiales por adquirir. Por las características, especificaciones y cantidades de los perfiles metálicos por instalar, es recomendable hacer el requerimiento lo más inmediato posible, es decir, adelantándose al proceso de construcción de las instalaciones de obra, y debido a que los materiales son productos de importación y requieren tiempos considerables para su fabricación y transportación marítima dependiendo de la capacidad de fabricación del proveedor y la solvencia económica de la empresa Contratista.

Se realiza el requerimiento de la maquinaria más apropiada y con la capacidad necesaria para ejecutar las actividades de obra, con base al proceso constructivo, siendo de vital importancia y de acuerdo con las características de los trabajos por realizar, la construcción de un muelle que sirva para atracar y cargar todos los perfiles metálicos que serán instalados en las Terminales No. 1 y No. 2 como elementos de contención de rellenos. El planteamiento y la construcción del muelle, así como la ubicación de este dentro de la zona portuaria de Cuyutlán[3].

Dentro de los objetivos de revisar la planeación y programación de la obra, se encuentra la ratificación de la fecha de ingreso de los equipos para construcción, con base a la planeación, así como la tramitación de permisos para ingreso de los equipos marinos como chalanes, remolcadores, lanchas y operadores ante las autoridades del puerto. Y un punto importante confirmar la vigencia del permiso de vertimiento del proyecto, con la finalidad de que los trabajos cuenten con la continuidad necesaria desde el inicio hasta la conclusión de las actividades.

Todos los insumos que intervienen y se requieren para llevar a cabo la construcción de la obra, se encuentran dentro de las cuantificaciones de los conceptos de proyecto y se planea su adquisición, suministro e ingreso para que el programa de obra se cumpla, a su vez este proceso sirve para confirmar y corregir cualquier deficiencia que se haya tenido durante el proceso de licitación.

Durante el proceso de planeación y programación de obra, se realiza la selección y el ingreso del Personal Técnico adecuado y con experiencia en este tipo de proyectos, incluyendo el personal administrativo, mecánico, operadores y obrero necesario para dar cumplimiento al programa de obra.

3.2.4 Construcción de Instalaciones Provisionales de Obra.

Las oficinas de campo, talleres de mantenimiento y de construcción, almacenes de materiales, comedor y caminos de acceso para ingreso al muelle de carga y caminos de acceso para ingreso a la obra deberán contar con el permiso y autorización por parte de la residencia de ASIPONA Manzanillo, con base al planteamiento y necesidades de espacio planteado por la empresa contratista, donde las áreas necesarias para construir las instalaciones provisionales se encuentren libres de impedimentos y permisos.

Por las características propias de proyecto y por el tiempo de ejecución de las obras, las oficinas de campo se deberán instalar en el lugar más cercano a la obra, contando con el suministro de energía eléctrica (plantas portátiles de energía eléctrica), agua potable (tanques de almacenamiento), servicios sanitarios portátiles suficientes.

[3] Como parte de los trabajos de construcción, el muelle deberá estar considerado dentro del presupuesto de obra, incluyendo la ingeniería y los estudios necesarios para su construcción.

En el caso del almacén de materiales deberá contar con un espacio techado y con estantes para materiales menores y unas 36 plataformas para almacenar los perfiles de acero (viguetas) 2,650 piezas de 15.00 y 2,650 piezas de 31.50 m de longitud, tablestacas 2,650 piezas de 25.00 m y 2,650 piezas 15.00 m con todos sus diferentes tipos de conectores, tensores y herrajes metálicos, considerando que las estibas no deben ser altas, y espacios suficientes para maniobras de carga y estiba con grúas y plataformas con dolly para su traslado.

El taller de mantenimiento para maquinaria deberá contar con un cobertizo amplio y una fosa para mantenimiento y reparación de equipo mayor como grúas, tractocamiones, remolcadores y lanchas y un tanque para almacenamiento de combustible (diésel) con capacidad suficiente para el suministro del equipo en tierra y el marítimo.

En el caso de talleres de construcción se deberán construir cuatro talleres a cubierto con suficiente altura para el área de limpieza mecánica (sand blast), dos para perfiles de acero viguetas 31.50 m y de 15.00 m y dos más para tablestacas de 25.00 m y de 15.00 m, así como sus áreas para estiba, almacenaje, para maniobras de descarga y carga con Grúas y plataformas con Dolly para su transporte.

Y por lo que corresponde al proceso de protección anticorrosiva que deberán llevar las tablestacas, viguetas, tensores y herrajes de conexión se deberán construir otros cuatro talleres a cubierto con altura suficiente para la aplicación de las protecciones dos para viguetas de 31.50 m y 15.00 m y dos para 25.00 m y 15.00 m. así como los espacios necesarios para estiba, almacenaje, maniobras de descarga y carga con grúas y plataformas con dolly para su transporte.

En estos espacios de talleres deberán estar considerados los depósitos a tanques para residuos sólidos y líquidos, incluyendo su manejo y disposición final, que el personal de impacto ambiental de la empresa contratista debe controlar, así como las medidas de mitigación que sean necesarias implementar para no incurrir en faltas con lo indicado en el resolutivo de impacto ambiental.

En lo que corresponde a la construcción de los caminos de acceso, estos deberán realizarse con entendido de que serán utilizados durante los tiempos de lluvias y que deben ser lo suficientemente amplios considerando un sentido de ida y otro de regreso con plataformas cargadas con materiales y el paso para tránsito pesado y de maquinaria, estos caminos estarán contemplados en el interior para interconexión entre el almacén y los talleres, así como el de acceso a las instalaciones provisionales de obra y los que van al muelle de carga. La construcción de estos caminos contara con una estructura de terracerías apropiada, como la instalación de una subrasante, subbase y base, con bombeo y las pendientes que la topografía propia del lugar obligue a su construcción.

Es importante también contemplar dentro de los caminos de acceso a la obra el que se pueda ingresar a la zona de construcción en forma directa, es decir considerar que la construcción de los muros de tablestaca y perfiles de la pantalla principal y secundaria se encuentran en el extremo opuesto al de las Instalaciones provisionales de obra, y que por necesidad es necesario construir caminos de acceso con estructura de terracerías de las mismas características que los anteriores caminos de acceso con un embarcadero provisional para lanchas que trasladen al personal de construcción.

Debido a la ubicación del proyecto es necesario construir un comedor con todos los servicios que esto requiera, como suministro de agua potable, energía eléctrica, gas, servicios sanitarios, y aire acondicionado para el personal, técnico, administrativo, mecánico, operadores y obrero, con capacidad para 150 personas.

3.2.5 Construcción del Muelle para Carga de Tablestaca y Perfiles de Acero.

Con base a las necesidades del proyecto la empresa contratista construirá dentro de la Laguna de Cuyutlán un muelle provisional para atraque y carga de los perfiles de acero y tablestaca para el muro principal y el muro secundario, cuya ingeniería, proyecto ejecutivo y costo de construcción están incluidos dentro del presupuesto de tablestacado de las terminales No. 1 y No. 2.

En la elaboración del proyecto ejecutivo del muelle se contemplaron los costos del estudio de mecánica de suelos, levantamiento topográfico y batimétrico, diseño del muelle (análisis estructural y sísmico). Se considera un primer planteamiento para fines de construcción de muelle, una cimentación a base de pilas de concreto de 1.20 m de diámetro coladas en sitio de 21.50 m de longitud, una superestructura con una losa de concreto armado de 1.00 m de espesor, de 52.50 m de longitud por 25.00 m de ancho, con su pantalla de atraque y trasera, con relleno en parte anterior del muelle, con un enrocamiento formando un talud 1:1 y un relleno con material calidad subrasante, subbase y base para formar el acceso al muelle que va a ser utilizado para carga de perfiles metálicos y tablestaca para su transportación marina hasta el sitio de construcción de los muros indicados en el proyecto ejecutivo.

De acuerdo con el programa de obra se solicitaron y adquirieron los materiales para construcción de las pilas, como es el acero de refuerzo, las placas de acero para la fabricación de los ademes, las secciones de cimbras perdidas y recuperables, la fabricación del escantillón para construcción de las pilas y después para el hincado de tablestacas. Así como el ingreso del equipo solicitado, cortadoras de varilla y dobladoras de varilla eléctricas, para el taller de corte y habilitado de acero de refuerzo, soldadoras de combustión para ejecutar los empalmes soldables de los armados de las pilas en las varillas de 1” de diámetro en adelante que el proyecto indique. Conforme llega el equipo, también ingresa el personal obrero (cuadrillas de fierreros) y operadores para las grúas y para los tractocamiones que se encargaran de transportar los armados de las pilas al sitio de construcción del muelle.

Durante el proceso de corte, habilitado y armado del acero de refuerzo para las pilas del muelle, se realiza el levantamiento topográfico y batimétrico donde se ubicará el muelle y se complementa con el levantamiento batimétrico que anteriormente se realizó para la elaboración del proyecto de dragado. De igual forma se fabrican los ademes metálicos, las cimbras metálicas tanto las secciones no recuperables (perdidas), como las recuperables en el taller de soldadura. En el proceso de habilitado del acero de refuerzo de las pilas del muelle la cuadrilla de fierreros emplea las cortadoras y dobladoras eléctricas y continua con su proceso otra cuadrilla de fierreros que se encarga de armar el acero de refuerzo de acuerdo con los diámetros y secciones indicadas en los planos del proyecto, tomando en consideración que los empalmes de varillas cuyo diámetro es de 1” en adelante deben ser uniones soldables y que no debe haber más del 30% en una misma sección.

Conforme se van terminando los armados de las pilas, una cuadrilla de soldadores inicia con las uniones soldables, realizando los cortes biselados con los equipos de corte oxi-acetileno y ejecuta los empalmes empleando ángulos de acero de respaldo y en la unión soldable emplean electrodos E-7018 o lo que indique el proyecto con la utilización de las plantas de soldar. El ingeniero responsable de los trabajos del muelle informa y solicita a la supervisión de la obra la revisión y autorización de los armados de las pilas a los que se realizaron las uniones soldables, a los cuales ya les fueron realizadas las pruebas no destructivas y que el personal de laboratorio de radiografías contratado entrego los reportes donde corrobora que las uniones soldables cumplen con la calidad de los trabajos de soldadura.

Durante el periodo de fabricación de los ademes, las cimbras metálicas, escantillón y fabricación de armados de las pilas, se integra al proyecto el equipo para construcción de las pilas, personal obrero operadores para grúa, equipo de perforación, chalan o Flexi-Float, remolcador, lanchas con motor fuera de borda, plantas de soldar, compresor estacionario de 250 PCM, tubo Air-Lif y el tubo tremie. De acuerdo con las fechas indicadas en el programa de obra conciliado con la residencia de ASIPONA Manzanillo y la supervisión de la obra, se da inicio a los trabajos de construcción de la pilas, ordenándose a la cuadrilla de topografía realizar el trazo del primer eje de pilas, para que se proceda a mover el equipo de construcción de pilas, realizando las maniobras necesarias para subir la grúa al chalan en el sitio preparado con anticipación y con la grúa se ejecutan las maniobras para cargar al chalan el equipo de perforación, planta de soldar, compresor, tubo Air-Lif, tubo tremie, escantillón, perfiles de acero ligeros, el ademe, la cimbra metálica perdida, recuperable de las pilas y el armado de la pila. Los maniobristas y operadores avisaran que se encuentra todo lo necesario para que se le indique al operador del remolcador que traslade al chalan al sitio de construcción indicado por el personal de topografía.

El Ingeniero responsable de los trabajos de la empresa contratista, le informa a la supervisión de la obra sobre el inicio de los trabajos para que verifique y autorice, los trazos y niveles de la primer pila y se autorice la actividad de perforación, se posicione el chalan con los sancos y se instale el escantillón con la grúa y con base al trazo del proyecto se fija el ademe

metálico con perfiles metálicos en la parte superior del escantillón, y se monta a la grúa el equipo de perforación y de acuerdo al cheque topográfico de la supervisión de la obra, se autoriza el trabajo de perforación empleado la broca y bote adecuado con el tipo de material indicado en el estudio de mecánica de suelos en el interior del ademe, no sin antes verificar la verticalidad de la perforación y se de inicio a la perforación y extracción del material producto de la perforación, depositándolo lateralmente a un lado del escantillón. Conforme avanza la perforación al interior del ademe este va bajando, se continua la perforación hasta el nivel de desplante indicado en el proyecto, se inserta la cimbra perdida con la cimbra recuperable y se recupera el ademe metálico.

se realiza la colocación de las donas de concreto al armado de la pila para asegurar que el recubrimiento del acero de refuerzo indicado en los planos se cumpla, se realizan las maniobras de estrobado, izaje del armado de acero de refuerzo de la pila entre los maniobristas y el operador de la grúa, la cual coloca el armado en el interior de la cimbra metálica, respetando los niveles indicados en los planos. Se le informa a la supervisión de la obra de los trabajos ejecutados para que sean verificados y autorice el vaciado de concreto de la pila. La empresa contratista contrato con anticipación al inicio de los trabajos, el servicio de suministro de concreto, el equipo de bombeo y el laboratorio, el cual se programa durante la ejecución de los trabajos, para que cuando se autorice el vaciado de concreto, llegue el volumen de concreto necesario y el personal de laboratorio que verifica el tiempo de traslado, revenimientos y saca las muestras del concreto suministrado para llevar a cabo las pruebas de resistencia del concreto.

Para el vaciado de concreto se emplea una cubeta con compuerta manual que es llenada por la olla que transporto el concreto a la obra, la cubeta se iza con la grúa y se acopla al tubo tremió con estrobos, se abre la compuerta manual y se vacía el concreto de la cubeta al tubo tremie hasta llenar completamente la pila, durante el proceso de vaciado con el tubo tremie re realiza un chaqueteo con el apoyo de la grúa, con la finalidad de realizar un mejor acomodo del concreto en el interior de la cimbra hasta llegar al nivel tope de colado considerando para este tipo de trabajo dejar el nivel superior de concreto 1.00 m, arriba del nivel de proyecto, con la finalidad de que el concreto de la pila sea concreto sano y el metro de concreto arriba del nivel de proyecto sea demolido, considerando que pudiera estar contaminado. una vez que se terminó el vaciado de concreto se deja reposar el concreto para que termine de fraguar y adquiera su resistencia, los cual permitirá retirar la cimbra recuperable, dicha actividad debe realizarse con buzos equipados con su equipo de buceo y con apoyo de la grúa que se encuentra arriba del chalan. Toda la secuencia de trabajo descrita anteriormente para la construcción de las pilas se repite hasta el terminar de construir la última pila indicada en el proyecto.

Durante el proceso de construcción de las pilas, el personal del taller de soldadura habilita y forja las mordazas, perfiles de acero para la obra falsa y la cuadrilla de carpintería habilita la cimbra de contacto para la superestructura del muelle, para trabes, contratrabes, losa y muros pantalla y de igual forma la cuadrilla de fierreros corta y habilita el acero de refuerzo para la superestructura. Es importante considerar que conforme avanza el proceso de construcción de las pilas, también se realice el descabezado de pilas, con personal obrero, ocupando para la

demolición del concreto el compresor estacionario con pistolas neumáticas para la demolición del concreto contaminado que quedo arriba del nivel de proyecto, empleando balsas y andamios que son trasladados con el apoyo de lanchas con motor fuera de borda, teniendo la precaución de que el material producto de la demolición sea depositado en las balsas y sea retirado hasta el sitio autorizado por la SEMARNAT.

Continuando con el proceso de construcción del muelle y de acuerdo con el programa de obra el ingeniero responsable de los trabajos de la empresa contratista, le indica al personal de topografía, realizar la colocación de niveles y ejes en la pilas de concreto ya descabezadas, para iniciar con la colocación de las mordazas metálicas que fueron fabricadas en el taller de soldadura y que servirán de apoyo para instalar la obra falsa, formada por perfiles de acero y sobre estos se coloque la cimbra de contacto, como es el fondeo de la losa, trabes, contratrabes, muros pantalla.

Para la instalación y fijación de las mordazas se emplean balsas fabricadas con tambos vacíos de 200 l, polines y tablones de madera, a las que se les montan andamios para trabajar en altura y alcanzar el nivel donde se instalan las mordazas, las cuales son acarreadas y trasladadas en las balsas con el apoyo de lanchas con motor fuera de borda. Las mordazas se instalan y se fijan con tornillos de 1” de Ø X 4”, no sin antes realizar las perforaciones en la pila, con lo cual se sujeta y fija la mordaza en el nivel requerido, esta actividad es ejecutada por la cuadrilla de maniobristas y carpinteros de obra negra, que tienen experiencia en obras marítimas. Conforme avanza la colocación de mordazas otro grupo de trabajo traslada las viguetas de acero que forman la obra falsa y las acarrean en las balsas hasta donde fueron instaladas las mordazas, las suben y las sujetan a las mordazas formado cuadriculas con base a las áreas del proyecto. Es importante mencionar que la obra falsa que es formada por las viguetas de acero son secciones que fueron producto de un diseño y calculo derivado de una distribución de cargas para vigas simplemente apoyadas en sus extremos y de este cálculo se deriva la sección y peralte de la viga que se utiliza en la obra falsa para la Superestructura.

De acuerdo con el avance de colocación de obra falsa otro grupo de trabajo formado por cuadrillas de carpinteros de obra negra que habilito la cimbra de contacto para la superestructura, acarrean los fondos y costados de trabes, contratrabes, losa y muros pantalla, empleando balsas y las lanchas para su traslado hasta el sitio de su instalación, respetando los ejes y niveles que el personal de topografía referencio con anticipación, los fondos de la cimbra de contacto son fijados a la obra falsa ya colocada, y posteriormente los costado de trabes, contratrabes y muros pantalla, alineado los costados así como la colocación de sus troqueles para rigidizar los costados.

La cuadrilla de fierreros que termino de habilitar el acero de refuerzo durante el periodo de colocación de la obra falsa y fondeo de la superestructura inicia con el traslado del acero de refuerzo habilitado para la superestructura de acuerdo a los diámetros indicados en los planos del proyecto, e inicia con el armado de la superestructura de acuerdo con las secciones y diámetros indicados en los planos del proyecto, conforme va terminando, coloca las calzas de concreto en la parrilla inferior y en los costados para respetar el recubrimiento del acero de refuerzo durante el

proceso de vaciado de concreto. Durante el periodo de colocación del acero de refuerzo el personal de topografía ubico y trazo el sitio donde se deben de instalar y fijar las anclas para las bitas de amarre y las anclas para las defensas marinas.

Una vez que se terminan de colocar las anclas de las bitas y defensas, y se concluye la colocación de costados en las paredes de las pantallas de superestructura, se realiza el troquelamiento exterior de la cimbra, se alinea y nivelan los costados exteriores, y se le indica a la cuadrilla de topografía que verifique la cimbra y coloque las referencias para el vaciado de concreto. La cuadrilla de albañilería que será responsable del vaciado de concreto en la superestructura inicia con la actividad de limpieza, sopleteando toda el área de colado, el ingeniero responsable de los trabajos avisa a la supervisión de la obra, sobre el termino de los trabajos de la superestructura para que los verifique y autorice el vaciado de concreto, el cual se programó con anticipación para su suministro, incluyendo la bomba de concreto. Adicionalmente deberá considerarse que, para el proceso las condiciones ambientales sean las óptimas para evitar condiciones de lluvia o calor extremo que produzca efectos negativos al concreto. Una vez que se cuenta con la autorización de la supervisión de la obra para realizar el vaciado de concreto de la superestructura, se solicita el suministro de concreto, la bomba de concreto, el personal de laboratorio y se preparan los vibradores de concreto, plantas de alumbrado y el personal obrero necesario, se verifica la calidad del concreto conforme llega a la obra por el personal de laboratorio y se realiza el vaciado de concreto en forma ordenada, vibrando correctamente el concreto que está acomodándose y nivelándose con respecto a las referencias que dejo el personal de topografía, se le da el acabado indicado en los planos de proyecto y se aplica la membrana de curado a toda la superficie que ya cuenta con el acabado y el concreto tiene ya su fraguado inicial.

Después de haberse realizado el vaciado de concreto se dejará el tiempo necesario para que el concreto adquiera su fraguado y resistencia apropiada antes de realizar el retiro de la cimbra de contacto. Para el retiro de la obra falsa y mordazas metálicas, se deberá contar con la constancia del laboratorio, que el concreto cumplido con la resistencia de proyecto. De acuerdo con el programa de obra se realiza la instalación de la bitas y defensas que están indicadas en los planos del proyecto, para poder dejar listo el muelle para su operación, realizando la limpieza final.

Es importante considerar que después de construir el muelle se deberá colocar en la pantalla posterior, el relleno de roca que se indica en los planos, con grúa y almeja para tener un acomodo adecuado, formándose con el talud de roca un aproche que evite la fuga de material de relleno que se empleará para la construcción del acceso al muelle. Al término de la colocación de la roca, se inicia la colocación del material de subrasante, tendiéndolo en capas no mayores de 0.20 m, con equipo para formación de la estructura de terracerías, empleando una motoconformadora, un vibrocompactador de 10 ton con rodillo liso, un compactador neumático con tándem, una pipa de agua de 10 m3 de capacidad. Se suministrara el material de banco calidad subrasante con los camiones volteo formándose un camellón al cual se le incorpora

humedad con la pipa de agua y con la motoconformadora se realiza el mezclado del material homogenizando todo el material con el porcentaje de humedad adecuado que nos permita obtener la compactación de proyecto, se extiende el material de subrasante y se conforma una capa de 0.20 m, nivelada, se procede a realizar la compactación con el rodillo vibrocompactador y con el rodillo neumatico tipo tándem, al concluir la compactación de la capa se le informa al personal de laboratorio para que proceda a realizar las calas a la capa terminada y determine si cumplió con el grado de compactación del 90% indicado en el proyecto. este proceso de relleno del material de subrasante para el acceso al muelle se repite en las siguientes capas hasta llegar al nivel inferior de la capa de subbase.

En el caso de la capa de subbase y base el procedimiento constructivo es igual por ser espesores no mayores a 0.20 m, las actividades de trabajo son idénticas al de las capas inferiores de material tipo subrasante con la diferencia de la calidad de los materiales que es subbase y base, el grado de compactación para la subbase es del 95%, y para la base es del 100%, así como el contenido de humedad y en el caso de la superficie de acabado de la subbase y base se deben de respetar los niveles de proyecto, lo cual se logra después de conformar la capa y se compacta, se afina la superficie con la motoconformadora, apoyada por los niveles de referencia que instalo la cuadrilla de topografía. posteriormente se realizan las pruebas de compactación por el personal de laboratorio que de acuerdo con las calas realizadas determina si la capa cumplió con el grado de compactación especificado en el proyecto.

Con la conclusión de los trabajos de terracerías realizados para formar el acceso al muelle se puede disponer de la estructura de muelle para los fines de atraque y carga de los materiales que se emplearan para la construcción de los muros de tablestacado, y que es prioritario para poder realizar los trabajos una vez que se haya recibido los materiales en el almacén y se les aplique los procedimientos de limpieza mecánica y protección anticorrosiva.

3.2.6 Limpieza mecánica (Sand Blast) de los Perfiles Metálicos.

Conforme al programa de obra después de haberse adquirido y cumplido el periodo de fabricación, transporte marítimo, e ingresado de los materiales al almacén de la obra, así como haberse construido los talleres, patios de maniobras, plataformas para almacenaje y estiba se inicia con los trabajos de limpieza mecánica, avisando al personal de supervisión de la obra sobre estas actividades y con el ingeniero responsable por parte de la empresa contratista se realicen los controles adecuados para cada proceso.

El sobrestante encargado del taller de limpieza mecánica le indica a los operadores de la grúa sobre neumáticos con pluma telescópica inicie la carga a una plataforma con dolly del patio del almacén de vigas y tablestacas que van en los muros y las traslade al taller de sand blasteo para que se realice la limpieza con chorro de arena en todo el perímetro de cada perfil en una longitud de 5.50 m que corresponde del nivel -2.00 al nivel +3.50 que es la parte superior de las vigas y tablestacas así como de los tensores y perfiles que son empleados para la sujeción y

fijación del sistema de tensado indicado en los planos del proyecto. Antes de iniciar las actividades de limpieza mecánica, cada vigueta y tablestaca es revisada por el personal del taller que los conectores se encuentren sin defectos que impidan la correcta unión entre viguetas y tablestacas, un grupo de soldadores del taller se encargan de corregir los conectores que durante el traslado a la obra sufrieron algún desperfecto.

Para realizar las actividades de limpieza mecánica, se emplean compresores estacionarios de 350 PCM, ollas para sand blast, mangueras de alta presión y pistolas de aire que ejecutan el lanzado de la arena silica a las paredes metálicas y son operadas por los oficiales de sand blast y sus ayudantes, los cuales se apoyan con una grúa sobre neumáticos con pluma telescópica con capacidad suficiente para realizar las maniobras de carga y acomodo de los perfiles metálicos en los bancos de trabajo, la limpieza consiste en aplicar el chorro de arena con alta presión para que se eliminen las grasas, óxidos o escorias que pudieran tener los perfiles hasta dejar la superficie limpia a metal blanco en la longitud de 5.50 m en lo que va hacer la cabeza de cada pieza durante el proceso de hincado de cada perfil.

Figura 3.10 Proceso de Sand Blast.

Nota: Imagen ilustrativo
Fuente: https://eltamaprimaindo.com/, 2026

Debido a la magnitud del proyecto y la gran cantidad de perfiles (viguetas) y tablestacas, cada uno de los cuatro talleres que se construyeron cuenta con su equipos y personal obrero el

cual de acuerdo al programa de obra, tiene establecida la producción diaria tanto para el muro de la pantalla principal como el de la pantalla secundaria, así como los equipos para carga y transporte del almacén de materiales al taller de limpieza mecánica y los que después de terminarse la limpieza mecánica deberán trasladar los materiales al taller de aplicación anticorrosiva.

El mismo proceso que se utiliza para las vigas y tablestacas es aplicado a los tensores y los perfiles metálicos del sistema de tensado, pero después de haber concluido las viguetas y tablestacas ya que de acuerdo con el programa de obra estos se instalaran una vez que en el frente de trabajo se tenga el espacio para poder iniciar su montaje e instalación.

3.2.7 Aplicación de Protección Anticorrosiva a los Perfiles Metílicos.

Una vez que cada perfil de acero (vigueta) o tablestaca se encuentra limpia, la grúa con pluma telescópica carga al tractocamión con plataforma y dolly los perfiles de acero y se trasladan a uno de los dos talleres de protección anticorrosiva, donde otra grúa con pluma telescópica descarga los perfiles metálicos (viguetas o tablestacas) y los coloca en los bancos del taller donde se realizara la aplicación de primarios anticorrosivo ES-300, para lo cual los oficiales pintores y sus ayudantes emplean un compresor eléctrico de aire para pintar, una cubeta de 20 l., presurizada con manguera y pistola, con los cuales se cubre el perímetro de cada perfil, apoyados por una grúa con pluma telescópica al terminar de cubrir la superficie lo acomoda en otro banco de trabajo donde se espera a su secado antes de que sea cargado para continuar con su proceso de protección. La grúa con pluma telescópica continua con su trabajo descargando los perfiles que provienen del taller de limpieza mecánica en los bancos que están disponibles para su protección con ES-300.

Con respecto a los tensores y perfiles de acero del sistema de tensado, se les realiza la misma aplicación de protección anticorrosiva de ES-300, después de concluir con las viguetas y tablestacas.

Una vez que se terminó el tiempo de secado de cada perfil (vigueta o tablestaca) una grúa con pluma telescópica carga los perfiles a otro tractocamión con plataforma y dolly, para que sean trasladados al otro taller de protección anticorrosiva que es el de RE-36.

Los perfiles de acero y viguetas o tablestacas que concluyo su proceso de secado y fueron cargados y trasladados a uno de los dos talleres para su protección anticorrosiva con RE-36, son descargados por una grúa con pluma telescópica en los bancos del taller, para que los oficiales pintores realicen la aplicación con el anticorrosivo RE-36, utilizando equipos similares para su ejecución como son un compresor eléctrico de aire para pintar, una cubeta de 20 l, presurizada con manguera y pistola, con los cuales se cubre el perímetro de cada perfil, apoyados por una grúa con pluma telescópica al terminar de cubrir la superficie lo acomoda en otro banco de trabajo donde se espera a su secado antes de que sea cargado para que sea enviado para su hincado. La

grúa con pluma telescópica continua con su trabajo descargando los perfiles que provienen del taller de protección anticorrosiva de ES-300 y los coloca en los bancos que están disponibles para su protección con RE-36.

Todos los perfiles de acero viguetas, tablestacas, tensores y perfiles del sistema de tensado que les fue aplicado la limpieza mecánica, protección anticorrosiva con ES-300 y RE-36, son cargados y trasladados a los sitios de hincado o en su defecto a una plataforma para su estiba y conforme se tenga el sitio para su hincado o montaje serán trasladados al muelle construido para la carga de al chalan y para su hincado.

3.2.8 Hincado de Perfiles Metílicos HZ y AZ.

El proyecto de tablestacado contempla el suministro e hinca de diversas secciones de perfiles HZ y tablestacas tipo AZ, en el proceso de hinca los trabajos se desarrollarán en agua.

Si bien, las tablestacas son adecuados en terrenos granulares y que presenten facilidad para su instalación mediante hinca. La hinca de tablestacas no es viable, o presenta grandes dificultades, cuando hay que atravesar terrenos muy consolidados como es nuestro caso.

Sin embargo, en este caso se recomienda la hinca de perfiles con una inercia adecuada a la operación a realizar, y en todo caso, con un reforzamiento en la punta, asimismo, se puede usar durante la hinca el chiflón de agua.

La hinca de elementos en suelos granulares compactos como las arenas, especialmente en terrenos secos, presentan serias dificultades que pueden resolverse mediante la inyección de agua a presión en la punta del pilote o la tablestaca o en alojamientos previamente preparados en sus caras. La presión del agua, de entre 0.4 y 4 MPa, debe ser apropiada al tipo de terreno y al elemento que se va a hincar, con un caudal de alimentación permanente de entre 72 y 900 m^3/h.

Este procedimiento puede ser suficiente para la hinca, pero lo usual es combinarlo con otros sistemas de tipo dinámico, especialmente la vibración. La hinca con chorro de agua es muy recomendable en zonas donde el rechazo se presente al 100 %, como en los terrenos arenosos. Sin embargo, en suelos arcillosos, la eficacia de la inyección de agua es prácticamente nula. En terrenos granulares con gravas gruesas y bolos, la inyección de agua puede no movilizarlas, por lo que el efecto también es bajo. En cualquier caso, hay que prever las consecuencias que puede tener en el entorno de la hinca por la pérdida de cohesión que sufrirá el terreno.

Las normas obligan a que el chiflón de agua se detenga entre 2 a 4 m por encima de la profundidad de desplante prevista en proyecto, puesto que el suelo se afloja. Por tanto, la hinca se terminará mediante un procedimiento ordinario con un martillo hidráulico. También se suspenderán los trabajos si la tablestaca empieza a torcerse debido a una perturbación excesiva del terreno.

En caso de que el chiflón de agua resulte infructuoso, en el último de los casos se deberá realizar perforación previa hasta 3 m antes de la profundidad de desplante indicada en el proyecto y a partir de este punto, se realizará la hinca mediante martillo.

3.2.9 Suministro, Manejo y Almacenamiento

Se deberá suministrar los elementos con las dimensiones y las características físicas señaladas en los planos y demás documentos del proyecto.

El manejo y el almacenaje de las tablestacas se realizarán de manera de garantizar la mayor seguridad de las personas e instalaciones circundantes a la obra, atendiendo la normatividad al respecto. Asimismo, el transporte y manejo del tablestacado deberán efectuarse con el mayor cuidado, para evitar cualquier deformación, ranuras, quebraduras y astilladuras.

Las piezas deberán ser almacenadas en sitios limpios en todo momento, bien drenados y protegidos de los efectos del agua. las piezas deberán ser separadas mediante trozos de madera durante el almacenamiento, para evitar deterioros que se puedan presentar por el contacto directo entre ellas o por cualquier otro agente, tales como el cambio de geometría, daños en los elementos de unión y posibles revestimientos que se presenten.

Se pondrá especial cuidado en la forma de almacenamiento y la cantidad por apilamiento, para evitar daños por solicitaciones estructurales no consideradas en el diseño de los elementos.

3.2.10 Equipo.

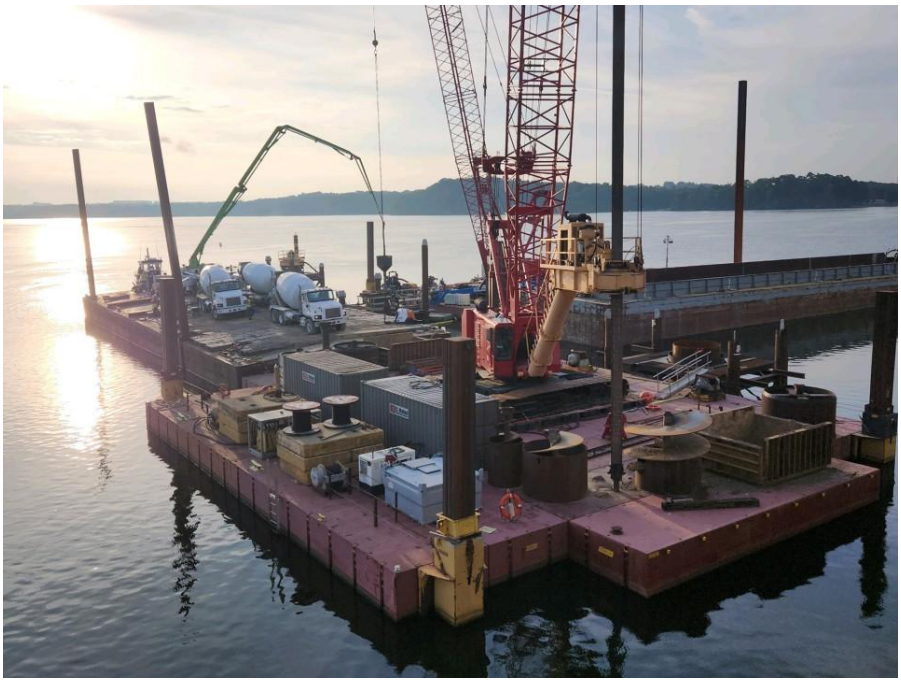
El equipo que se utilice para el traslado, izaje e hincado de la tablestaca, será el adecuado para obtener la calidad especificada en el proyecto, en cantidad suficiente para producir el volumen establecido en el programa de ejecución.

Dicho equipo será mantenido en óptimas condiciones de operación durante el tiempo que dure la obra y será operado por personal capacitado. Si en la ejecución del trabajo y a juicio del Contratista, el equipo presenta deficiencias o no produce los resultados esperados, se suspenderá inmediatamente el trabajo en tanto que la Contratista corrija las deficiencias, lo reemplace o sustituya al operador.

3.2.11 Hinca

Se deberá disponer de guías para las tablestacas, las cuales pueden consistir en una doble fila de tablones de mayor sección, colocados a poca altura del suelo, de forma que el eje del hueco intermedio coincida con el de la pantalla de tablestacas a construir.

Figura 3.11 Equipo Marino para Instalación de Tablestaca.



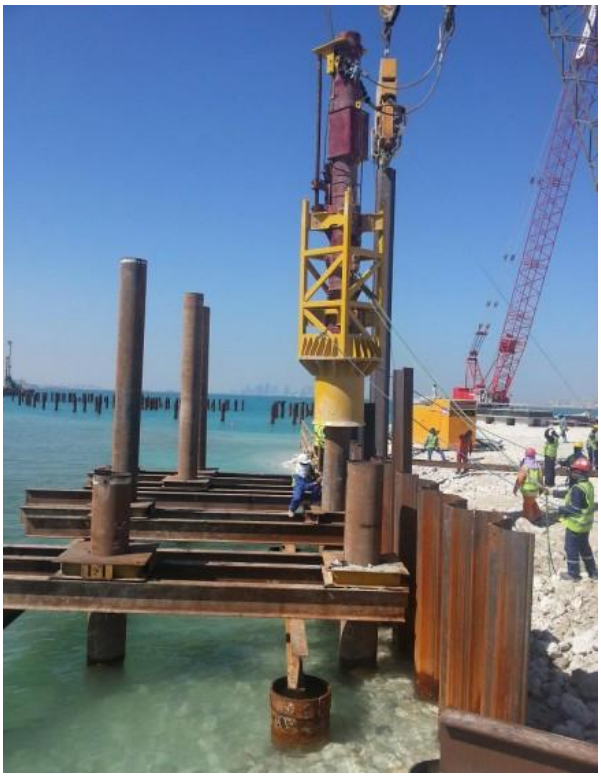
Nota: Imagen ilustrativo

El tablestacado se hincará mediante martillo, ver Figura 312, en este caso, el martinete puede ser de gravedad o de cualquier tipo de acción que se use normalmente en la hinca de pilotes. Si se hinca con martinete, las cabezas de las tablestacas se deberán proteger por medio de accesorios adecuados, para evitar deformaciones o deterioro por los golpes. Estos trabajos se complementarán con sistemas de inyección de agua a presión.

3.2.11.1 Pantalla Principal.

Previo al inicio de los trabajos de hincado todos los perfiles de acero HZ y AZ después de concluir su proceso de protección anticorrosión, el equipo de topografía realizará la tarea de marcar con pintura el eje de cada elemento y longitudinalmente en el lugar más apropiado marcara con pintura cada 0.05 m, cada 0.50 m y cada 1.00 m, indicando con números la longitud del elemento con la finalidad de que durante el proceso de hincado el Ingeniero responsable de los trabajos, pueda llevar el control del hincado conforme vaya bajando y el número de golpes con los que va penetrando en el terreno, documentándose todo el proceso de cada elemento.

Figura 3.12 Equipo de Hinca.



Nota: Imagen ilustrativo

En lo que respecta a la maquinaria que va ser utilizada para el hincado, como es el chalan de 1,200 ton, el remolcador, la grúa de orugas con pluma estructural LS-518, la perforadora rotaria con botes y brocas, el vibrohincador o martillo para hincado D-62, lanchas con motor fuera de borda, planta de soldar, escantillón que fue fabricado con las dimensiones adecuadas con sus sancos , equipo de corte oxi-acetileno, se revisó mecánicamente para que antes de que se inicien las actividades de hincado, contando con todo el personal de operación, maniobristas y buzos equipados para el buen funcionamiento durante la operación de la maquinaria.

La cuadrilla de topografía destinada para los trabajos de hincado realizo con anticipación la colocación de todas las referencias necesarias en tierra y antes de iniciar el hincado reviso que su equipo de topografía, nivel automático y estación total se encuentren en condiciones óptimas, probando los equipos de comunicación con el personal de hincado y operadores.

El ingeniero responsable de los trabajos de hincado deberá realizar la revisión de todos los preparativos, y que los perfiles de acero HZ y tablestacas AZ estén listos para su instalación, le informará a la supervisión de la obra para que verifique y autorice el inicio de los trabajos de

hincado de las secciones de acero que conforman el muro combinado de la pantalla principal. Con el apoyo de una grúa con pluma telescópica y un tractocamión con dolly, serán cargados los perfiles de acero y serán trasladados al muelle provisional que se construyó para estos trabajos, donde el chalan con capacidad de 1,200 ton, que contará con una grúa sobre su cubierta, serán cargados los perfiles de acero al chalan que van a ser trasladados al sitio de hincado indicado en proyecto. El remolcador que forma parte del equipo de hincado trasladará al chalan, cargado con todo su equipo de hincado y los perfiles de acero, hasta el sitio donde se iniciaran las actividades de hincado.

Una vez que la supervisión de la obra, realizo la revisión de los trazos y niveles, los materiales, equipo de hincado, autorizará el inicio del hincado, el remolcador deberá posicionar el chalan en el área de hincado, una vez posicionado la grúa que esta sobre el chalan bajará el escantillón y se posicionará con la ayuda de equipo topográfico, ya colocado en su posición se fijaran los sancos.

Dadas las condiciones de dureza de los estratos de arena compacta, se estima conveniente el empleo del procedimiento de perforación previa e hincado con martillo hidráulico, recomendándose realizar tres perforaciones continuas donde se localizarán los perfiles HZ, y antes de hincar la tercera pieza realizar otras tres perforaciones con la finalidad de que se protejan los perfiles antes de realizar la perforación.

La perforadora será instalada en la grúa, con un bote de 1.00 m de diámetro, esta será bajada con la ayuda de un barretón en los puntos marcados en el escantillón, y se inicia la perforación y la extracción del material. Durante todo el procedimiento de perforación, será controlado los niveles y el avance de perforación con la ayuda del equipo de topografía. La perforación será detenida 3.00 m antes del nivel de desplante de la sección HZ indicado en los planos del proyecto.

Una vez finalizada la tarea de perforación de las secciones HZ, será retirado el bote de perforación del barretón y se posicionará la grúa con la perforadora en donde se ejecutar la perforación de la tablestaca AZ, montando el bote de 1.60 m de diámetro, iniciando la perforación para la tablestaca entendiendo que por ser un elemento de menor longitud el nivel de desplante de proyecto está más arriba que el de las secciones HZ, dicha perforación se detendrá 3.00 m antes de llegar a la cota de proyecto.

Es importante comentar que el material producto de las perforaciones por ser material de características arenosas, este podrá ser depositado por el equipo de perforación a un lado de las perforaciones debido a que no altera las condiciones de la superficie marina. Sin embargo, en caso de que el resolutivo de impacto ambiental indicará que el material debe ser retirado del sitio, este se extraerá se colocara en la cubierta del chalan y se retirara hasta el sitio de disposición final.

Después de concluir la perforación se desmonta el equipo de perforación de la grúa, y con ayuda de los maniobristas se sujetará la sección de acero tipo HZ, la grúa izará el elemento y la introducirá en el escantillón y a su vez en la perforación realizada, una vez en el interior se verificará la verticalidad del elemento, para proceder a la hinca. La grúa toma el martillo hidráulico para hincado y se montará el capuchón del martillo en la cabeza de la sección HZ, se revisará la verticalidad del martillo y se procederá al hincado. Durante todo el procedimiento de hinca se deberá revisar el número de golpes del matillo y el avance de la sección HZ.

Desde el primer golpe se observará la longitud que va penetrando la sección HZ en el terreno, llevando el control de la penetración de acuerdo con el número de golpes del martillo. Cuando se aproxima al nivel de desplante indicando en los planos de proyecto, se verificará el rebote del martillo y el número de golpes, para determinar que la sección llegó al estrato resistente. En el momento en que suspende el hincado se retira el martillo y verificará que los conectores de la sección HZ no registren ningún daño. Una vez colocados varias de las secciones HZ, se procederá al izaje de la tablestaca AZ con la ayuda de la grúa y la guía se engarzarán los candados de unión con la sección HZ y se bajará hasta el fondo de su perforación, se liberará la tablestaca y será montado de nueva cuenta el martillo en la grúa y se iniciará el hincado con el martillo, llevando el control del número de golpes con forme va penetrando la tablestaca en el terreno. Al igual que el procedimiento de hinca de la sección HZ, también se verificará el número de golpes y la penetración del elemento AZ.

La secuencia de trabajo descrita anteriormente para este sistema de muro combinado es repetitiva hasta terminar de hincar las secciones HZ y AZ, tomando en consideración que siempre se debe dejar una perforación sin hincar para evitar que se dañen los conectores o los perfiles del proyecto.

Es importante comentar que dada la gran cantidad de secciones de acero HZ y AZ por hincar, se recomienda sean considerados dos equipos de hincado partiendo de un punto medio del eje del muro, el primer equipo iniciará las actividades de hinca y una vez que se haya terminado una secuencia de hinca, el segundo equipo iniciará los trabajos en el sentido opuesto, con el objetivo que no se interfieran ambos equipos.

Se debe contemplar que la empresa contratista, responsable de los trabajos, cuente con los recursos necesarios y experiencia para cumplir con el programa de trabajo. Asimismo, se debe tener en consideración las temporadas de mal tiempo asociadas a lluvias y huracanes, ya que estos pueden influir en el avance de los trabajos y en el programa de obra.

En los casos en que se necesiten chorros de agua, se requiere un mínimo de dos. El volumen y la presión de agua en las boquillas deberá ser tal que erosione libremente el material adyacente.

Fuente: Elaboración propia, 2026

Los elementos metálicos del tablestacado se hincarán con la elevación, penetración y capacidad de carga indicada en el proyecto. El hincado de cada elemento se hará en forma continua hasta alcanzar la profundidad fijada en el proyecto, en caso de así requerirlo, el contratista podrá realizar una perforación previa para el hincado de los elementos metálicos utilizando el método que considere más conveniente, dicha perforación deberá quedar incluida en su costo de hincado. Es importante que se considere que la perforación que se realice permita que el elemento metálico se hinque de manera justa, ya que es inadmisible que quedara flojo.

En el manejo e hincado de los elementos metálicos del muro combinado el Contratista debe cuidar que estos no sufran ningún daño y si esto pasara, los deberá reparar por su cuenta y cargo.

Antes del hincado, el extremo (cabeza) de los elementos metálicos del muro combinado se deberá proteger adecuadamente para que no sufran deterioro por el uso del martillo o vibrador.

Los sitios donde serán hincadas las tablestacas se ubicarán de acuerdo con lo establecido en el proyecto. Asimismo, el hincado de las tablestacas se efectuará de manera que se garantice su integridad estructural, en forma tal que el elemento pueda cumplir adecuadamente con su cometido para el que fue diseñado.

Las tablestacas se marcarán a una separación máxima de un (1) metro a todo lo largo, con el fin de determinar con facilidad el número de golpes necesarios para cada metro de hincado y la posición relativa a las tablestacas vecinas.

Tanto la tablestaca como la resbaladera del martillo, se colocarán en posición perfectamente vertical, corrigiendo la posición de la grúa hasta lograrlo.

Para la prevención de daños de la tablestaca durante su hincado se tomará en cuenta lo siguiente:

- Se usará un material de amortiguamiento adecuado entre el gorro de acero del martillo y la cabeza de la tablestaca.
- Para reducir los esfuerzos durante el hincado y obtener la energía necesaria, se usará un pistón pesado con baja velocidad de impacto, es decir de carrera corta, en vez de un pistón ligero con alta velocidad de impacto, es decir de carrera larga.
- A fin de evitar una distribución no uniforme de las fuerzas de impacto, la cabeza de la tablestaca deberá ser perpendicular al eje del matillo.
- Cuando se encuentren suelos de baja resistencia, se reducirá la le velocidad del pistón o la carrera al principio del hincado.

Para asegurar la unión entre las tablestacas, se verificará su verticalidad a lo largo de la junta a medida que avanza el hincado.

Durante el hincado de las tablestacas se llevará un registro que contenga como mínimo:

- Información general como fecha, condiciones atmosféricas e identificación de la tablestaca.
- Localización precisa de la tablestaca y su número.
- Verticalidad de las tablestacas verificada a intervalos regulares durante su hincado.
- Estabilidad y alineación de las resbaladeras y guías.
- Número de golpes por unidad de longitud.
- Desplazamientos de la tablestaca bajo los golpes a distintas profundidades.
- Posición y calidad de las uniones.
- Localización, hora y duración de cualquier interrupción durante el hincado.
- Desplazamientos permanentes y golpes por centímetro para el hincado final.
- Elevación del terreno natural, de la pinta de la tablestaca y del descabece.
- Cualquier comportamiento errático o no usual de la tablestaca, anotando la hora y elevación correspondiente a la punta.
- Posible emersión de las tablestacas adyacentes.

Para que la construcción del tablestacado se considere terminada y sea aceptada, con base en el control de calidad que ejecute el Contratista, se comprará:

- Calidad del material
- Ubicación, alineamiento y dimensiones.
  - Que la dimensión en el sentido largo de la sección transversal haya sido la establecida en el proyecto o aprobado por la Entidad, con una tolerancia de más menos un (1) milímetro.
  - Que el espesor haya sido el establecido en el proyecto, con una tolerancia de más menos tres (3) milímetros.
  - Que la longitud de la tablestaca haya sido la establecida en el proyecto con aprobada por la Entidad, con una tolerancia de más menos cuatro centésimas (0.004) de la longitud de proyecto.
  - Que la desviación respecto al eje longitudinal teórico de la tablestaca, previamente a su hincado, no haya sido mayor de una centésima (0.01) de su longitud.
  - Que la posición final del extremo superior de la tablestaca no haya variado respecto a la de proyecto en más de un (1) centímetro en el sentido horizontal y diez (10) en el sentido vertical.
  - Que una vez hecha la excavación, la inclinación de la tablestaca en su parte visible no haya presentado una desviación mayor a un (1) centímetro por metro respecto a lo establecido en el proyecto o aprobado por la Entidad.

- Calidad del material

3.2.11.2 Pantalla Secundaria.

Una vez finalizada la instalación del muro principal, se procede a la ejecución de las actividades de dragado en la zona donde se desarrollará el sistema de anclaje. El dragado tiene como objetivo retirar los sedimentos existentes hasta alcanzar las cotas definidas en el proyecto, permitiendo posteriormente la colocación controlada de rellenos que funcionarán como masa de reacción para el sistema de anclaje.

De manera paralela al avance de estos rellenos se procede a la instalación del tablestacado secundario tipo AZ, el cual funciona como elemento de anclaje del muro principal. Este tablestacado secundario se hinca detrás del muro principal. La instalación de estas tablestacas se realiza mediante vibrador hidráulico desde la plataforma flotante, cuidando que su alineación y profundidad de hinca correspondan con lo especificado en el diseño.

A medida que se hinca el tablestacado secundario, se realiza simultáneamente la colocación de rellenos provenientes del dragado, formando progresivamente el terraplén o masa de suelo que proporcionará resistencia al sistema de anclaje. Estos rellenos se colocan en capas controladas y se distribuyen mediante equipo adecuado para garantizar una adecuada conformación del terreno y evitar asentamientos diferenciales.

Posteriormente se procede a la instalación de los elementos de conexión (tensores) entre el muro principal y el tablestacado secundario, se fijarán al muro principal a través de vigas de reparto o wales metálicos. Estos tirantes se extienden hasta el tablestacado secundario, donde se anclan mediante dispositivos estructurales de acero, diseñados para transmitir las cargas de tracción. Una vez instalados, los tirantes se someten a un proceso de tensado controlado mediante gatos hidráulicos, aplicando la carga especificada en el diseño para garantizar que el sistema trabaje adecuadamente frente a los empujes del terreno y del agua.

Finalmente, se realizan verificaciones de alineación, desplazamientos y tensión en los anclajes, asegurando que el muro combinado HZ–AZ y el sistema de anclaje con tablestaca secundaria funcionen de manera integrada y proporcionen la estabilidad requerida para las etapas posteriores del proyecto. Este procedimiento permite ejecutar la obra en condiciones subacuáticas, optimizando la instalación mediante perforación previa y aprovechando los materiales producto del dragado para conformar el sistema de anclaje del tablestacado.

3.2.11.3 Instalación de Tensores y Herrajes.

La instalación de los tensores y herrajes deberá realizarse una vez que se haya instalado el muro formado por la tablestaca principal, de acuerdo con lo indicado en los planos de proyecto.

Los procedimientos de ejecución y los sistemas de control que se adopten para la instalación de los tensores y herrajes deben asegurar lo siguiente:

- El acceso y la evolución de las máquinas. Se debe disponer del espacio necesario para realizar las maniobras de descarga, elevación y colocación de los perfiles.
- La correcta situación en planta de los perfiles y tensores.
- La correcta colocación de los perfiles para los anclajes.

Figura 3.15 Instalación de Tensores.

Nota: Imagen ilustrativo

Los tensores con los que se anclan las tablestacas, la conexión de estas, su puesta en tensión y el relleno de tierra en el que quedan enterrados, constituyen la parte más delicada de la instalación de la tablestaca, por lo tanto, deben ser ejecutados con estricta observancia de las especificaciones y de los procedimientos establecidos por el fabricante.

Considerando lo anterior, antes de iniciar la compactación de los terrenos, los anclajes requieren una tensión entre el 5% y el 10% de la tensión nominal para controlar las deformaciones.

Se pondrá especial atención en la elección del material de relleno en contacto con los anclajes y en su forma de ejecución para no producir daños en ellos.

Todos los trabajos que se realicen para la instalación de los tensores deberán cumplir con las normas, dimensiones y demás características estipuladas en los planos de proyecto, así como las recomendaciones del fabricante.

Todos los materiales que se utilicen para la instalación de los tensores y herrajes deben ser nuevos y de primera calidad.

La unión de las ménsulas de placa de acero se realizará mediante soldadura. Los extremos de las ménsulas y la zona de la tablestaca en donde se soldará deberán ser previamente limpiados retirando de ellos grasa, aceite, herrumbre y cualquier otra impureza. Las juntas de soldadura deberán ser esmeriladas y reparadas, cuando esto se requiera, verificando que en su acabado no presenten grietas. Los trabajos de soldadura deberán ser ejecutados por personal calificado y con experiencia.

La instalación de los perfiles tipo canal o la viga I de acero comprende el conjunto de todas las maniobras y trabajos que sean necesarios para la debida colocación de los perfiles sobre las ménsulas, previa unión de estas mediante junta soldada. Cada perfil se alineará con el ya instalado.

El alineamiento del perfil será hecho en tal forma que no sea visible ninguna desviación angular entre dos perfiles consecutivos. Asimismo, la colocación de los tensores, herrajes y perfiles, deberán ser colocados dentro de las líneas y niveles de proyecto.

Una vez instalados los tensores, perfiles y herrajes, con el alineamiento de proyecto, deberán ser ajustados de manera definitiva.

Asimismo, el contratista deberá seguir las recomendaciones que realice el fabricante en lo relacionado al transporte y colocación de las piezas.

3.2.12 Fabricación de Cabezal.

Una vez que se haya terminado de instalar el tablestacado de la pantalla principal y secundaria, y estas se encuentren unidas con los tensores, se procederá a realizar la construcción del cabezal en la parte superior del tablestacado.

El cabezal estará fabricado de concreto será resistente a la acción de sulfatos y tendrá la resistencia de proyecto y para su fabricación y colocación deberá cumplir con las especificaciones físicas y químicas de acuerdo con las Normas Oficiales vigentes y aplicables. El concreto tendrá una resistencia a la compresión f'c = 350 kg/cm^2, a los 28 días de duración.

Asimismo, el acero de refuerzo se ajustará a la especificación ASTM-A-615, grado 60 (Fy = 4,200 kg/cm^2) límite de fluencia o límite elástico. El material debe llegar a la obra exento de oxidación, libre de aceite, grasa o alguna otra sustancia perjudicial y sin quiebres, hojeaduras, ni deformidades de la sección, en donde no haya posibilidad de contaminación con tierra, lodo, aceite, grasa o alguna otra sustancia nociva.

Cuando haya necesidad de descargar sobre el terreno, se colocarán polines o plataformas a fin de que el material descanse en ellos y no sufra alteraciones en su longitud original.

Si bien el procedimiento constructivo de la hinca de la tablestaca no es desconocido en México y se cuenta con empresas con experiencia en la realización de este tipo de trabajos. No es un trabajo sencillo, ya que hay que considerar diversos factores siendo estos los siguientes:

- De acuerdo con mecánica de suelos, el estrato resistente se encuentra a poca profundidad, aproximadamente a 10 m en promedio, este hecho puede complicar los trabajos de hinca.

  Lo anterior pone de manifiesto que para la hinca de la tablestaca sea necesario complementar el procedimiento constructivo con chiflón y/o perforación previa.

- Los trabajos de hinca deben iniciar a la par con los trabajos de dragado de las arenas o si es posible, antes de que inicie el dragado de la capa de arena, con el objetivo de tener un avance de la estructura de contención de rellenos.

  Es importante que la programación de los trabajos de hinca de la tablestaca y el dragado se integren mutuamente, para evitar retrasos en la obra.

3.3 Proceso Constructivo de los Viaductos Vehiculares, Ferroviario y Urbanización

El desarrollo de infraestructura asociada a la ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán implica la ejecución de un conjunto de obras de gran escala que incluyen vialidades a nivel, viaductos elevados carreteros, viaductos ferroviarios y obras de urbanización. Estas intervenciones se localizan en un entorno lagunar caracterizado por suelos blandos, alta saturación, interacción hidráulica y sensibilidad ambiental, lo que introduce condiciones técnicas particularmente complejas.

En la etapa actual, donde los proyectos se encuentran a nivel conceptual y no se dispone aún de un proyecto ejecutivo detallado, resulta necesario establecer una justificación técnica del proceso constructivo general que permita demostrar la viabilidad de ejecución de las obras, definir criterios preliminares de construcción y sustentar estimaciones de costo, tiempo y recursos.

3.3.1 Condiciones del sitio y retos constructivos.

La Laguna de Cuyutlán presenta un sistema de depósitos lacustres con baja capacidad portante, alta compresibilidad y presencia permanente de agua superficial o niveles freáticos someros. Estas condiciones hacen inviable, en muchos casos, la solución tradicional mediante terraplenes convencionales de gran altura, debido al riesgo de asentamientos diferenciales y fallas de estabilidad.

Por esta razón, la solución constructiva en este tipo de entorno tiende a privilegiar estructuras elevadas, cimentaciones profundas y sistemas constructivos que reduzcan la transmisión de cargas al terreno natural. Asimismo, la presencia de cuerpos de agua obliga a incorporar metodologías propias de obra marítima, incluyendo el uso de plataformas flotantes, accesos provisionales y equipos especializados.

3.3.2 Enfoque metodológico del proceso constructivo.

El proceso constructivo general para este tipo de proyectos debe plantearse como una estrategia integrada que permita ejecutar simultáneamente diferentes tipos de obra, bajo un esquema de frentes múltiples y con una secuencia lógica que optimice tiempos y reduzca interferencias.

Dado que el proyecto se encuentra en fase conceptual, la selección de métodos constructivos se basa en la experiencia en obras similares, en las condiciones conocidas del sitio y en criterios conservadores que permitan absorber la incertidumbre asociada a la falta de información detallada.

El enfoque adoptado considera la coexistencia de tres grandes sistemas constructivos: obras sobre terreno natural o mejorado, estructuras elevadas soportadas por cimentaciones profundas y obras de urbanización vinculadas a la operación portuaria.

3.3.2.1 Proceso constructivo para vialidades a nivel

El desarrollo de vialidades a nivel dentro del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán debe abordarse como un proceso técnico altamente condicionado por la naturaleza del terreno, el régimen hidráulico del sitio y las exigencias operativas propias de un entorno portuario. A diferencia de una vialidad convencional en suelo firme, en este caso el proceso constructivo se encuentra determinado por la necesidad de

transformar un terreno de baja capacidad portante, altamente compresible y frecuentemente saturado, en una plataforma estructural capaz de soportar cargas intensivas y repetitivas asociadas al tránsito pesado.

La justificación técnica del proceso constructivo inicia con el reconocimiento de que el terreno natural no constituye, en su estado original, un soporte adecuado para la construcción directa de una vialidad. En consecuencia, la primera fase debe orientarse a la habilitación del sitio y a la creación de condiciones mínimas de acceso y operación. Esta etapa incluye la apertura de caminos provisionales, la estabilización inicial de rutas de maquinaria y la delimitación de los ejes de trazo, lo cual permite organizar los frentes de trabajo y establecer una secuencia lógica de ejecución. En un entorno lagunar, esta habilitación puede implicar la colocación de material granular temporal, el uso de geosintéticos para mejorar la capacidad de tránsito o incluso la construcción de terraplenes provisionales que sirvan como plataformas de trabajo.

Una vez establecido el acceso operativo, el proceso constructivo continúa con la preparación del terreno, la cual implica la remoción de materiales inadecuados, tales como capas orgánicas, sedimentos blandos superficiales o rellenos no controlados. Este procedimiento no debe entenderse únicamente como una actividad de limpieza, sino como una intervención dirigida a eliminar elementos que comprometan la estabilidad de la futura estructura del pavimento. En la Laguna de Cuyutlán, esta etapa puede presentar variaciones importantes en función de la profundidad de los estratos blandos y de la presencia de agua superficial, lo que obliga a adaptar las técnicas de despalme y manejo de materiales.

El elemento central del proceso constructivo es el acondicionamiento geotécnico del terreno. En proyectos de este tipo, la simple colocación de un terraplén sobre el suelo natural genera incrementos de carga que inducen asentamientos diferidos, lo cual puede traducirse en deformaciones excesivas de la vialidad, pérdida de servicio y costos elevados de mantenimiento. Por ello, la justificación técnica del proceso constructivo contempla la implementación de técnicas de mejoramiento del suelo desde las etapas iniciales.

Entre las estrategias conceptualmente viables se encuentra la aplicación de precarga, mediante la cual se induce de manera controlada la consolidación del terreno antes de la construcción definitiva de la vialidad. Este proceso puede complementarse con la instalación de drenes verticales prefabricados, que aceleran la disipación de presiones de poro y reducen los tiempos de consolidación. En otros casos, puede considerarse el uso de geosintéticos, como geotextiles de separación o geomallas de refuerzo, que permiten mejorar la distribución de cargas y aumentar la estabilidad del terraplén. Cuando las condiciones lo requieran, también es posible contemplar la sustitución parcial del material blando o la inclusión de elementos de mejora más rígidos, dependiendo de la capacidad portante requerida y de los asentamientos admisibles.

Con el terreno debidamente acondicionado, se procede a la construcción del terraplén o plataforma estructural de la vialidad. Este proceso debe ejecutarse mediante la colocación

controlada de materiales seleccionados, en capas sucesivas, cuidando que cada una de ellas cumpla con los parámetros de espesor, humedad y compactación establecidos en la ingeniería preliminar. La justificación de este procedimiento radica en la necesidad de generar una estructura homogénea y estable que permita transmitir las cargas hacia el terreno de manera controlada. En suelos blandos, es frecuente que esta etapa se desarrolle de forma progresiva, con incrementos de carga escalonados y periodos de espera intermedios que permitan la disipación de presiones y la reducción de asentamientos posteriores.

Durante la conformación del terraplén, resulta fundamental integrar el sistema de drenaje, tanto superficial como subterráneo. En un entorno como la Laguna de Cuyutlán, donde el agua constituye un factor permanente, el drenaje no puede considerarse un elemento secundario, sino un componente estructural del sistema vial. La construcción de cunetas, drenes longitudinales, subdrenes y obras de cruce debe ejecutarse de manera coordinada con el avance del terraplén, asegurando que el agua no se acumule dentro de la estructura ni debilite las capas de soporte. La correcta gestión del agua contribuye de manera directa a la durabilidad de la vialidad y a la estabilidad del sistema en su conjunto.

Una vez alcanzada la cota de proyecto y estabilizada la plataforma, se inicia la construcción de la estructura de pavimento. En el contexto portuario, las vialidades están sujetas a cargas de tránsito significativamente mayores que las de una carretera convencional, debido a la circulación de tractocamiones, equipos de carga y vehículos especializados. Por esta razón, la estructura de pavimento debe diseñarse con un enfoque robusto, que permita resistir tanto cargas estáticas como dinámicas.

El proceso constructivo de la estructura de pavimento implica la colocación de capas de subbase y base, las cuales pueden estar constituidas por materiales granulares o estabilizados, dependiendo de los requerimientos de diseño. Estas capas cumplen la función de distribuir las cargas y proporcionar una superficie adecuada para la capa de rodamiento. En función de las condiciones del proyecto, la capa final puede resolverse mediante pavimento asfáltico o concreto hidráulico, siendo este último frecuentemente preferido en zonas de operación portuaria debido a su mayor resistencia a deformaciones y a cargas repetitivas.

En paralelo a la construcción de la estructura de pavimento, deben ejecutarse los elementos complementarios de la vialidad, tales como guarniciones, banquetas, obras de protección, señalamiento horizontal y vertical, alumbrado público y dispositivos de seguridad. Estos elementos no solo contribuyen a la funcionalidad y seguridad de la vialidad, sino que también forman parte integral de su desempeño operativo.

Desde el punto de vista constructivo, es importante considerar que las vialidades a nivel en un entorno portuario no se ejecutan de manera aislada, sino en estrecha coordinación con las obras de urbanización, redes de servicios y edificaciones. Esto implica que la secuencia

constructiva debe planearse de tal forma que las actividades subterráneas se completen antes de la colocación de las capas finales del pavimento, evitando interferencias y retrabajos.

Otro aspecto relevante en la justificación técnica del proceso constructivo es el control de calidad. Dado que el desempeño de la vialidad depende en gran medida de la correcta ejecución de cada una de sus capas, es indispensable implementar un sistema de control que incluya pruebas de compactación, verificación de materiales, control de espesores y monitoreo de asentamientos. En un proyecto conceptual, este requerimiento se establece como un principio rector, aun cuando los procedimientos específicos se definan en etapas posteriores.

Finalmente, debe señalarse que la construcción de vialidades a nivel en la Laguna de Cuyutlán requiere una visión de largo plazo, en la cual se consideren no solo las condiciones iniciales del terreno, sino también su evolución en el tiempo. Los asentamientos diferidos, la variabilidad del nivel freático y las condiciones ambientales pueden afectar el desempeño de la infraestructura si no se incorporan desde el inicio en la estrategia constructiva. Por ello, la justificación técnica del proceso constructivo se fundamenta en la adopción de métodos que permitan anticipar y controlar estos efectos, garantizando la funcionalidad y durabilidad de la vialidad dentro del sistema portuario.

En este contexto, el proceso constructivo propuesto no debe entenderse como una secuencia rígida, sino como un esquema técnico adaptable, que puede ajustarse conforme se disponga de información más detallada del sitio. Sin embargo, aún en fase conceptual, es posible establecer con claridad que la clave para la construcción exitosa de vialidades a nivel en la Laguna de Cuyutlán radica en la adecuada interacción entre mejoramiento del terreno, control del agua, construcción progresiva de terraplenes y ejecución rigurosa de la estructura de pavimento.

3.3.2.2 Proceso constructivo para viaductos elevados carreteros

El desarrollo de viaductos elevados carreteros dentro del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán responde a la necesidad de resolver, de manera estructuralmente eficiente y geotécnicamente viable, la interacción entre infraestructura vial y un entorno caracterizado por suelos blandos, alta saturación y presencia permanente de cuerpos de agua. En este contexto, la solución mediante estructuras elevadas no constituye únicamente una alternativa constructiva, sino una respuesta técnica obligada para garantizar la funcionalidad, durabilidad y seguridad de la infraestructura en el largo plazo.

La justificación técnica del proceso constructivo de viaductos elevados se fundamenta en la necesidad de transferir las cargas de la superestructura hacia estratos profundos con capacidad portante adecuada, evitando así los problemas asociados a asentamientos diferenciales y pérdida de servicio que serían inevitables en soluciones a nivel. Bajo este principio, el proceso constructivo se organiza en una secuencia lógica que integra la ejecución de cimentaciones profundas, la

construcción de la subestructura, el montaje de la superestructura y la conformación de la losa de rodamiento y elementos complementarios.

El proceso constructivo inicia con la habilitación del frente de trabajo, lo cual en un entorno lagunar implica una combinación de accesos provisionales, plataformas de trabajo y, en muchos casos, el uso de pontonas o sistemas flotantes. La elección del esquema de acceso depende de la profundidad del agua, la estabilidad del terreno superficial y la longitud del tramo a ejecutar. En zonas someras o parcialmente consolidadas, puede optarse por caminos temporales reforzados con materiales granulares y geosintéticos, mientras que en zonas más profundas resulta más eficiente operar con equipos montados sobre pontonas estabilizadas. Esta etapa inicial es determinante para la productividad del proyecto, ya que condiciona la movilidad de equipos pesados, el suministro de materiales y la continuidad de los frentes de trabajo.

Una vez garantizadas las condiciones de acceso, el proceso constructivo avanza hacia la ejecución de las cimentaciones profundas, que constituyen el elemento estructural más crítico del sistema. En ausencia de un proyecto ejecutivo, la selección preliminar del tipo de cimentación se basa en la experiencia en obras similares en la región, donde el uso de pilas coladas en sitio mediante perforación rotatoria ha demostrado ser una solución eficaz. Estas pilas se ejecutan mediante equipos especializados capaces de perforar el terreno hasta alcanzar estratos competentes, utilizando sistemas de estabilización como lodos bentoníticos o entubados temporales para mantener la integridad del taladro en condiciones saturadas.

El procedimiento constructivo de las pilas implica la perforación controlada del terreno, la limpieza del fondo del taladro, la colocación de la jaula de acero de refuerzo y el colado del concreto mediante el método tremie, que permite desplazar el agua y evitar la segregación del material. La calidad de esta etapa es fundamental, ya que cualquier deficiencia en la ejecución puede comprometer la capacidad estructural de toda la superestructura. En proyectos de gran longitud, como los asociados a la ampliación portuaria, es habitual que múltiples equipos de perforación operen de manera simultánea, permitiendo avanzar en varios frentes y optimizar los tiempos de ejecución.

Concluida la etapa de cimentación, se procede a la construcción de la subestructura, que incluye elementos como cabezales, capiteles y columnas. Estos componentes tienen la función de transferir las cargas desde la superestructura hacia las pilas y de proporcionar los apoyos necesarios para el montaje de las vigas o trabes. Su ejecución se realiza mediante sistemas de cimbrado y colado de concreto en sitio, cuidando la correcta alineación y nivelación de los elementos, ya que cualquier desviación puede generar problemas durante el montaje posterior.

La siguiente fase corresponde al montaje de la superestructura, la cual puede resolverse mediante distintos sistemas estructurales, siendo los más comunes las trabes prefabricadas de concreto presforzado o estructuras metálicas. En el contexto de una etapa conceptual, la selección de trabes prefabricadas suele ser técnicamente justificable debido a su rapidez de ejecución,

calidad controlada en planta y reducción de trabajos en sitio. Estas trabes son fabricadas en instalaciones especializadas, transportadas al sitio mediante equipos de carga pesada y montadas en su posición definitiva utilizando grúas de gran capacidad o sistemas de lanzamiento.

El montaje de la superestructura representa uno de los momentos más críticos del proceso constructivo, ya que involucra maniobras de alto riesgo, coordinación precisa entre equipos y control estricto de las condiciones de estabilidad. En zonas sobre agua, estas maniobras pueden realizarse desde pontonas equipadas con grúas, lo que requiere considerar factores adicionales como el oleaje, la corriente y la capacidad de posicionamiento de las embarcaciones.

Una vez colocadas las trabes, se procede a la construcción de la losa de rodamiento, que integra la superestructura en un sistema continuo y proporciona la superficie de circulación vehicular. Esta losa se ejecuta mediante el colado de concreto sobre formaletas instaladas entre las vigas, incorporando acero de refuerzo y, en su caso, sistemas de presfuerzo adicionales. El diseño preliminar de esta losa debe considerar las cargas vehiculares, la distribución de esfuerzos y las condiciones de durabilidad en ambiente marino.

Posteriormente, se ejecutan los elementos complementarios del viaducto, incluyendo parapetos, barreras de seguridad, juntas de expansión, sistemas de drenaje superficial y dispositivos de señalización. El drenaje del viaducto es particularmente relevante, ya que evita la acumulación de agua sobre la superficie de rodamiento y protege los elementos estructurales de la infiltración.

Desde el punto de vista constructivo, es fundamental que la ejecución de los viaductos se integre de manera coordinada con las vialidades a nivel, las obras de urbanización y las conexiones con otras infraestructuras. Esto implica que las rampas de acceso, las transiciones entre estructuras y las intersecciones deben planearse desde etapas tempranas, aun en ausencia de un proyecto ejecutivo detallado.

La justificación técnica del proceso constructivo también debe considerar aspectos de durabilidad y mantenimiento. En un entorno como la Laguna de Cuyutlán, los materiales están expuestos a condiciones agresivas, por lo que es necesario prever el uso de concretos diseñados para ambientes marinos, recubrimientos adecuados del acero de refuerzo, sistemas de protección anticorrosiva y detalles constructivos que minimicen la acumulación de humedad.

Finalmente, es importante destacar que, debido al carácter conceptual del proyecto, el proceso constructivo descrito debe entenderse como un marco de referencia técnico adaptable. La secuencia y los métodos podrán ajustarse conforme se disponga de información más detallada, particularmente en lo que respecta a la geotecnia del sitio y a las especificaciones estructurales definitivas. Sin embargo, aun en esta etapa, es posible afirmar que la construcción de viaductos elevados mediante cimentaciones profundas, subestructura de concreto y superestructura

prefabricada constituye una solución técnica coherente y ampliamente probada para las condiciones de la Laguna de Cuyutlán.

En este sentido, el proceso constructivo propuesto no solo garantiza la viabilidad de la obra, sino que establece las bases para su desarrollo eficiente, seguro y durable dentro del sistema integral de ampliación portuaria.

3.3.2.3 Proceso constructivo para viaducto ferroviario

El desarrollo de un viaducto ferroviario dentro del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán responde a requerimientos técnicos más exigentes que los de una infraestructura carretera, debido principalmente a la naturaleza de las cargas ferroviarias, la repetitividad de las solicitaciones dinámicas y las tolerancias geométricas estrictas que exige la operación segura de trenes de carga pesada. En este contexto, el proceso constructivo debe justificarse no solo en términos de viabilidad estructural, sino también en función de la precisión, durabilidad y estabilidad a largo plazo de la vía.

Desde una perspectiva conceptual, el viaducto ferroviario se concibe como un sistema estructural continuo cuya función es transmitir las cargas del tren hacia elementos de cimentación profunda, evitando la interacción directa con suelos blandos y altamente compresibles característicos de la Laguna de Cuyutlán. Esta condición hace que, al igual que en los viaductos carreteros, la solución elevada sea la alternativa técnica más adecuada, pero con requerimientos adicionales en cuanto a control de deformaciones y alineamiento.

El proceso constructivo inicia con la habilitación del sitio, que en un entorno lagunar implica la definición de accesos provisionales, plataformas de trabajo y, en muchos casos, el uso de pontonas o sistemas flotantes para la operación de equipos. A diferencia de las vialidades a nivel, donde el terreno puede ser acondicionado progresivamente, en el caso del viaducto ferroviario la construcción se apoya desde el inicio en sistemas que permitan operar de forma independiente del terreno superficial, reduciendo así la influencia de las condiciones geotécnicas adversas en la ejecución de la obra.

Una vez establecidas las condiciones de acceso, el proceso constructivo se centra en la ejecución de cimentaciones profundas, las cuales constituyen el elemento fundamental del sistema estructural. La selección preliminar de pilas coladas en sitio mediante perforación rotatoria se justifica por su capacidad para adaptarse a condiciones de suelo saturado, su versatilidad en cuanto a diámetros y profundidades, y su comportamiento favorable frente a cargas verticales y horizontales. En el contexto ferroviario, estas pilas deben diseñarse no solo para soportar cargas estáticas elevadas, sino también para resistir efectos dinámicos, vibraciones y posibles solicitaciones laterales derivadas de frenado o aceleración de trenes.

El procedimiento constructivo de las pilas sigue una secuencia técnica que incluye la perforación del terreno mediante equipos especializados, la estabilización del taladro utilizando lodos o entubados, la limpieza del fondo para garantizar condiciones adecuadas de contacto y la colocación de la jaula de refuerzo. El colado del concreto se realiza mediante el método tremie, el cual permite ejecutar la pila en presencia de agua sin comprometer la calidad del material. La correcta ejecución de esta etapa es crítica, ya que cualquier defecto puede amplificarse en el comportamiento global de la estructura bajo cargas ferroviarias.

Concluida la cimentación, se procede a la construcción de la subestructura, compuesta por columnas, capiteles y cabezales. Estos elementos tienen la función de recibir las cargas de la superestructura y distribuirlas hacia las pilas de manera eficiente. En el caso de un viaducto ferroviario, el control geométrico durante esta etapa adquiere una relevancia especial, ya que pequeñas desviaciones en alineación o nivel pueden traducirse en problemas significativos durante la instalación de la vía. Por ello, el proceso constructivo debe incorporar sistemas de control topográfico de alta precisión desde las fases tempranas.

La superestructura del viaducto ferroviario puede resolverse mediante distintos sistemas, siendo común el uso de trabes prefabricadas de concreto presforzado o sistemas de losa continua. En una etapa conceptual, el uso de elementos prefabricados resulta técnicamente justificable debido a su calidad controlada, rapidez de montaje y reducción de trabajos en sitio, lo cual es particularmente ventajoso en entornos de difícil acceso como la laguna.

El montaje de las trabes se realiza mediante grúas de gran capacidad o sistemas de lanzamiento, dependiendo de las condiciones de acceso y de la longitud de los claros. En zonas sobre agua, estas maniobras pueden ejecutarse desde pontonas, lo que introduce variables adicionales relacionadas con la estabilidad y el control de posicionamiento. La precisión en el montaje es fundamental, ya que la superestructura debe cumplir con tolerancias estrictas para garantizar el correcto comportamiento de la vía.

Una vez instalada la superestructura, se procede a la conformación del sistema que soportará la vía ferroviaria. Este sistema puede incluir una losa de rodamiento sobre la cual se coloca la estructura de vía, o bien elementos prefabricados diseñados específicamente para este propósito. En el caso de sistemas con balasto, el proceso constructivo incluye la colocación de una capa de subbalasto que actúa como transición entre la estructura y el balasto, seguida de la distribución y nivelación del balasto propiamente dicho. Este material granular cumple la función de distribuir cargas, absorber vibraciones y permitir el ajuste fino de la geometría de la vía.

Sobre el balasto se colocan los durmientes, que pueden ser de concreto presforzado, seguidos de la instalación de los rieles y sistemas de fijación. Este proceso requiere el uso de equipos especializados capaces de garantizar la alineación, nivelación y perfil longitudinal de la vía dentro de tolerancias muy estrictas. Posteriormente, se realizan operaciones de bateo, alineación

y nivelación, que permiten ajustar la vía a su geometría final y asegurar condiciones adecuadas de rodadura.

En algunos casos, particularmente en viaductos elevados, puede optarse por sistemas de vía en placa o vía sin balasto, donde los rieles se fijan directamente sobre una losa de concreto. Este tipo de solución reduce el mantenimiento a largo plazo y mejora el control geométrico, aunque requiere una mayor precisión en la ejecución de la estructura base.

El proceso constructivo del viaducto ferroviario también incluye la instalación de elementos complementarios, como sistemas de drenaje, juntas de expansión, dispositivos de seguridad y, en su caso, canalizaciones para sistemas de señalización y control ferroviario. Estos elementos son esenciales para la operación segura del sistema y deben integrarse desde la fase constructiva.

Desde el punto de vista de integración del proyecto, el viaducto ferroviario debe coordinarse con las vialidades, las áreas de urbanización y las instalaciones portuarias, asegurando una conexión funcional con patios de maniobras, terminales y zonas logísticas. Esta integración implica que el proceso constructivo no puede desarrollarse de manera aislada, sino como parte de un sistema interdependiente donde la secuencia de ejecución debe minimizar interferencias y optimizar el uso de recursos.

La justificación técnica del proceso constructivo también debe considerar la durabilidad de la infraestructura. En un ambiente como la Laguna de Cuyutlán, los materiales están expuestos a condiciones agresivas, por lo que es necesario prever el uso de concretos diseñados para ambientes marinos, protección adecuada del acero y soluciones constructivas que minimicen la acumulación de humedad y la penetración de agentes corrosivos.

Finalmente, dado que el proyecto se encuentra en etapa conceptual, el proceso constructivo descrito debe entenderse como una base técnica adaptable. La secuencia y los métodos podrán ajustarse conforme se disponga de información más detallada, particularmente en lo que respecta a la geotecnia, las cargas de diseño y las especificaciones ferroviarias. No obstante, aun en esta etapa, es posible establecer que la construcción de un viaducto ferroviario mediante cimentaciones profundas, superestructura prefabricada y sistemas de vía de alta precisión constituye una solución técnica coherente y adecuada para las condiciones de la Laguna de Cuyutlán.

En este sentido, el proceso constructivo propuesto no solo permite garantizar la viabilidad de la obra, sino que establece las bases para una infraestructura ferroviaria segura, durable y compatible con las exigencias operativas del puerto ampliado.

3.3.2.4 Proceso constructivo para urbanización

El componente de urbanización dentro de un proyecto de ampliación portuaria en la Laguna de Cuyutlán debe entenderse como un sistema integral de transformación territorial que no se limita a la ejecución de vialidades internas o a la colocación de redes de servicios, sino que incluye también la conformación de plataformas operativas, patios de maniobras, áreas logísticas, obras de drenaje, infraestructura electromecánica, alumbrado, señalamiento, cercados, accesos controlados y edificaciones destinadas a la operación, administración, seguridad, inspección, mantenimiento y servicios generales. En un entorno de estas características, donde predominan suelos blandos, niveles freáticos someros, interacción hidráulica constante y condiciones químicas potencialmente agresivas para los materiales, el proceso constructivo de la urbanización debe justificarse a partir de una secuencia ordenada, técnicamente compatible con el comportamiento del subsuelo y suficientemente flexible para ajustarse al grado de definición propio de una etapa conceptual.

Desde una perspectiva general, la urbanización de una zona portuaria en terreno lagunar no puede abordarse como si se tratara de un desarrollo urbano convencional sobre suelo firme. La primera diferencia sustancial radica en que el terreno natural, por sí mismo, no ofrece condiciones inmediatas de soporte para pavimentos pesados, redes enterradas profundas o edificaciones con cargas concentradas. Por ello, el proceso constructivo debe comenzar con la definición y habilitación de áreas de trabajo, accesos provisionales, zonas de almacenamiento de materiales, bancos temporales de maniobra, patios de prefabricación cuando resulten necesarios y rutas internas para el tránsito de maquinaria. Esta fase preliminar tiene una importancia crítica, ya que la eficiencia de las etapas posteriores depende en gran medida de la logística inicial del sitio, particularmente cuando las obras conviven con cuerpos de agua, áreas inundables o superficies con baja capacidad portante.

Una vez habilitado el acceso operativo al polígono, la siguiente etapa corresponde a la preparación del terreno. Esta fase incluye la limpieza superficial, el retiro de vegetación, el despalme del material orgánico o inestable, la regularización inicial del terreno y, en su caso, la remoción de rellenos antrópicos inadecuados. En la Laguna de Cuyutlán, esta etapa debe ejecutarse con especial cuidado debido a la posible presencia de lodos blandos, costras salinas, materiales saturados y niveles variables de humedad. El objetivo técnico de esta preparación no es únicamente dejar libre la superficie, sino generar una condición de partida homogénea para las actividades de mejoramiento del subsuelo y construcción de plataformas.

El comportamiento del terreno constituye el factor rector del proceso constructivo de la urbanización. En consecuencia, antes de desarrollar plataformas definitivas, patios o edificaciones, resulta necesario definir una estrategia de acondicionamiento geotécnico del sitio. En proyectos de esta naturaleza, la solución puede contemplar distintas técnicas, cuya selección dependerá del espesor de los estratos compresibles, de los asentamientos tolerables y del uso previsto de cada área. Para zonas destinadas a vialidades internas ligeras, estacionamientos o áreas de servicio

secundarias, puede resultar suficiente una combinación de sustitución superficial de material, geotextiles de separación y capas de mejoramiento compactadas. En cambio, para patios de contenedores, vialidades de tránsito pesado, edificios operativos o estructuras con requerimientos de deformación reducida, normalmente se requiere una solución más robusta, basada en precarga, drenes verticales prefabricados, geomallas de refuerzo, columnas de grava, inclusiones rígidas o cimentaciones profundas, según corresponda.

La conformación de plataformas representa una de las actividades centrales del proceso de urbanización. Estas plataformas constituyen la base sobre la cual se desarrollarán tanto las áreas pavimentadas como las edificaciones y la infraestructura de servicio. Su construcción debe realizarse mediante la colocación controlada de material de relleno seleccionado, en capas sucesivas, con espesores, humedad y energía de compactación acordes con las especificaciones geotécnicas preliminares. En una etapa conceptual, la justificación técnica del procedimiento radica en que las plataformas permiten elevar la rasante de operación por encima de niveles de inundación, homogenizar las condiciones superficiales y distribuir de manera más favorable las cargas sobre el subsuelo. No obstante, cuando el terreno natural sea altamente compresible, la sola conformación de terraplenes o plataformas puede inducir asentamientos importantes, por lo que el proceso constructivo debe contemplar tiempos de espera, monitoreo topográfico y, en su caso, etapas de carga progresiva.

Conforme las plataformas alcanzan estabilidad suficiente, puede iniciarse la instalación de la infraestructura subterránea. En una urbanización portuaria, este componente es particularmente amplio e incluye redes de agua potable, agua cruda o industrial, drenaje sanitario, drenaje pluvial, líneas contra incendio, ductos eléctricos, canalizaciones para telecomunicaciones, fibra óptica, alumbrado exterior, sistemas de control, líneas de combustible si aplican, y obras asociadas como registros, cárcamos, pozos de visita, trincheras técnicas y estructuras de conexión. La secuencia constructiva de estas redes debe responder a una lógica de interferencias y jerarquías, ejecutando primero los sistemas de mayor profundidad y menor flexibilidad geométrica, para continuar con los de media y baja profundidad. En zonas con nivel freático alto, las excavaciones para redes enterradas requerirán procedimientos de control de agua, sostenimiento temporal y rellenos con materiales adecuados para evitar pérdida de confinamiento o flotación de tuberías.

El drenaje pluvial merece una consideración especial dentro del proceso constructivo de la urbanización, ya que en un entorno lagunar-portuario la capacidad de desalojo superficial y subterráneo del agua condiciona directamente la operatividad de todo el conjunto. La justificación técnica de su construcción prioritaria se basa en que las plataformas, pavimentos y edificaciones generan nuevas superficies impermeables y modifican los patrones naturales de escurrimiento. Por ello, antes de la pavimentación definitiva debe quedar resuelto un sistema integral compuesto por pendientes superficiales, rejillas, cunetas, colectores, obras de descarga, lagunas de regulación o estaciones de bombeo, según la topografía y la cota hidráulica del sitio. En proyectos portuarios, además, este drenaje puede requerir dispositivos de retención de sedimentos o trampas de

hidrocarburos en zonas operativas, lo que influye en la secuencia constructiva y en la integración de las obras electromecánicas.

Una vez que la infraestructura enterrada principal se encuentra instalada y protegida, puede avanzarse en la conformación de la estructura de pavimentos y superficies operativas. En la urbanización del puerto no todas las áreas tienen la misma exigencia estructural, por lo que el proceso constructivo debe diferenciar entre vialidades internas, patios logísticos, zonas de circulación de equipo pesado, áreas de transferencia, estacionamientos, andenes de carga y banquetas o circulaciones peatonales. En términos técnicos, esto implica distintas secciones estructurales, diferentes módulos de reacción esperados del terreno y, por tanto, soluciones de pavimento variables que pueden incluir bases granulares, subbases mejoradas, losas de concreto hidráulico, pavimentos asfálticos reforzados o combinaciones de estos sistemas. En áreas sujetas a cargas repetitivas elevadas, como patios de contenedores o zonas de operación de grúas y tractocamiones, la justificación técnica suele inclinarse hacia pavimentos rígidos o semirrígidos, debido a su mejor comportamiento frente a deformaciones permanentes y cargas concentradas.

Paralelamente a la construcción de plataformas y redes, debe iniciarse el proceso constructivo de las edificaciones. En el contexto de la ampliación del Puerto de Manzanillo, estas edificaciones pueden incluir edificios administrativos, casetas de acceso y control, cuartos de monitoreo, talleres de mantenimiento, almacenes, subestaciones eléctricas, edificios de servicios, puestos de inspección, áreas de seguridad, instalaciones aduanales u operativas y otras construcciones complementarias requeridas para la operación portuaria. La metodología de ejecución de estas edificaciones depende de su función, dimensiones y exigencias operativas, pero en todos los casos la primera decisión técnica relevante se relaciona con la cimentación.

En un terreno lagunar como el de Cuyutlán, las edificaciones ligeras de una planta podrían resolverse, en ciertos sectores previamente mejorados, mediante cimentaciones superficiales reforzadas o losas de cimentación, siempre que los estudios posteriores confirmen deformaciones admisibles. Sin embargo, para edificaciones críticas, estructuras con equipos sensibles, naves con claros considerables o construcciones sujetas a cargas elevadas, la solución más razonable es el empleo de cimentaciones profundas mediante pilotes o pilas, conectadas por trabes de liga, dados o losas estructurales. La justificación técnica de este enfoque radica en la necesidad de transmitir las cargas hacia estratos competentes y reducir la vulnerabilidad ante asentamientos diferenciales, que son uno de los principales riesgos en suelos de origen lacustre.

El procedimiento constructivo de las edificaciones debe seguir una secuencia ordenada que inicie con trazo y nivelación, continúe con excavaciones o perforaciones para cimentación, habilitado y colocación de acero, cimbrado y colado de elementos estructurales, y avance posteriormente hacia la superestructura. Cuando se trate de edificios de operación o administrativos, es factible prever sistemas estructurales de concreto reforzado, acero estructural o sistemas mixtos, seleccionados de manera preliminar con base en rapidez constructiva, durabilidad en ambiente marino y facilidad de mantenimiento. En edificios industriales o naves de

mantenimiento, los marcos de acero suelen ser técnicamente atractivos por su rapidez de montaje y por la posibilidad de salvar claros amplios con menor peso propio, aunque en ambientes costeros deben contemplarse sistemas de protección anticorrosiva robustos. En edificios menores, casetas y construcciones auxiliares, el concreto reforzado o la mampostería confinada pueden resultar viables siempre que se garantice su compatibilidad con las condiciones del sitio.

Una vez concluida la estructura principal de las edificaciones, el proceso constructivo continúa con la instalación de cubiertas, fachadas, cerramientos, pisos, cancelerías, impermeabilizaciones y sistemas interiores. Sin embargo, en un proyecto portuario el papel de las instalaciones electromecánicas adquiere una relevancia aún mayor que en una edificación convencional. Los edificios no deben considerarse únicamente como envolventes arquitectónicas, sino como nodos funcionales integrados a la operación general del puerto. En consecuencia, durante su ejecución debe coordinarse la instalación de tableros eléctricos, sistemas de respaldo, detección y supresión contra incendio, climatización, voz y datos, CCTV, control de accesos, tierras físicas, pararrayos, iluminación interior y exterior, y, cuando aplique, sistemas especiales vinculados con monitoreo logístico, seguridad o inspección. La secuencia constructiva debe prever esta integración desde etapas tempranas para evitar retrabajos o incompatibilidades entre obra civil y especialidades.

La urbanización con edificaciones también exige un tratamiento específico del espacio exterior inmediato a cada construcción. No basta con terminar el edificio; es necesario vincularlo funcionalmente con la red vial, las plataformas, los estacionamientos, los andenes, las redes de servicio y los sistemas de evacuación pluvial. Esto implica construir guarniciones, banquetas, rampas, accesos vehiculares, registros, áreas de carga y descarga, así como franjas técnicas para mantenimiento y operación. En edificios destinados a servicios críticos, la urbanización perimetral puede incluir además cercados, bollas, protecciones, casetas anexas o áreas de seguridad controlada.

En términos de organización de obra, la urbanización y las edificaciones deben ejecutarse mediante frentes coordinados, evitando que la instalación temprana de acabados o redes finales se vea afectada por la circulación posterior de maquinaria pesada. Por esta razón, la justificación técnica del proceso constructivo considera generalmente una secuencia escalonada, donde primero se resuelve la estabilización del terreno y la infraestructura primaria, después se desarrollan las plataformas y cimentaciones de edificios, posteriormente se ejecutan superestructuras y pavimentos pesados, y finalmente se concluyen instalaciones secundarias, acabados, señalización, alumbrado, paisajismo funcional si lo hubiere, pruebas y puesta en servicio. Esta lógica permite reducir interferencias, proteger los elementos terminados y mantener una trazabilidad más clara del control de calidad.

Otro aspecto esencial en la justificación del proceso constructivo es la durabilidad. Las obras de urbanización y las edificaciones en la Laguna de Cuyutlán estarán expuestas a un ambiente salino, humedad elevada, posible presencia de sulfatos y condiciones atmosféricas

corrosivas. Por ello, el procedimiento constructivo debe prever desde su concepción el empleo de materiales y sistemas compatibles con ese entorno. En concreto, esto puede implicar concretos con diseño específico para exposición agresiva, recubrimientos suficientes al acero de refuerzo, adiciones minerales, acero galvanizado o protegido, tuberías resistentes a corrosión, herrajes adecuados, sellos durables y estrategias de mantenimiento incorporadas al diseño preliminar. La justificación técnica no se limita entonces al “cómo construir”, sino también al “cómo asegurar que lo construido mantenga su desempeño durante la vida útil esperada”.

Finalmente, debe señalarse que, al encontrarse el proyecto en etapa conceptual y sin proyecto ejecutivo, el proceso constructivo para urbanización y edificaciones no pretende fijar una solución única e invariable, sino establecer un marco técnico coherente de ejecución. Ese marco parte del reconocimiento de las condiciones del sitio, de la experiencia acumulada en obras portuarias y lagunares, y de la necesidad de integrar infraestructura horizontal con edificaciones funcionales dentro de un mismo sistema operativo. En este contexto, la urbanización no debe verse como una etapa complementaria o secundaria, sino como la estructura territorial y funcional que hace posible la operación del puerto ampliado. Por tanto, su proceso constructivo debe ser concebido desde el inicio con el mismo nivel de rigor técnico que las vialidades principales o los viaductos, considerando que de su correcta ejecución dependerán tanto la operación cotidiana como la capacidad de crecimiento y adaptación futura del conjunto portuario.

4.0 EQUIPO DE CONSTRUCCIÓN.

4.1 Introducción

El desarrollo de infraestructura portuaria en la Laguna de Cuyutlán, asociado a la ampliación del Puerto de Manzanillo, implica la ejecución simultánea de obras de alta complejidad técnica, incluyendo vialidades a nivel, viaductos elevados carreteros, viaductos ferroviarios, urbanización y edificaciones. En este contexto, la selección, integración y operación de equipos de construcción no debe analizarse de manera aislada, sino como un sistema productivo interdependiente cuya eficiencia define directamente el éxito del proyecto.

El presente capítulo tiene como objetivo describir y justificar la configuración integrada de equipos, sus capacidades técnicas y su función dentro del proceso constructivo general. Este análisis se plantea en un nivel conceptual avanzado, orientado a la planeación de obra, evaluación de viabilidad y estructuración de estrategias constructivas.

4.2 Enfoque del Sistema Productivo.

El proyecto debe entenderse como un sistema de producción continua, en el cual cada tipo de equipo cumple una función específica dentro de una cadena constructiva que transforma el sitio desde su condición natural hasta su estado final operativo. La interacción entre equipos no es lineal, sino que responde a una lógica de frentes simultáneos donde múltiples procesos ocurren de manera paralela, pero sincronizada.

Dentro de este sistema, los equipos pueden agruparse funcionalmente en cinco grandes categorías: equipos de cimentación profunda, equipos de movimiento de tierras y mejoramiento de suelos, equipos de estructuras y montaje, equipos de producción de materiales y equipos especializados para infraestructura ferroviaria y urbana. La correcta integración de estas categorías permite mantener un flujo constante de producción, evitando interrupciones que afecten la ruta crítica del proyecto.

4.2.1 Sistema de Cimentaciones Profundas

El núcleo estructural del proyecto se encuentra en la ejecución de cimentaciones profundas, particularmente en los viaductos carreteros y ferroviarios. Para ello, se emplean perforadoras rotatorias de gran capacidad, capaces de ejecutar pilas de diámetros entre uno y dos metros y profundidades superiores a los treinta metros, en condiciones de suelo saturado.

El rendimiento de estos equipos, del orden de una a dos pilas por día por unidad, define la velocidad a la cual pueden liberarse frentes de subestructura. Su operación depende de sistemas auxiliares, como plantas de lodos bentoníticos, que permiten estabilizar las perforaciones y garantizar la calidad del proceso constructivo. La integración de estos equipos con grúas auxiliares

y sistemas de colado mediante tremie asegura la continuidad del proceso y la correcta ejecución de elementos estructurales críticos.

Desde un punto de vista técnico, este sistema representa el principal condicionante del programa de obra, ya que cualquier retraso en cimentaciones se traduce en una afectación directa a las etapas subsecuentes.

4.2.2 Sistema de Movimiento de Tierras y Mejoramiento del Terreno

Las condiciones geotécnicas de la Laguna de Cuyutlán requieren la implementación de un sistema robusto de movimiento de tierras y mejoramiento de suelos. Este sistema está compuesto por excavadoras hidráulicas, equipos de largo alcance, camiones de volteo, compactadores y motoconformadoras, que operan de manera coordinada para conformar plataformas estables y funcionales.

Las excavadoras, con capacidades de cuchara entre 1.5 y 4.5 metros cúbicos, permiten ejecutar movimientos de material en rangos de hasta 300 m^3 por día por equipo, mientras que los compactadores y motoconformadoras aseguran la correcta densificación y perfilado de las capas estructurales.

En paralelo, los equipos de mejoramiento de suelos, como sistemas de vibroflotación o instalación de drenes verticales, permiten modificar las propiedades del terreno, reduciendo asentamientos y mejorando la capacidad portante. Estos equipos operan con rendimientos del orden de cientos de metros cuadrados por día, y su correcta implementación es fundamental para garantizar la estabilidad de vialidades y plataformas.

4.2.3 Sistema de Dragado y Operación Lagunar

Dado que una parte significativa del proyecto se desarrolla en ambiente lagunar, el sistema de dragado y logística marítima adquiere una relevancia central. Este sistema se compone de dragas de succión o tipo backhoe, chalanes de gran capacidad y remolcadores, que en conjunto permiten la remoción y transporte de material en condiciones acuáticas.

Se tendrán dos equipos de dragado, el primero de ellos esta enfocado a la profundización de las áreas de navegación, siendo este el equipo mayor, y el segundo como apoyo a la construcción de los viaductos elevados de las vialidades y ferroviarias.

El primero de ellos se compone de dragas de succión con cortador autopropulsada de corte de alta resistencia para dragado, con un diámetro de la boca de succión de 1.00 m y con una potencia total instalada de 23,000 kW. Dichos equipos contarán con el apoyo de barcazas de 10,000 m^3 de capacidad y remolcadores para el traslado de estos. En la zona de rellenos se contara

con equipo terrestre para el movimiento de tierras como son cargadores frontales, tractores, motoconformadoras y camiones de volteo.

Para el segundo caso, las dragas pueden alcanzar producciones que varían entre 500 y 3,000 m³ por día, dependiendo del tipo de material y de la configuración del equipo. Los chalanes, con capacidades de hasta 2,000 m³, aseguran el transporte continuo del material dragado, mientras que los remolcadores proporcionan la movilidad necesaria dentro del sistema.

La integración de este sistema con las actividades terrestres es crítica, ya que permite generar condiciones adecuadas para la construcción de cimentaciones y estructuras en zonas inicialmente inaccesibles.

4.2.4 Sistema de Estructuras y Montaje

La construcción de la superestructura de viaductos requiere un sistema especializado de equipos de izaje y montaje, integrado por grúas de gran capacidad, grúas sobre chalanes y, en algunos casos, sistemas lanzadores de vigas.

Las grúas sobre orugas, con capacidades que pueden alcanzar las 500 toneladas, permiten el manejo de elementos prefabricados de gran peso, mientras que los sistemas lanzadores facilitan el montaje en zonas donde el acceso es limitado o donde se requiere una mayor continuidad en el proceso constructivo.

El rendimiento de estos equipos se mide en número de elementos montados por día, y su operación requiere una coordinación precisa con la logística de transporte y la disponibilidad de elementos prefabricados. En este sentido, la planta de prefabricados juega un papel fundamental, ya que asegura el suministro continuo de trabes y elementos estructurales.

4.2.5 Sistema de Producción y Colocación de Concreto

El concreto constituye uno de los materiales más utilizados en el proyecto, por lo que su producción y colocación deben gestionarse como un sistema independiente. Este sistema incluye plantas de concreto con capacidades superiores a 100 m³ por hora, camiones revolvedores para el transporte y bombas de concreto para su colocación.

La capacidad de este sistema debe dimensionarse para satisfacer la demanda simultánea de múltiples frentes de trabajo, evitando interrupciones que puedan afectar la calidad del material o la continuidad de los colados. En proyectos de esta magnitud, la planta de concreto se convierte en un punto crítico de control, cuya operación debe ser continua y confiable.

4.2.6 Sistema de Pavimentación y Acabados

La construcción de vialidades y superficies operativas requiere el uso de equipos especializados para la colocación de pavimentos, tanto rígidos como flexibles. Las extendedoras de concreto tipo slipform permiten ejecutar pavimentos de alta calidad con rendimientos de varios cientos de metros por día, mientras que las extendedoras asfálticas se utilizan en áreas de menor exigencia estructural.

El tren de pavimentación, integrado por múltiples equipos, permite mantener un flujo continuo de producción, asegurando la calidad y uniformidad de las capas. Este sistema debe coordinarse estrechamente con las etapas de terracería y urbanización para evitar interferencias.

4.2.7 Sistema Ferroviario

El sistema ferroviario requiere equipos especializados para la instalación y ajuste de la vía, incluyendo trenes de tendido, bateadoras y perfiladoras de balasto. Estos equipos permiten alcanzar rendimientos de hasta un kilómetro de vía por día, siempre que la infraestructura base se encuentre completamente terminada.

La precisión de estos equipos es fundamental, ya que la operación ferroviaria exige tolerancias geométricas muy estrictas. Por ello, su operación se complementa con sistemas avanzados de control topográfico.

4.2.8 Sistema de Control y Soporte

Finalmente, el sistema productivo se complementa con equipos de control y soporte, incluyendo sistemas topográficos de alta precisión, plantas eléctricas, laboratorios de control de calidad y equipos de mantenimiento. Estos elementos, aunque no participan directamente en la producción, son esenciales para garantizar la correcta ejecución del proyecto.

4.2.9 Resumen.

De acuerdo con lo anterior, en la Tabla 4.1 se presenta el resumen del equipo que en un momento dado podría ser usado en la construcción de las vialidades, viaducto ferroviario y la urbanización de la ampliación del puerto de Manzanillo en la Lagua de Cuyutlán.

El análisis integrado de equipos, capacidades y funciones demuestra que la ejecución del proyecto en la Laguna de Cuyutlán depende de la operación coordinada de múltiples sistemas productivos interdependientes. Cada equipo cumple una función específica dentro de una cadena constructiva compleja, donde la continuidad y sincronización de procesos resultan más importantes que la capacidad individual de cada unidad.

Tabla 4.1 Relación del Equipo para la Obra.

EQUIPO	TIPO / CONFIGURACIÓN	CAPACIDAD TÉCNICA	RENDIMIENTO TÍPICO	FUNCIÓN DENTRO DEL PROCESO CONSTRUCTIVO	OBSERVACIONES TÉCNICAS
Perforadora rotatoria para pilas	Bauer BG / Soilmec SR	Diámetro: 1.0 – 2.5 m | Profundidad: 25 – 45 m	1.0 – 2.0 pilas/día/equipo	Cimentación profunda (viaductos carreteros y ferroviarios)	Requiere lodos bentoníticos o ent crítica en control de verticalidad
Planta de lodos bentoníticos	Sistema modular	50 – 150 m³/h	Soporte continuo	Estabilización de perforaciones	Fundamental en suelos saturados Cuyutlán
Grúa sobre orugas	150 – 500 ton	Radio: 40 – 80 m	6 – 12 izajes/día	Montaje de trabes, acero, prefabricados	En Cuyutlán se documentan has ton
Grúa sobre chalan	80 – 300 ton	Izaje marino	Variable	Montaje en zona lagunar	Requiere control de estabilidad y
Sistema lanzador de vigas	Viga lanzadora	Claros: 25 – 45 m	1 – 2 trabes/día	Montaje de superestructura	Reduce dependencia de grúas er confinadas
Excavadora hidráulica	30 – 80 ton	Cuchara: 1.5 – 4.5 m³	150 – 300 m³/día	Terracerías, urbanización, plataformas	Equipo base de obra
Excavadora largo alcance	40 – 70 ton	Alcance: 15 – 25 m	80 – 150 m³/día	Trabajo en zonas inundadas	Clave en laguna
Compactador vibratorio	10 – 20 ton	200 – 400 kN	2,000 – 4,000 m²/día	Compactación de terraplenes	Control crítico en vialidades
Motoconformadora	140 – 220 HP	Hoja: 3.7 m	1 – 2 km/día	Perfilado de capas	Control geométrico
Draga de succión con cortador (CSD)	40”	Potencia: 23,000 kW	50,000 m³/día	Dragado lagunar – áreas de navegación	Depende de material
Cargador frontal	Cargador de ruedas 950 GC	Potencia: 151 kW	1,328 m³/día	Movimiento de tierras	Equipo base de obra
Tractor	Tractor D9	Potencia: 337 kW	400 – 800 m³/día	Movimiento de tierras	Equipo base de obra
Draga de succión (CSD)	12” – 24”	Potencia: 500 – 3,000 kW	500 – 3,000 m³/día	Dragado lagunar – apoyo a construcción de viaductos	Depende de material
Draga tipo backhoe	25 – 60 ton	Cuchara: 1 – 4 m³	300 – 800 m³/día	Dragado de precisión	Mejor control que CSD
Chalán (barcaza)	500 – 2,000 m³	1,000 – 3,000 ton	Ciclos logísticos	Transporte de material	Depende distancia
Remolcador	800 – 2,000 HP	Bollard pull: 10 – 25 ton	Apoyo continuo	Maniobras marítimas	Esencial en logística
Planta de concreto	Fija/móvil	60 – 150 m³/h	500 – 1,000 m³/día	Producción de concreto	Cuello de botella potencial
Bomba de concreto	Pluma 36 – 52 m	100 – 160 m³/h	300 – 600 m³/día	Colado en pilas/estructuras	Fundamental en viaductos
Camión revolvedor	7 – 10 m³	20 – 40 viajes/día	150 – 300 m³/día	Transporte de concreto	Depende logística
Camión de volteo	14 – 20 m³	20 – 30 ton	200 – 400 m³/día	Terracerías	Alta dependencia de acarreo
Equipo de mejoramiento de suelo	Vibroflot / drenes	Profundidad: 10 – 25 m	200 – 500 m²/día	Estabilización del terreno	Crítico en Cuyutlán
Extendedora de concreto	Slipform	4 – 8 m ancho	200 – 500 m/día	Pavimentos rígidos	Ideal en patios portuarios
Extendedora asfáltica	Finisher	6 – 10 m ancho	300 – 800 ton/día	Pavimentos flexibles	Para vialidades secundarias
Tren de pavimentación	Completo	Variable	Alta productividad	Pavimentos pesados	Integración de equipos
Equipo ferroviario	Tendido y bateo	500 – 1,000 m/día	Ajuste fino	Instalación de vía	Alta precisión
Bateadora ferroviaria	Automática	±1 mm tolerancia	500 – 800 m/día	Nivelación de vía	Crítica en operación
Perfiladora de balasto	Especializada	300 – 600 m/día	Distribución	Ajuste geométrico	Complementaria
Planta de prefabricados	Industrial	2 – 10 trabes/día	Variable	Producción de vigas	Reduce tiempos
Sistema tremie	Ø 200 – 300 mm	Colado continuo	Según pila	Concreto bajo agua	Evita segregación
Equipo topográfico	GPS RTK / estación total	Precisión mm–cm	Control continuo	Control geométrico	Crítico en ferroviario
Planta eléctrica / subestación temporal	100 – 500 kVA	Suministro continuo	—	Energía en obra	Soporte integral

Tabla 4.2 Relación del Equipo Menor para la Obra.

SISTEMA / ACTIVIDAD	PROCEDIMIENTO ASOCIADO	EQUIPO MENOR DE OBRA	USO ESPECÍFICO
Dragado y rellenos	Control de tuberías, vertido y manejo de flujo	Válvulas, bridas, conexiones, mangueras de alta presión	Control del transporte hidráulico del material
	Control de sedimentación	Barreras de geotextil, estacas, anclajes	Contención de finos en zonas de vertido
	Supervisión de descarga	Boyas, balizas, cintas de señalización	Delimitación de áreas operativas
Topografía y control	Control topobatimétrico	Prismas, estadales, jalones, bases de replanteo	Control geométrico de obra
	Monitoreo de asentamientos	Testigos, placas de asentamiento, piezómetros simples	Seguimiento del comportamiento del relleno
Mejoramiento del terreno (vibroflotación)	Preparación y ejecución	Mangueras, conexiones de agua/aire, válvulas	Alimentación del vibrador
	Control de proceso	Instrumentación básica (reglas, niveles manuales)	Verificación de profundidades y avances
Instalaciones provisionales	Oficinas y campamento	Generadores portátiles, luminarias, cableado, tableros	Suministro eléctrico temporal
	Servicios generales	Tanques de agua, bombas, sanitarios portátiles	Operación del campamento
	Talleres	Herramienta manual (llaves, esmeriles, taladros)	Mantenimiento menor
Fabricación y habilitado de acero	Corte y armado	Cortadoras, dobladoras, equipos de oxicorte	Habilitado de acero
	Soldadura	Plantas de soldar, electrodos, cables, pinzas	Uniones metálicas
	Control de calidad	Equipos de medición, galgas, escuadras	Verificación de armado
Sand blast y recubrimientos	Limpieza mecánica	Mangueras, boquillas, equipos de protección personal	Aplicación de chorro abrasivo
	Pintura anticorrosiva	Pistolas de pintura, compresores, recipientes	Aplicación de primarios y recubrimientos
Hincado de tablestacas	Control de verticalidad	Niveles, plomadas, reglas metálicas	Alineación de elementos
	Operación de hinca	Capuchones, amortiguadores, guías	Protección de cabezas y control de impacto
	Registro de hincado	Formatos, contadores manuales, marcadores	Control de golpes y penetración
Pilas con perforación previa (Cimentación)	Trazo y posicionamiento	Estacas, pintura, cintas, nivel manual	Ubicación de pilas
	Control de verticalidad	Plomadas, niveles, reglas metálicas	Verificación de alineación
	Perforación	Brocas auxiliares, dientes de corte, herramientas de limpieza (cucharas, botes)	Apoyo a perforación
	Manejo de ademe	Llaves, pernos, cuñas, eslingas, grilletes	Montaje/desmontaje de ademe
	Limpieza de fondo	Cubetas, bombas sumergibles, mangueras	Retiro de detritos y agua
	Colocación de acero	Separadores (donas), amarres, alambre recocido	Control de recubrimiento
	Izaje de armado	Eslingas, cables, grilletes, ganchos	Maniobras seguras
	Colado (tremie)	Tubos tremie, embudos, sellos, cubetas	Colocación de concreto bajo agua
	Control de concreto	Cono de revenimiento, moldes, termómetro	Control de calidad
	Descabezado de pilas	Martillos neumáticos, compresores, cinceles	Retiro de concreto contaminado
Construcción de muelle	Colado de concreto	Vibradores, reglas, cucharones, cubetas	Colocación y acabado
	Cimbra	Puntales, cuñas, tornillería, andamios	Soporte temporal
	Control de concreto	Conos de revenimiento, moldes, termómetros	Ensayes de calidad
Terracerías y accesos	Extendido y compactación	Estacas, cuerdas, reglas, medidores de humedad	Control de niveles y compactación
	Riego	Mangueras, aspersores	Control de humedad
Logística y seguridad	Señalización	Conos, cintas, lámparas, radios de comunicación	Seguridad en obra
	Maniobras	Eslingas, grilletes, cables, ganchos	Izaje y sujeción
	Seguridad industrial	EPP (cascos, chalecos, arneses, respiradores)	Protección del personal

Fuente: Elaboración propia, 2026.

En este contexto, la correcta planificación y gestión de los equipos no solo garantiza la viabilidad técnica del proyecto, sino que constituye el principal factor de control sobre los tiempos, costos y calidad de la obra. El enfoque adoptado, basado en la integración de sistemas, permite enfrentar las condiciones adversas del entorno y establecer una base sólida para el desarrollo exitoso del proyecto en etapas posteriores.

4.3 Organización y Dimensionamiento del Personal de Obra

4.3.1 Introducción

El desarrollo de obras de infraestructura de gran escala, como la ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán, requiere no solo de una adecuada selección de equipos y métodos constructivos, sino también de una correcta planeación y organización del recurso humano. En este tipo de proyectos, la fuerza laboral constituye un componente crítico del sistema productivo, cuya estructura, especialización y distribución influyen directamente en la productividad, la calidad de la obra y el cumplimiento del programa.

En nuestro caso en particular, este aspecto adquiere una relevancia debido a la complejidad del entorno lagunar, la coexistencia de múltiples frentes de trabajo y la alta interdependencia entre procesos constructivos.

El presente apartado tiene como objetivo desarrollar y justificar la estructura del personal previamente estimada para tres escenarios operativos[4]: optimizado, base (realista) y alto (conservador), describiendo su distribución por áreas, su función dentro del proceso constructivo y su relación con los sistemas productivos definidos. Este análisis se realiza en un nivel conceptual avanzado, orientado a la planeación de obra y evaluación de viabilidad.

4.3.2 Enfoque General de Organización del Personal

La organización del personal en el proyecto se basa en un modelo de frentes simultáneos, en el cual cada sistema constructivo cuenta con equipos humanos especializados que operan de manera paralela, pero coordinada. Este enfoque permite sostener altos niveles de producción, reducir tiempos de ejecución y mantener control sobre la calidad de los trabajos.

A diferencia de proyectos lineales, donde la mano de obra se desplaza secuencialmente entre actividades, en este caso se requiere una estructura estable y permanente en cada frente, con capacidades suficientes para operar de manera continua. Esto implica la coexistencia de múltiples cuadrillas especializadas, cada una con funciones claramente definidas dentro del sistema productivo.

La estimación global del personal se presenta en la Tabla 4.3, la cantidad de personal presentado es aproximado pero consistente con la magnitud de los volúmenes de obra, la cantidad de frentes activos y la necesidad de mantener operaciones simultáneas en condiciones complejas.

[4] Cada escenario responde a distintas condiciones de ejecución, niveles de incertidumbre y eficiencia operativa, permitiendo establecer rangos de personal técnicamente justificables para la planeación del proyecto.

Tabla 4.3 Estimación de la Cantidad de Personal en Obra.

ÁREA	ESCENARIO		
	OPTIMIZADO	BASE	CONSERVADOR
Dragado	110	130	141 – 173
Tablestacado	244	290	314 – 386
Cimentaciones	101	120	130 – 160
Subestructura	76	90	100 – 120
Superestructura	68	80	90 – 110
Terracerías	68	80	90 – 110
Urbanización	59	70	80 – 100
Edificaciones	51	60	70 – 90
Ferroviario	42	50	50 – 70
Logística y mantenimiento	51	60	80 – 90
Supervisión, QA/QC, seguridad	34	40	50 – 60
TOTAL	**904**	**1,070**	**1,195 – 1,469**

Nota: La cantidad de personal presentado en la tabla es por un solo turno.
Fuente: Elaboración propia, 2026.

4.3.3 Metodología de Estimación

El escalamiento del personal se basa en un enfoque de ingeniería de producción, en el cual la cantidad de trabajadores no se determina únicamente por volúmenes de obra, sino por la estructura de frentes simultáneos, la configuración de equipos y la eficiencia operativa del sistema constructivo.

Se parte de un escenario optimizado previamente definido, el cual representa condiciones ideales de ejecución, y se introducen factores de ajuste asociados a condiciones reales de obra, tales como interferencias entre frentes, variabilidad geotécnica, logística en ambiente lagunar y riesgos operativos. Estos factores impactan principalmente en la necesidad de personal indirecto, de soporte y de supervisión, más que en el incremento proporcional de mano de obra directa.

4.3.3.1 Escenario optimizado

El escenario optimizado representa una condición ideal de ejecución, en la cual los frentes de trabajo operan de manera continua, con mínima interferencia entre actividades, logística eficiente y disponibilidad constante de recursos.

En este contexto, el personal estimado se sitúa en un rango de 904 a 1,070 personas, distribuido entre los distintos sistemas constructivos. Esta cifra es consistente con una configuración de obra en la que los equipos operan a su capacidad nominal y los rendimientos alcanzan los valores esperados.

Desde el punto de vista técnico, este escenario implica que las cimentaciones profundas avanzan sin interrupciones, liberando frentes de subestructura de manera constante, mientras que el montaje de la superestructura se realiza con una logística fluida. Las actividades de terracería, urbanización y edificaciones se desarrollan en paralelo, sin generar conflictos significativos.

Este escenario constituye una referencia teórica que permite establecer la base mínima de personal necesaria para ejecutar el proyecto bajo condiciones ideales.

4.3.3.2 Escenario base (realista)

El escenario base incorpora las condiciones típicas de ejecución en un proyecto de esta naturaleza, donde es esperable la presencia de interferencias operativas, variaciones en la productividad de los equipos y ajustes derivados de condiciones geotécnicas o logísticas.

En este caso, el personal estimado se incrementa a un rango de 1,070 a 1,195 personas. Este aumento no responde a un incremento proporcional en la producción, sino a la necesidad de incorporar personal adicional en áreas de soporte, mantenimiento, logística y supervisión.

Desde el punto de vista técnico, este escenario refleja una operación en la que los frentes de trabajo no siempre operan a su máxima eficiencia, lo que obliga a implementar estrategias de recuperación de producción, como el aumento de cuadrillas o la extensión de horarios. Asimismo, la complejidad del entorno lagunar puede generar retrasos en el suministro de materiales o en la movilización de equipos, lo que requiere una mayor capacidad de respuesta operativa.

El incremento de personal en este escenario se concentra principalmente en actividades indirectas, tales como mantenimiento de equipos, control de calidad, logística interna y coordinación de frentes, lo que permite sostener la continuidad del proceso constructivo a pesar de las variaciones en la operación.

4.3.3.3 Escenario alto (conservador)

El escenario alto considera condiciones adversas de ejecución, en las cuales los factores de incertidumbre tienen un impacto significativo en la productividad del proyecto. Entre estos factores se incluyen condiciones geotécnicas más desfavorables de lo previsto, dificultades de acceso en zonas lagunares, condiciones climáticas adversas y la necesidad de retrabajos o ajustes constructivos.

En este contexto, el personal requerido se incrementa a un rango de 1,195 a 1,469 personas. Este aumento responde principalmente a la necesidad de reforzar los sistemas de soporte, supervisión y control, más que a un incremento directo en la producción.

Desde una perspectiva técnica, este escenario se caracteriza por una menor eficiencia global del sistema productivo, donde los tiempos muertos, las interferencias entre frentes y los ajustes operativos reducen la productividad efectiva de los equipos. Para compensar estos efectos, se incrementa la cantidad de personal en áreas clave, como logística, mantenimiento y control de calidad, lo que permite mantener la operación del proyecto dentro de parámetros aceptables.

Es importante destacar que, en este escenario, el incremento de personal no necesariamente se traduce en una reducción de los tiempos de ejecución, ya que la productividad del sistema está limitada por factores externos. En este sentido, el personal adicional actúa como un mecanismo de mitigación de riesgos, más que como un acelerador de la producción.

4.3.4 Análisis comparativo de escenarios

El análisis de los tres escenarios permite identificar que el incremento de personal no es lineal respecto a la complejidad del proyecto. Mientras que el paso del escenario optimizado al base implica un incremento moderado asociado a condiciones reales de operación, el paso al escenario alto refleja un cambio en la estructura del personal, con mayor peso en funciones de soporte y control.

Este comportamiento es consistente con la naturaleza del proyecto, donde la eficiencia no depende únicamente de la cantidad de mano de obra, sino de la coordinación entre frentes, la logística y la gestión de recursos. En consecuencia, el aumento de personal en escenarios adversos responde a la necesidad de compensar ineficiencias del sistema, más que a un aumento en la capacidad productiva.

4.3.5 Implicaciones para la planeación del proyecto

El escalamiento del personal por escenario tiene implicaciones directas en la planeación del proyecto, particularmente en la estimación de costos, la logística de campamentos, la gestión de recursos humanos y la organización de la obra.

En términos de costos, el incremento de personal en escenarios base y alto implica un aumento en los gastos indirectos, lo que debe considerarse en la estimación del CAPEX y en la definición de contingencias. Desde el punto de vista logístico, la presencia de un mayor número de trabajadores requiere instalaciones adecuadas para alojamiento, alimentación, transporte interno y servicios.

Asimismo, la organización del personal debe adaptarse a cada escenario, estableciendo estructuras jerárquicas claras y mecanismos de coordinación eficientes que permitan gestionar la complejidad del proyecto.

Por último, el análisis del escalamiento de personal por escenario demuestra que el dimensionamiento del recurso humano en el proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán debe abordarse como un proceso dinámico, adaptado a las condiciones reales de ejecución.

El rango de 904 a 1,070 personas en escenario optimizado representa la base mínima de operación, mientras que los rangos de 1,070 a 1,195 personas en escenario base y de 1,195 a 1,469 personas en escenario alto reflejan la necesidad de incorporar capacidades adicionales para enfrentar la variabilidad del entorno.

En este sentido, la correcta planificación del personal no solo permite garantizar la viabilidad del proyecto, sino que constituye una herramienta fundamental para la gestión de riesgos, la optimización de recursos y el cumplimiento de los objetivos de tiempo, costo y calidad.

5.0 PROGRAMA DE OBRA.

El programa de obra desarrollado para el proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán constituye un instrumento fundamental de planeación que integra, en una secuencia lógica y temporal, los estudios, proyectos ejecutivos y actividades constructivas necesarias para materializar la infraestructura portuaria. Este programa abarca un horizonte plurianual comprendido entre los años 2026 y 2031, reflejando la magnitud del proyecto y la necesidad de estructurar su ejecución en etapas claramente definidas.

El presente informe técnico tiene como objetivo explicar y justificar la lógica del programa de obra, vinculándolo con el escenario de configuración de obra previamente desarrollado, la estructura de frentes simultáneos, el dimensionamiento de personal y la integración de sistemas constructivos. La interpretación del programa permite entender no solo la secuencia de actividades, sino también la estrategia técnica que sustenta su viabilidad.

5.1 Estructura General del Programa

El programa se organiza en tres grandes bloques claramente diferenciados: estudios, proyectos ejecutivos y construcción. Esta estructura responde a una lógica de maduración progresiva del proyecto, donde primero se consolidan las bases técnicas, posteriormente se desarrolla la ingeniería de detalle y finalmente se ejecutan las obras.

En la primera fase, correspondiente a estudios, se incluyen análisis fundamentales como la disponibilidad de agua, demanda energética, factibilidad de suministros, estudios de riesgo, análisis hidráulicos y estudios para el manejo de material de dragado. Esta etapa se concentra principalmente en el arranque del programa, durante el año 2026, lo cual es técnicamente consistente, ya que estos estudios constituyen la base para el desarrollo de los proyectos ejecutivos.

La segunda fase, correspondiente a proyectos, se desarrolla de manera traslapada con los estudios y se extiende hacia los años posteriores. En esta etapa se elaboran los proyectos ejecutivos de todos los sistemas que integran el puerto, incluyendo vialidades, viaductos, redes eléctricas, sistemas hidráulicos, edificaciones, infraestructura ferroviaria y obras marítimas. La simultaneidad parcial entre estudios y proyectos refleja una estrategia de avance acelerado, donde la información preliminar permite iniciar el diseño sin esperar la conclusión total de todos los estudios.

La tercera fase, correspondiente a la construcción y supervisión, constituye el bloque de mayor duración y complejidad, extendiéndose a lo largo de varios años y estructurándose en múltiples frentes de trabajo.

5.1.1 Lógica de la fase de estudios

La fase de estudios se caracteriza por su alta densidad técnica y por su impacto directo en las decisiones posteriores del proyecto. La inclusión de estudios de disponibilidad de agua, demanda hídrica, demanda eléctrica y factibilidad de suministro energético responde a la necesidad de garantizar la autosuficiencia operativa del puerto desde su concepción.

Asimismo, la incorporación del análisis cuantitativo de riesgos (QRA) es particularmente relevante en un proyecto portuario de esta naturaleza, ya que permite definir la compatibilidad entre diferentes instalaciones y establecer criterios de zonificación que eviten conflictos entre áreas operativas, administrativas y de riesgo. Este aspecto es fundamental en un modelo portuario integrado, donde coexisten múltiples funciones en un mismo espacio.

Los estudios relacionados con el manejo hidráulico, incluyendo el sistema fluvial del arroyo Zacate y el abastecimiento de agua, reflejan la importancia de controlar la interacción entre la infraestructura y el entorno natural, particularmente en un sistema lagunar donde el comportamiento del agua es un factor determinante.

5.1.2 Lógica de la fase de proyectos ejecutivos

La fase de proyectos ejecutivos se desarrolla de manera progresiva y traslapada, lo cual permite iniciar la construcción de ciertos componentes mientras otros aún se encuentran en fase de diseño. Esta estrategia es coherente con el escenario de configuración de obra previamente definido, donde la ejecución se basa en frentes simultáneos.

El programa incluye proyectos ejecutivos para todos los sistemas del puerto, lo que refleja un enfoque integral. Destaca la presencia de proyectos específicos para vialidades, conectividad ferroviaria, redes eléctricas, sistemas hidráulicos, edificaciones, muelles, torre de tráfico marítimo y centros operativos. Esta diversidad de proyectos confirma que el puerto se concibe como un sistema intermodal complejo, donde cada componente debe integrarse de manera funcional.

La inclusión de proyectos de compactación de rellenos y de estructuras de acceso indica que el diseño geotécnico y la estabilidad del terreno son elementos centrales en el desarrollo del proyecto, lo cual es consistente con las condiciones de la Laguna de Cuyutlán.

5.1.3 Lógica de la fase constructiva

La fase constructiva del programa se organiza en una secuencia que refleja la lógica técnica del proceso constructivo en un entorno lagunar. Esta secuencia inicia con la ejecución de obras auxiliares, que incluyen patios de almacenamiento, muelles auxiliares y caminos provisionales. Estas actividades son indispensables para habilitar el sitio y permitir la operación de equipos pesados.

Posteriormente, el programa contempla la ejecución de dragado, que incluye actividades como batimetría inicial, dragado de arcillas y arenas, corte de roca submarina y batimetría final. Este bloque constituye la base para la conformación de áreas operativas y canales de acceso, y su ejecución temprana es coherente con la necesidad de preparar el entorno físico del proyecto.

A continuación, se desarrollan los rellenos, que incluyen el vertido de material, la conformación de tarquinas y la construcción de plataformas. Estas actividades permiten generar superficies utilizables sobre las cuales se desarrollarán las demás infraestructuras.

El programa incorpora también la ejecución de tablestacado, que incluye la instalación de sistemas de contención en distintas zonas del proyecto. Esta actividad es clave para estabilizar los rellenos y definir los límites de las áreas operativas.

Una vez establecidas las condiciones físicas del sitio, el programa contempla la ejecución de los principales sistemas del puerto, incluyendo vialidades, ferrocarril, zona administrativa, estacionamientos, redes de servicios, torre de tráfico marítimo, muelle de remolcadores y centro de investigación. La ejecución de estos componentes se realiza de manera paralela, lo cual es consistente con el modelo de frentes simultáneos.

5.2 Relación con el Escenario de Configuración de Obra

El programa de obra refleja de manera clara el escenario de configuración previamente desarrollado. La simultaneidad de actividades en la fase constructiva confirma que el proyecto se ejecutará mediante múltiples frentes de trabajo, cada uno con su propia configuración de equipos y personal.

La secuencia de actividades muestra que el frente de cimentaciones profundas, aunque no aparece explícitamente como tal, está implícito dentro de los proyectos de viaductos y estructuras, y constituye la base para la ejecución de las etapas posteriores. De igual manera, los frentes de terracerías, urbanización y edificaciones se desarrollan en paralelo, aprovechando la liberación progresiva de áreas.

El sistema ferroviario se ubica en una etapa posterior, lo cual es consistente con la necesidad de contar con la infraestructura estructural previamente terminada.

5.3 Identificación de la Ruta Crítica

El análisis del programa permite identificar que la ruta crítica del proyecto está asociada a la ejecución de obras estructurales y a la preparación del terreno, particularmente el dragado, los rellenos y las estructuras de contención. Estas actividades condicionan el inicio de la mayoría de los frentes constructivos.

Asimismo, los proyectos ejecutivos de vialidades, viaductos y sistemas ferroviarios representan hitos clave, ya que su conclusión permite iniciar las etapas constructivas correspondientes.

5.4 Coherencia Técnica del Programa

El programa de obra presenta una coherencia técnica notable, ya que sigue una secuencia lógica que inicia con la generación de información, continúa con el desarrollo de diseño y culmina con la ejecución de obra. El traslape de actividades permite optimizar los tiempos de ejecución, sin comprometer la viabilidad técnica.

La inclusión de obras auxiliares, actividades de dragado, rellenos y estructuras de contención en etapas tempranas refleja un entendimiento adecuado de las condiciones del sitio y de la necesidad de preparar el terreno antes de desarrollar infraestructura permanente.

5.5 Comentarios Finales

El programa de obra analizado, ver Tabla 3.4, constituye una herramienta técnica sólida que integra de manera coherente las distintas etapas del proyecto de ampliación del Puerto de Manzanillo en la Laguna de Cuyutlán. Su estructura refleja un enfoque estratégico basado en la ejecución simultánea de frentes de trabajo, la optimización de tiempos y la adaptación a las condiciones del entorno lagunar.

La relación entre el programa, el escenario de configuración de obra y la organización de recursos confirma la viabilidad del proyecto desde el punto de vista constructivo, siempre que se mantenga una adecuada coordinación entre frentes, una gestión eficiente de recursos y un control riguroso de las variables críticas del proyecto.

En este sentido, el programa no solo define una secuencia temporal, sino que representa la materialización de la estrategia técnica que permitirá ejecutar una obra de alta complejidad en condiciones exigentes.

Nota:

(1) Interfaces entre instalaciones peligrosas y otras funciones del puerto. Especialmente donde una instalación de riesgo quede cerca de: edificio administrativo, torre de tráfico marítimo, vialidades principales, muelle de remolcadores, subestaciones, áreas de mantenimiento y zonas de personal

Aquí el QRA es clave para decidir qué sí puede colindar y qué no. En tu caso esto importa mucho porque el proyecto busca una lógica port-led, es decir, integrar infraestructura marítima, patios, accesos, intermodalidad y nodos externos como un solo sistema. Esa integración aumenta la necesidad de separar correctamente los usos incompatibles.

(2) Incluye: estudio de mecánica de suelos, topografía, obras de canalización, protección, regulación hidráulica y descarga al Vaso II

(3) Incluye: estudio de mecánica de suelos, topografía, planta potabilizadora, pozo para suministro de agua, diseño estructural, diseño electromecánico y redes de servicios para la planta.

(4) Incluye: estudio de mecánica de suelos, topografía, estudio de factibilidad de uso de plantas prefabricadas o el diseño de una planta de tratamiento general, evaluació de alternativa de plantas prefabricadas o en su defecto el diseño de una planta de tratamiento (para el caso de la planta de tratamiento, considerar el diseño estructural, diseño electromecánico y redes de servicios para la planta de tratamiento)

(5) Incluye: estudio de mecánica de suelos, topobatimetría, proyecto estructural de viaductos, proyecto geométrico, diseño de estructura de pavimento, obras de drenaje (alcantarillas, cunetas), señalamiento horizontal y vertical, Intersecciones y accesos logísticos.

(6) Incluye: estudio de mecánica de suelos, topobatimetría, proyecto estructural de viaductos (cimentación profunda y superestructura), proyecto geométrico, vía férrea (balasto, durmientes, riel), señalización ferroviaria y drenaje del viaducto, obras de drenaje (alcantarillas, cunetas), intersecciones y accesos logísticos.

(7) Incluye: estudio de mecánica de suelos, topografía, proyecto arquitectónico, diseño estructural de las edificaciones y redes de servicios (energía eléctrica, iluminación, agua potable, HVAC, instalaciones sanitarias, CCTV, red de telecomunicaciones e instalaciones especiales.

(8) Incluye: estudio de mecánica de suelos, topografía, proyecto arquitectónico, diseño estructural de las edificaciones y redes de servicios (energía eléctrica, iluminación, agua potable, HVAC, instalaciones sanitarias, CCTV, red de telecomunicaciones e instalaciones especiales.

(9) Incluye: estudio de mecánica de suelos, topografía, proyecto geométrico, diseño de estructura de pavimento, obras de drenaje (alcantarillas, cunetas), señalamiento horizontal y vertical, Intersecciones y accesos logísticos, proyecto de iluminación, proyecto de baños, instalaciones hidráulicas, instalaciones sanitarias, proyecto estructural de edificaciones (comedor y tiendas de conveniencia) y proyecto de casetas de acceso (incluye redes de servicios).

(10) Incluye: estudio de mecánica de suelos, topobatimetría, proyecto geométrico, diseño estructural del muelle y estructuras en tierra, obras de drenaje (alcantarillas, cunetas), proyecto de iluminación, proyecto de instalaciones hidráulicas, instalaciones sanitarias, proyecto de elementos de atraque y amarre y proyecto de señalización marítima.

(11) Incluye: estudio de mecánica de suelos y mecánica de rocas, topografía, proyecto arquitectónico, diseño estructural de las edificaciones y redes de servicios (energía eléctrica, iluminación, agua potable, HVAC, instalaciones sanitarias, CCTV, red de telecomunicaciones, instalaciones especiales, diseño de vialidades (proyecto geométrico, diseño de estructura de pavimento, obras de drenaje (alcantarillas, cunetas), señalamiento horizontal y vertical, proyecto de iluminación y proyecto de la caseta de acceso).

(12) Incluye: estudio de mecánica de suelos, topografía, proyecto arquitectónico, diseño estructural de las edificaciones y redes de servicios (energía eléctrica, iluminación, agua potable, HVAC, instalaciones sanitarias, CCTV, red de telecomunicaciones e instalaciones especiales), diseño de muelle de madera o muelle flotante, proyecto de iluminación y proyecto de subestación.

PROYECTO	PE25 - 004
No. DE DOCUMENTO	PE25 - 004 - PO - 01
FECHA	07/04/2026
REVISIÓN	R - A

RHG INGENIERIA

6.0 CONCLUSIONES Y RECOMENDACIONES.

6.1 Conclusiones.

El procedimiento constructivo propuesto es técnicamente viable y coherente con las condiciones geotécnicas, hidráulicas y operativas de la Laguna de Cuyutlán, siempre que las actividades se ejecuten de manera integral y coordinada.

La correcta ejecución del proyecto depende de la interacción secuencial y simultánea entre dragado, rellenos y estructuras de contención, los cuales no pueden considerarse como procesos independientes, sino como un sistema constructivo interdependiente.

El éxito del proyecto está fuertemente condicionado por la adecuada selección de equipos, la planeación de frentes de trabajo y la coordinación de sistemas productivos, lo que confirma la necesidad de un enfoque constructivo industrializado y altamente organizado.

La complejidad del entorno lagunar, caracterizado por suelos blandos, alta saturación y presencia de materiales no aptos, implica que el control geotécnico, topobatimétrico y constructivo debe mantenerse de manera continua durante todas las etapas del proyecto.

El programa de obra demuestra que la ejecución del proyecto requiere un enfoque escalonado pero traslapado, donde la preparación del terreno, la estabilización y la construcción de infraestructura deben avanzar de forma paralela para optimizar tiempos y recursos.

6.2 Recomendaciones.

Se recomienda establecer un sistema de control topográfico y batimétrico permanente que permita monitorear la evolución de los rellenos, asentamientos y desplazamientos durante todas las fases constructivas.

Es indispensable integrar la programación del dragado y la instalación de tablestacado, evitando desfases que puedan comprometer la estabilidad de los rellenos o generar retrasos en la obra.

Se debe priorizar la implementación de un modelo de ejecución por frentes simultáneos, con coordinación centralizada, para maximizar la productividad y reducir interferencias entre actividades.

Se recomienda desarrollar un plan detallado de manejo de materiales y vertido, incluyendo control de sedimentación, sectorización de recintos y medidas ambientales para evitar afectaciones al entorno lagunar.

Es necesario fortalecer la planeación logística del proyecto, incluyendo infraestructura temporal, suministro de insumos, transporte interno y servicios al personal, dado el alto volumen de recursos humanos requeridos.

Se recomienda incorporar desde etapas tempranas criterios de durabilidad y mantenimiento, considerando el ambiente agresivo marino, con el fin de garantizar la vida útil de la infraestructura.

Se sugiere que el desarrollo del proyecto ejecutivo refine y detalle los procedimientos aquí planteados, sin perder la lógica integral del sistema constructivo, asegurando su adaptación a las condiciones reales de obra.

Asimismo, se debe implementar un sistema de control de calidad riguroso durante el suministro, manejo, almacenamiento e instalación de los perfiles metálicos y tablestacas, verificando tolerancias, alineamientos y condiciones de los elementos antes y durante su hincado.

Finalmente, se recomienda considerar dentro de la programación de obra los posibles periodos de condiciones meteorológicas adversas, como lluvias intensas o eventos ciclónicos, que puedan afectar las operaciones marítimas y el avance de los trabajos, con el fin de minimizar riesgos operativos y retrasos en el proyecto.

MÉCANICA DE SUELOS.

1. MEDIO FÍSICO

El estado de Colima posee una superficie territorial de 5,455 Km2 y se localiza entre las latitudes norte 19°31' y 18°41' así como las longitudes oeste 103°29' y 104°41'.

Por su orografía, el territorio es atravesado por La Sierra Madre del Sur, en particular por las Sierras de la Costa de Jalisco y Colima, así como la Cordillera Costera del Sur, que juntas comprenden el 84% de la superficie del Estado.

El estado de Colima está dividido en tres regiones hidrológicas. La cuenca Río Chacala-Purificación, que abarca los municipios de Minatitlán y Manzanillo; la cuenca Río Armería, que abarca los municipios de Comala, Villa de Álvarez, Coquimatlán y Armería; la cuenca Río Coahuayana que abarca los municipios de Cuauhtémoc, Colima, Ixtlahuacán y Tecomán.

La geología está representada principalmente por rocas ígneas intrusivas (Mesozoico, Cretácico) y extrusivas (Cenozoico, Terciario), que comprenden el 46% de la geología. El resto de los suelos está formado por rocas sedimentarias en un 39% y un 15% de suelos, de origen aluvial o resultados de la degradación de rocas y cenizas volcánicas, entre los cuales se identifican principalmente del tipo Feozem, Litosol, Planosol, Regosol y Fluvisol. Estos suelos se caracterizan principalmente por poseer texturas muy diversas que van desde las graníticas arenosas hasta las sedimentarias arcillosas.

El clima del estado se define como cálido sub-húmedo con lluvias en verano para los municipios de Comala, Cuauhtémoc, Villa de Álvarez, Colima, Coquimatlán, Ixtlahuacán, Manzanillo y las zonas costeras de Armería y Tecomán. Y semiseco muy cálido al interior de los municipios de Armería Y Tecomán.

El municipio de Manzanillo se caracteriza por combinar la planicie costera con zonas montañosas. Forma parte de la fisiografía de la Sierra Madre Sur, la que ocupa la mayor parte del estado y se extiende hasta Oaxaca. Esta provincia fisiográfica tiene relación con la llamada Placa de Cocos, que está en continuo proceso de subducción con relación a las placas de Norteamérica y del Caribe. En consecuencia, debe considerarse que Manzanillo se encuentra ubicado en la zona D dentro de la carta de sismicidad, en la que la ocurrencia de sismos es muy frecuente. El relieve del suelo lo forman los cerros, valles y depresiones, el territorio del municipio se conformó en la era terciaria, desde hace 50 a 60 millones de años.

Las colindancias del municipio son; al norte con Jalisco y el municipio de Minatitlán; al este con los municipios de Minatitlán, Coquimatlán y Armería; al sur con el municipio de Armería y el Océano Pacífico; al oeste con el Océano Pacífico y Jalisco.

La morfología del municipio se caracteriza por una zona montañosa perteneciente a la Sierra Madre del Sur, un lomerío de baja a media altitud de la Sierra de la Costa de Jalisco y Colima, y un valle aluvial irrigado por escorrentías provenientes de las laderas de dicha Sierra, pertenecientes a la cuenca Río Chacala-Purificación, entre los ríos Marabasco y Armería.

La geología está representada principalmente por rocas ígneas intrusivas (Mesozoico, Cretácico) y extrusivas (Cenozoico, Terciario) y suelos de origen sedimentario, principalmente Fluvisol.

La estratigrafía de estas áreas está compuesta principalmente por arenas y arenas limosas de compresibilidad muy baja a nula.

Estos materiales se subdividen en varias capas intercaladas, que presentan grados de consistencia que van de medios a muy densos.

2. TRABAJOS DE CAMPO

La investigación en el área de estudio se realizó por medio de cuarenta sondeos de Penetración de Estándar (SPT) alcanzando una profundidad de 20 m en el lecho marino y descripción del material.

El estudio consiste en hincar una barra-guía de sección tubular equipada con una toma muestras llamado “de media caña”, de dos pulgadas de diámetro. El hincado se realiza por el golpeteo repetido de un martinete de 63.5 Kg., que se deja caer desde una altura de 76.2 cm.

2.1. PROCEDIMIENTO

Una vez localizado el punto exacto de hincado, se procedió de acuerdo con la norma ASTM D-1586, realizando hincados de 15 centímetros hasta completar un avance de 45 centímetros contando el número de golpes por cada avance de 15 cm.

La resistencia a la penetración estándar, denominada “N”, es el número de golpes requerido para un avance de 30cm., contados dentro de una frecuencia de golpeo no mayor a 30 impactos por minuto.

Cuando el número de golpes necesario para penetrar 15 centímetros es igual o superior a 50, el ensaye se da por terminado

2.2. MUESTREO

Durante el procedimiento del sondeo se retira el penetrómetro y se toma una muestra que será más tarde analizada en el laboratorio como complemento del estudio de identificación de los materiales componentes, determinación de sus características físicas y cálculo de su capacidad portante.

Las muestras recuperadas se guardan en recipientes herméticos, estos son etiquetados para su precisa identificación con la siguiente información: Tipo de sondeo; Localización de la prueba; Número de muestra; Profundidad a la que se obtuvo; Nombre del operador responsable del estudio; Fecha y Hora; Condiciones del clima.

3. TRABAJOS DE LABORATORIO Y GABINETE.

A todas las muestras recuperadas se les determinó su contenido natural de agua, y se realizó su clasificación visual y al tacto. Selectivamente se efectuaron pruebas de límites de consistencia, porcentajes de finos (lavado) y granulometría por mallas, atendiendo al tipo de material que se tratara. Con estos datos se obtuvo la clasificación del sistema unificado de clasificación de suelos (S.U.C.S.) de los diversos materiales.

3.1. LABORATORIO

Las muestras obtenidas se analizan en laboratorio para su identificación y determinación de sus características físicas, de acuerdo con los siguientes procesos:

a) Determinación de la humedad natural. Diferencia en pesos (antes/después) de una muestra secada 24 horas en horno eléctrico.
b) Identificación del tipo de suelo de acuerdo con la clasificación SUCS. Granulometría por Mallas y Valores Índice (Límites de Atterberg).
c) Determinación del contenido de finos menores a 0.0750mm (malla No.200), por medio de pruebas de lavado o análisis hidrométrico, según convenga al proyecto.
d) Determinación de la resistencia a esfuerzos cortantes en materiales cohesivos, por medio de pruebas en cámara triaxial o pruebas de corte directo (si son requeridas por el proyecto).

Los resultados sobre las características litológicas y cualidades físico-mecánicas de los diferentes estratos, aparecen detallados en los reportes de las pruebas de campo y laboratorio del siguiente capítulo.

4. INFORMES DE LAS PRUEBAS DE CAMPO Y LABORATORIO.

Los registros de laboratorio completos se encuentran en el Anexo Mecánica de Suelos.
